> The concise and concrete character of the word neurasthenia gives it a satisfying definiteness. This depends to a large extent on its classical and somewhat graceful sound. Not only is it graceful to the ear, but it is grateful to the mind of the patient who suffers and longs to know from what, who longs to have a name for that which he, or more often she, feels must be a more definite malady than is suggested by the commonplace designation of nervous weakness. But its use has extended far beyond the needs of the patient and indeed did so from the first. It has firmly established itself in current clinical terminology. Men are apt to rest on it as they would not on its English equivalent. If they do not actually think that they have found the malady from which the patient is suffering an influence is often exerted on them (of which they are unconscious) which lessens the tendency to go further in the search for the whole morbid state. The Royal College of Physicians of London could not include it in their nomenclature of disease. And yet it is now one of the most common of medical words in every language.

Sir William insists that words are our servants, but that they often exert a very masterly influence on us, none the less effective because we are not conscious of it. This is only, of course, a familiar exercise of what philologists have long known as the tyranny of words. With regard to neurasthenia, anyone of reasonably wide experience in hospital dispensaries in large cities must know how many sins of diagnosis the word serves to cloak. Everything from mild heart disease, incipient kidney disease and beginning tuberculosis, with their well-known tendencies to produce tired feelings, up to and including the severer forms of heart and kidney disease, and even such serious conditions as Addison's disease or diabetes or organic nervous disease come labeled with that wonderful word neurasthenia—more grateful far than Mesopotamia. It has quite displaced the word malaria, which used to cover so many of these conditions fifteen or twenty years ago, but which fortunately now has sunk into more or less innocuous desuetude, though malaria's replacement by another equally vague term does not argue much for general advancement in medical diagnosis.

Neurasthenia, however, is only one of a group of words that serve to express very indefinite diagnostic ideas, yet give a certain amount of satisfaction to patients, and apparently also to physicians. Biliousness is another one of these words. Any physician who analyzes the next ten cases he sees in which patients say that they are bilious will find, we venture to say, at least six different conditions included under this term. Whenever a patient has acid or bitter eructations, the word bilious is prone to be used in describing the affection, and even physicians do not generally realize that the bitter tasting material which is sometimes regurgitated, is not bile but peptone—an intermediate stage of stomach digestion.

It has been pointed out that the three words most popularly used for the description of common affections—rheumatism, catarrh and gout—signify according to their etymologic meaning exactly the same thing. Catarrh means an increase of secretion from its root, the Greek verb "to flow." Rheumatism has the same derivation; gout is probably from the Latin word "gutta," a drop, and also represents an increase of liquid in a part. We are sometimes prone to be humorous at the expense of a former generation of physicians who spoke of many affections as "rheums," and even classed all of the eczematous conditions, and it may be said most other skin diseases, under the term "salt rheum." There is no doubt, however, that our generation is leaving many openings in just the same way for the physicians of the future to exercise their wit. If the use of these lax general terms could be eliminated, there would be much less room for the wonderful cure-alls that now are so glibly advertised, so that there are good reasons for special efforts to get away from the tyrant words.

USEFUL BACTERIA.

One is apt to become so deeply impressed with the fact that bacteria are producers of disease, that one may lose sight of the equally important fact that there are groups of bacteria which are useful to mankind and even essential to our well-being. The most important group in this large class of micro-organisms is that of the normal inhabitants of the intestinal tract. It is well known that the intestinal tract of most of the warm-blooded animals is literally swarming with bacteria of various kinds, but their importance to the host is often greatly underestimated. Indeed, it has been thought that the body would be better off without them, but this seems to be a mistake, as is made evident by the following facts pointed out by Strasburger.[1] Experiments on birds and mammals indicate that the more highly organized animals can not live very long if all bacteria are excluded from the intestine. This is especially true of those animals which live largely on a vegetable diet, because in man and many of the highly organized warm-blooded animals the intestine does not secrete an enzyme that is capable of dissolving cellulose, and thus liberating the nutritive material inclosed in the vegetable cells, as is the case, for instance, in snails. The coarser vegetable foods might, of course, be reduced, by mechanical means, to such a fine state of subdivision as to do away with the necessity of dissolving the cell membranes in the process of digestion. This task is said to be performed in man, by the *Clostridium butyricum*, and in the herbivora by the *Bacillus amylobacter*, which are normal inhabitants of the intestinal tract, and are probably the same organism.

Most foodstuffs are, under certain conditions, decomposed by bacteria, and this decomposition may be either putrefaction or fermentation. In the small intestine the conditions for putrefaction are most favorable, on account of the temperature and the richness in proteid of the contents, but it is prevented by fermentation by the carbohydrates, caused by the *Bacillus lactis aerogenes* and the *Bacillus coli communis.* These organisms serve thus as a protection for the body, because if putrefaction were allowed to go on in the small intestine it would soon cause symptoms of intoxication, due to absorption of toxic products. It must be remembered that putrefaction in the small intestine would be quite different from that going on in the large intestine, because in the former are found partly digested proteids, which mostly are absorbed before the food reaches the large intestine. In addition to the protection against putrefaction and the consequent auto-intoxication, the fermentation in the small intestine is said to kill many pathogenic bacteria which are taken in by the mouth and pass through the stomach unharmed.

Another important group of bacteria is constituted by the nitrifying organisms. It is well known by the expert agriculturalists that a soil which is poor in combined nitrogen is not suitable for vegetation. This soil could be improved by adding compounds containing nitrogen, but that is impracticable. Another and more practical method of enriching this soil consists in growing in it the leguminous plants, especially clover. These plants have the power of increasing the nitrogen content of the soil, but it has been found that the plants alone do not possess this power. It is necessary that the soil should contain nitrifying bacteria, most important of which is the *Bacterium radicicola.* This organism grows in the nodules on the roots of these plants, and builds up nitrates from atmospheric nitrogen. The nitrates are taken up by the plant, and when the plant dies they get into the soil and render it more suitable for other vegetation. In Germany and other European countries, large tracts of barren land have been made productive by inoculating the soil with the *Bacterium radicicola,* and growing leguminous plants in it for several years. Our own agricultural department at Washington is now carrying on experiments in the hope of improving some of the arid land of our western states.

PNEUMONIA AND SOFT COAL.

In the monthly bulletin of the Connecticut Board of Health, the secretary, Dr. Lindsley, makes the point that some of the increase of pneumonia during the winter just closing is due to the increased use of soft coal. This suggestion is perhaps worthy of some thought. There is no doubt that since the great coal strike of last year there has been an increased usage of soft coal, and the high prices that have been kept up since then by the operators have a tendency to make this more or less a permanency. It will be a great misfortune, not only in an esthetic but possibly also in a sanitary point of view, if the price of hard coal is maintained, putting it out of the reach of many who formerly utilized it and tempting many others who perhaps could still afford it, but who through motives of thrift will more or less discontinue its use. It is possible, of course, that the theory that soft coal is responsible for the increase of pneumonia is overstated, but still if it is at all a contributing cause even of the loss of a few lives, it is not a matter for neglect.

CANCER AND FROZEN MEAT.

A rather curious inquiry was made in the British House of Commons a few days ago, asking whether the use of frozen meat—which has become a considerable portion of British diet—was in any way responsible for the increase of cancer. It shows the public interest in this subject, though the possibility of frozen meat having anything to do with cancer is about as remote as that of the responsibility of tomatoes or other articles of food which have been thus credited in the past. Of course, the molecular changes which take place in the process of freezing may deteriorate the nutritive qualities of meat to a certain extent, but so far as we have been able to learn or observe, cancerous disorders are not more frequent among the Eskimos, who for a large part of the year, from necessity, live almost exclusively on frozen meat, than among other people of the globe. Of course, the field of observation there is limited, but if frozen meat were really responsible for many of these evils, this peculiarly hardy section of the human race ought to have shown its effects.

X-RAY IN LEUKEMIA.

That the *x*-ray in some mysterious way produces tissue changes that may result in the disappearance of superficially situated pathologic lesions or may lead to irritation or burning of the healthy skin, is well known. Of its effects on deeper structures, both in conditions of health and of disease, much less is known. Experience alone can show whether it is efficacious in the case of tumors lying deeper than the skin, and whether any harm to normal structures, analogous to the burn of the skin, may result from its long-continued use. A few months ago Senn[1] reported on the remarkable effects of the *x*-ray in leukemia. In the present number of The Journal is reported a carefully recorded case by Brown, in which a change for the better that is truly astonishing is described. Brown cautiously refrains from declaring his case permanently cured. This is wise, for we know the tendency there is in leukemia, pseudoleukemia and pernicious anemia to spontaneous improvement and relapse, even with no treatment whatever. Pseudoleukemia, also, under the influence of an intercurrent erysipelas, may be symptomatically cured. The blood picture, the spleen and glands as regards size, the subjective symptoms in leukemia may all show decided improvement for a time. But these changes seem to be quantitative rather than qualitative, and sooner or later the relapse occurs. It would be wise, therefore, in all instances of marked improvement in leukemia, to make not only a count of the number of the leucocytes, but a differential count as well. A large percentage of myelocytes in the blood of a supposedly cured leukemic may show that the underlying condition has not been done away with. While reports of any therapeutic measure that will produce such striking benefit as the *x*-ray in leukemia are valuable, conclusions should not be too hastily drawn, and each case should be carefully studied and watched for a long period.

THE DANGER OF BURIAL ALIVE.

A bill was recently introduced in the Massachusetts legislature providing for the compulsory employment of certain specified means to prevent premature burial. The legislator seems to have the idea that many persons are buried alive, and that precautions are necessary to prevent such accidents. Our contemporary, the *Boston Medical and Surgical Journal,* very justly criticises this proposed legislation, and gives good reasons why it should not be enacted. The chances of premature burial, according to the best medical opinion, are very slight, save, perhaps, in periods of panic and of epidemics, and the sensational stories which appear in the secular press and which have given rise to the morbid fear—which is the real instigator of the bill—have seldom any basis of fact. The common use of preservative fluids in the body before burial would certainly prevent any possibility of resuscitation, and yet we have never heard of any involuntary manslaughter being committed by embalmers. A man can not rise in his grave with his arteries and veins filled with an arsenical solution, and this is the actual condition of things in a very respectable proportion of burials. While the idea of being buried alive is most distressing, it is improbable that there could be much agitation or suffering, because trance conditions are very seldom if ever associated with consciousness, and the lack of air in the coffin would quickly asphyxiate and extinguish any spark of life that might remain, probably without any suffering whatever. This, however, does not make it any more desirable to be buried alive, but it is safe to say that the opportunity for such is hardly to be calculated on. One thing, however, is worth consideration, and that is that there is occasionally a case in which greater care should be exercised in making out the death certificate. The practitioners should never neglect due personal inspection or examination. It should be less common for death certificates to be signed by physicians without any personal knowledge of the actual state of affairs; while the consequences are not likely to be serious, it is a dereliction of duty on the part of the physician who thus makes out the certificate. The signs of death and the indications of the history of the case are sufficiently certain to enable any competent physician to decide either that he may safely give his certificate, or that, if he feels doubtful, further evidence is necessary. The latter, however, would be a rare necessity.

GOITER IN THE STATE OF WASHINGTON.

Some months ago the editor of the *Medical Sentinel* published an editorial inquiry as to the prevalence of goiter in the northern Pacific states, especially Washington. In reply, Dr. Thomas W. Musgrove, Mission, Wash., describes[1] the conditions in the Wenatchee and Puyallup valleys in that state. In Mission, where he practices, goiter is more common than in any other part of the state. Whole families are infected, and animals—dogs, lambs and pigs—suffer from this endemic enlargement of the thyroid. Nearly every woman who has lived there long and who is pregnant has her neck enlarge *pari passu* with her abdomen. In Puyallup Valley most of the cases appear in young girls, and are cured if treated early with tincture of iodin externally and hydriodic acid and phytolacca internally. It seems more particularly to affect those who drink the water from the running streams that come from the mountain glaciers, while those who drink from wells where the water has been filtered through gravel are less likely to be affected. Musgrove is confident that there is some mineral constituent in the water that is the cause of the condition. He finds a rather peculiar condition of the urine. The specific gravity is high, 1025 to 1035, phosphates are abundant, and the carbonates are so marked that the addition of nitric acid to urine in which boiling had caused an albumin-like precipitate, clears up that precipitate with such a sharp effervescence from the escaping carbonic acid gas as to create a decided commotion in the fluid. This condition is found in the perfectly healthy inhabitants of this valley. The editor of the *Medical Sentinel* thinks that Dr. Musgrove is a little too optimistic as to the possibility that the cause of goiter may be discovered, since much work has been done abroad and without very definite results. The absence of iodin in the water seems to be the only fact that is apparently correlated with the disease. He remarks that Dr. Musgrove's observation that the internal use of hydriodic acid relieves these cases is suggestive. It would seem that with such a localized endemic condition, something might be done to determine more definitely the pathology of goiter. We trust that the scientific men of the profession in Washington who have opportunities to observe and laboratory facilities for experimentation will do their best to elucidate the subject. Further data on the subject are very desirable.

WATER PURIFICATION BY BACTERIA.

In a recent article, Prof. John H. Long[1] reviews some of the facts in regard to bacteria, especially as regards water purification. Most of his data were drawn from the testimony brought forth in the investigation relative to the purification of the Chicago sewage in the Illinois River. As this matter is still in litigation, we need not here discuss the point at issue, but will simply allude to one point which Long mentions, which is at least suggestive. Referring to the success of bacterial fertilization of land, he says:

> With such experience before us I believe it is not too much to hope that some day someone will undertake the sanitary inoculation of streams as a means of hastening or completing the destruction of organic matter. Indeed, a suggestion essentially in this line was thrown out by Dupre sixteen or seventeen years ago, but it attracted no attention, as too little was then known of the conditions or the extent of bacterial action.

Professor Long admits that the question is a complicated one, and that there are problems in it that may be difficult of solution. The element of time enters into the question of the destruction of pathogenic bacteria, and the flow of the river must not be too rapid. He suggests, however, that we are coming to the point where the flow of some of our large rivers will have to be checked or governed to avoid the disastrous floods which occur, and it may be that the storage reservoirs primarily designed to hold up the floods may become purification reservoirs. It is probable that there is something in his suggestion. The contamination of river waters has long been a serious question in many older countries, and it is beginning to be serious in this country. Something will have to be done if we are to preserve the purity of the water supplies and the attractiveness of our flowing streams, especially in our more thickly settled regions. If it is possible by bacterial treatment to remedy some of the threatening evils, it is a matter worthy of very serious consideration not only by scientific men but by the state. When the full testimony is in and the facts fully developed as to the points of dispute now being litigated between the State of Missouri and the State of Illinois, we will perhaps have facts that will help to indicate the course to be pursued. We realize the importance of bacteria, at least so far as the pathogenic forms are concerned, but we are very apt to ignore the beneficial effects of a far greater number of these microbes.

OVAL BLOOD CORPUSCLES IN MAN.

The oval or elliptical red blood corpuscles are generally supposed to be found in mammals only in the group to which the camel and its close congeners belong. It is interesting, therefore, to record a case of what we must consider an anatomic or physiologic sport of this kind in the human species. Mr. Melvin Dresbach[1] reports the case of a healthy young mulatto in the University of Ohio in whom it was accidentally found that the red corpuscles of his blood were elliptical instead of round. The case was carefully investigated for a period of four months, specimens being taken at various intervals, and in every specimen many cells of abnormal shape were noted. Dresbach says the erythrocytes were distinctly elliptical, slightly biconcave, non-nucleated cells which did not adhere in rouleaux. In many of these the biconcavity was scarcely perceptible. The estimate was that fully 90 per cent. of the red cells lacked the circular outline of normal human corpuscles, and that the elliptical shape was not modified in any way under the pressure of the cover glass. In every other respect they seemed to correspond with the normal red blood cells of the ordinary individual, except in the slight degree of biconcavity. A large number of the corpuscles were measured and extremes and averages are reported. The shortest width observed was 3.9 microns, the greatest, 4.8; the shortest length was 8.5 microns; the greatest, 10.7. The average length was 10.3 microns and the average width 4.1 microns. It would appear, therefore, that in this individual the elliptical blood cells formed the mass, and that the proportion of length and width was about 2.5 to 1. These proportions differ widely from those of the average normal red blood cells, which average 7.2 to 7.8 microns in diameter. The thickness was practically the same as that of normal red blood corpuscles, the number was 5,000,000 per cubic millimeter and the quantity of hemoglobin was normal. The colorless corpuscles presented no peculiarities. It is a rather curious fact that the brother of the individual presenting these peculiarities had perfectly normal corpuscles. The case must be an exceedingly rare one, and further details as to the physical condition would be desirable. Just what causes the peculiar variations in this case is left entirely a matter of conjecture. It would be rather a strain to call it a reversion to an earlier type, and the fact that it occurred in an individual of mixed blood does not clear up the case. The observation seems to be well accredited, appearing as it does in a scientific journal and occurring in a leading state institution.

HOW TO EAT.

In a recent issue of THE JOURNAL "The Ethics of Eating" was editorially noticed and the importance of the element of pleasure and enjoyment in the taking of food emphasized. An article in the *Nord Medical,* June 1, 1903, by an experienced French physician, Dr. A. Monteuuis of Dunkirk, still further brings out this fact. He emphasizes that none of the organs of the body is so sensitive to the action of the nervous system and so directly sensitive as the stomach. Any emotion or annoyance may be sufficient to arrest the gastric digestion and entail next day a headache, pains in the limbs or other disturbance. Worry or overfatigue is liable to produce the same effects. The palpating hand can feel the contraction of the stomach under the emotion. Some mothers never digest a meal properly, because they fret over their children's table manners or over household cares. Overwork, especially moral and mental, by fatiguing the nervous system, reacts on the stomach. The organ in these cases is not diseased nor capricious, but is merely a victim to the causes of irritation or depression which exhaust, irritate or at least hinder its proper functioning. We are liable to forget the important part played by the inhibiting influences emanating from the nervous system on the vital processes, and particularly on the digestion. One fatigued nerve center reacts on another, and so on, inducing a whole train of inhibitions. This solidarity of the nerve centers gives the key to keep them in tone. Disagreeable impressions, depressing the nervous system, inhibit the digestive processes. Gayety, on the other hand, promotes them. The preponderant influence of the nervous system is displayed equally promptly in the response to peaceful, cheerful surroundings as in the inhibitions from worry. Monteuuis suggests that the physician should resume his old position in society as the educator, and should preach in season and out of season against the race for wealth and social position which is ruining the digestion of modern men and women. The moralist has been teaching for ages that money and social position do not bring happiness, that the sweetest pleasures the world has to offer are those of simple, happy family life. The medical profession should bring its influence to bear on the same subject and show the public that this alone is the key to normal digestion and health, both of mind and body. The will and character are strengthened by the effort to leave cares and worries outside, and to preach and practice light-heartedness in the family circle, above all at the table. In the treatment of a neuropath the physician should impress on the family the necessity for this nerve hygiene by gayety at the table. If he is unable to secure this, all his other measures will prove futile. Our profession has been remiss in allowing people to get into the present strenuous modes of living without being more fully informed and warned of its almost inevitable health penalties.

---

[1] Science: March 18, 1904.

HALF FARE TO ATLANTIC CITY.

As is announced under General News this week, a rate of one fare for the round trip to the Atlantic City session of the American Medical Association, June 7 to 10, 1904, has been granted by the Trunk Line Association. This good news is received by telegraph as we are going to press. It means much for the session. The Trunk Line Association also advises other passenger associations to grant the same rate, and there is good reason to believe that they will do so. The Trunk Line Association has been very conservative in previous years, and has granted only a one and a third fare rate. Following its lead this year, it may be relied on that the other associations will grant a half-fare rate—at least throughout the larger part of the country. The effect on the attendance at the Atlantic City session will be marked, and many other signs point to a session which shall be a record-breaker in point of size as well as in other particulars.

Medical News.

CALIFORNIA.

Smallpox at Oakland.—After the disease had run its entire course seven cases of smallpox were discovered in one family in Oakland, and the house was then quarantined.

Health Board Dismissed.—As a result of differences of opinion regarding smallpox policy, the board of health of Petaluma was summarily dismissed from office, and a new board appointed, which organized with Dr. Israel M. Proctor, president, and Dr. Harry S. Gossage, secretary.

Railway Hospital at Los Angeles.—The Santa Fe System has decided to complete its chain of hospitals from Albuquerque to the coast by erecting a hospital in Los Angeles, to cost $100,000, with accommodation for 75 to 100 patients, to be under the charge of Dr. Norman H. Morrison, chief surgeon of the road.

Hospital Attaches Uniformed.—Chief Surgeon George F. Brackett of the city emergency hospitals has made important innovations. The latest is that all attaches appear for duty in white duck uniforms, the insignia of the office of each being neatly embroidered on the military collar of the service coat. The purpose is to prevent confusion and to classify the employes, that strangers and patients may know whom they are addressing.

Bubonic Plague.—The diagnosis of plague in cases 115, 116 and 117 has been bacteriologically confirmed.——A fatal case of supposed plague in a white woman occurred near Concord, Contra Costa County, February 29. This is the third fatal case from this locality.——The supervisors of San Francisco have appropriated $2,000 from the urgent necessity fund, to be used in improving the sanitary condition of Chinatown.——The Danysz virus is now being used in San Francisco and Contra Costa in the war of extermination against rats. (This method is described under Foreign News this week.)

CONNECTICUT.

Diphtheria Closes Schools.—The public schools at Noroton were ordered closed, March 9, owing to the prevalence of diphtheria.

Donation to Hospital.—Bishop Tierney of Hartford has given $5,000 of the $15,000 presented to him by the priests of his diocese, to St. Francis Hospital, Hartford.

The State's Pneumonia Record.—Of the total of 1,384 deaths reported in February, 217, or 15.68 per cent., were caused by pneumonia. In January 1,428 deaths occurred, of which 213, or 14.91 per cent., were due to this cause.

Compromise Smallpox Bill.—After pending for nearly two years the bill of Dr. Charles W. S. Frost, health officer of Waterbury, for services rendered in the smallpox epidemic, amounting to $3,830, was settled for $2,500.

National Guard Reorganization.—Under the reorganization of the medical department of the National Guard, Colonel Schulze made the following nominations for assignment to the First Infantry, March 15: Surgeon-major, Dr. John B. McCook; surgeon-captain, Dr. Heman A. Tyler, and surgeon-lieutenant, Dr. William H. Van Strander, all of Hartford.

New Haven Personals.—Dr. Henry H. Smith has taken a twenty-day trip to the Danish West Indies.——Dr. Nicola Mariani fell on a sidewalk, March 7, and fractured his left arm.——The position of medical examiner for the Yale gymnasium has been abolished, thereby dropping Dr. Jay W. Seaver, who for 25 years has so served. Dr. William H. Callahan, who is in charge of the United States Army dieting squad, will be medical assistant in the gymnasium.

DISTRICT OF COLUMBIA.

Hygienic Cantata.—At the Washington Saengerbund concert, March 20, a notable feature of the performance was a cantata, "Hymne an Hygeia," composed and orchestrated by Dr. John C. Hemmeter of Baltimore.

The Pneumonia Exception.—Washington has not shared in the destructive mortality from pneumonia which has obtained generally throughout the country. The pneumonia deaths for February were less than for February, 1903.

Reciprocity in Medical Licensure.—The board of medical supervisors of the district has submitted to the commissioners a draft of a bill to authorize the board to issue licenses to practice medicine to licentiates of corresponding boards of other jurisdictions.

New Providence Hospital Opened.—New Providence Hospital, recently completed at a cost of $1,000,000, was opened, March 16. with formal ceremonies, including addresses by Cardinal Gibbons, Secretary of War William H. Taft, Surgeon-General George M. Sternberg, Dr. John W. Bayne, president of the medical board, and others. The hospital has accommodations for more than 500 patients, and there are over 100 private rooms and apartments. Special buildings have also been provided for a nurses' home, and an isolation hospital.

Conditional Department of Public Health.—An ordinance has been adopted by the board of trustees of Columbian University, to go into effect when an endowment fund of $200,000 has been pledged, or a guarantee fund of $10,000 a year for five years has been subscribed, creating a department of public health in which the following subjects shall be taught: Hygiene, Dr. George M. Sternberg; sanitary chemistry, Dr. Harvey W. Wiley; bacteriology, Dr. James Carroll; medical zoology, Charles W. Stiles; sanitary administration, Dr. William C. Woodward; sanitary inspection, Dr. Walter Wyman; dangerous occupations, Charles E. Monroe; comparative medicine, Daniel V. Salmon; insects as agents in the transmission of disease, L. O. Howard; international law, Justice David J. Brewer; constitutional and statutory law, Henry St. G. Tucker, and administrative law, George W. Scott.

FLORIDA.

A Year and a Day for Absent Treatment.—In the United States Court, at Jacksonville, March 1, Mrs. Helen Wilmans-Post, an "absent-treatment" healer by the correspondence method, was convicted of using the mails for fraudulent purposes, and was sentenced to imprisonment in the penitentiary at Nashville, Tenn., for a year and a day. An appeal was taken and granted, and a bond of $5,000 given.

Sickness Statistics.—Dr. Joseph Y. Porter, Key West, state health officer, in his annual report calls attention to the efforts of the State Board of Health to obtain information as to the prevalent diseases in the state, that intelligent study may be made the causes which produce them. He urges the physicians of the state to report all cases of illness which necessitate absence from work or business or confinement to the house. From these reports he can make up a consolidated report which will be of value in determining the health status of the state.

Smallpox in Florida.—Dr. Hiram Byrd, special agent of the State Board of Health, in his report to that body, states that in 1903 he investigated 23 reported outbreaks of smallpox, exclusive of Jacksonville and Pensacola. In 3 instances the alarm was false, and in 6 the source could not be made out. Of the remaining 14, 7 originated in Alabama, 3 in Georgia, and one each in South Carolina and Indiana. Two cases originated in Florida. He draws the following conclusions:

> 1. Once an individual is rendered immune against smallpox he is immune for life.
> 2. In a great majority of cases one vaccination produces that immunity.
> 3. One successful vaccination may, on the other hand, produce only a partial immunity, and in such cases the individual may subsequently contract smallpox or be successfully vaccinated.
> 4. In a great majority of cases one attack of smallpox produces complete immunity.
> 5. One attack of smallpox may, on the other hand, produce only partial immunity, and in such cases the individual may subsequently contract smallpox or may be successfully vaccinated.

GEORGIA.

Fund Almost Complete.—Less than $800 now remains to be subscribed to ensure the founding of a hospital in Albany.

Addition to Macon Hospital.—Macon Hospital Association has decided to build an additional wing to the hospital building, which will contain 18 rooms.

Smallpox.—Cuthbert and Mansfield report the disease as epidemic.——In the Covington convict camp a case has appeared, and all the convicts have been vaccinated.

Personal.—Dr. Walter A. Crowe has been elected a member of the medical board of Grady Hospital, Atlanta, vice Dr. Virgil O. Hardon, deceased.——Dr. B. S. Gostin, Macon, was examined for the position of assistant surgeon, Georgia State Troops, March 3, at Augusta. He has been appointed assistant surgeon and assigned to the Second Infantry.——Dr. Joseph E. Johnson, Elberton, had his arm broken in a runaway accident, March 7.

ILLINOIS.

Hospital for Sick Insane.—The Board of County Commissioners of Cook County has authorized the transformation of the old consumptive hospital at Dunning into a hospital for the sick insane, at a cost estimated at $10,000.

To Avoid Publicity.—The East St. Louis Medical Society has adopted the following resolution:

> *Resolved,* That the East St. Louis Medical Society request the reporters of this city to omit the names of any physician who may be called in accident cases, or who may perform operations.

Personal.—Dr. Theodore N. Rafferty, Robinson, has returned from a vacation of a month in the south.——Dr. Elbert J. Clark, Winnebago, has decided to retire from practice, and to travel in hope of benefiting the health of Mrs. Clark.——Dr. James I. Wernham, Marengo, has started for Vienna.——Dr. and Mrs. James Warren Van Derslice, Chicago, sail for Europe March 26.

Analyzes Water Supply of State.—The Illinois State Board of Health has completed an analysis of the drinking water in all cities of the state having a population of more than 5,000. The supply was found to be "good" in Aurora, Belvidere, Belleville, Braidwood, Batavia, Beardstown, Blue Island, Bloomington, Chicago Fourteenth Street tunnel, Chicago Lake View tunnel, Clinton, Dixon, Freeport, Fairbury, Galesburg, Geneseo, Havana, Hoopeston, Jerseyville, Lake Forest, La Grange, Maywood, Oak Park, Ottawa, Pontiac, Princeton, Pana, Rockford, Savanna, Springfield, Sycamore and Taylorville. It was found to be safe, although not sufficiently pure to be classed as good, in Chicago Avenue tunnel, Chicago, Decatur, Danville, Evanston, Galena, Monmouth and Paxton.

Chicago.

Hektoen Goes Abroad.—Dr. Ludvig Hektoen, head of the McCormick Memorial Institute for Infectious Diseases, will go to Europe early next month to study, and to secure information for use in the construction of a large hospital for infectious diseases, which is to be erected in the near future in Chicago.

Plan Campaign of Education.—The National Anti-Tuberculosis Association was incorporated at Springfield, March 17, by Dr. Walter B. Metcalfe, Rev. Frank M. Carson and others, to distribute information regarding the disease. A free clinic will be established in the Chicago down-town district. It is planned to tender the services of lecturers to those who desire to know more of the subject.

Pneumonia Still Far in the Lead.—Pneumonia caused 137 of the 578 deaths for the week ended March 19, a percentage of 23.72; consumption follows with 74 deaths; then come violence, with 33; heart diseases, with 32, and nervous diseases with 28. The death-rate for the week was at an annual rate of 15.44 per 1,000, higher than that of the previous week, but below that of the corresponding week of 1903.

Medical Society Endorses Emergency Hospital.—At the meeting of the Chicago Medical Society, March 16, the project of the Iroquois Memorial Association to erect an emergency hospital in the business section of the city was approved and the following resolutions were unanimously adopted:

> *Resolved,* That the Chicago Medical Society approve and unqualifiedly indorse the action of the board of trustees of the Iroquois Memorial Emergency Hospital in their generous effort to give to the people of Chicago a modern, fully equipped and endowed hospital capable of rendering prompt assistance to those cases of unexpected injury and sickness which are of daily occurrence, and be it further
>
> *Resolved,* That we, as a society, tender to the hospital our counsel, advice and professional services whenever required.

KENTUCKY.

Personal.—Dr. William W. Ray has retired from the superintendency of the Western Kentucky Asylum for the Insane, Hopkinsville, and has been succeeded by Dr. Milton Board, Jr., Hardinsburg.

A Change of Management.—Beginning with the issue of January 1, the *American Practitioner and News* passed under the ownership and editorial control of Drs. Fouche W. Samuel and Argus D. Willmoth of Louisville.

Appointments.—Governor Beckham has made the following appointments, which were ratified by the senate before its adjournment: To the State Board of Health, Drs. Joseph M. Mathews, Louisville, George T. Fuller, Mayfield, re-appointed for six years: Dr. Frank O. Young, Lexington, vice Dr. Leslie L. Robertson, Middlesboro, resigned; visitors to Central Asylum for the Insane, Drs. Maverell K. Allen, Benjamin W. Smock and W. C. Vander Espt, Louisville.

Schools' Swindled.—Several of the medical schools in Louisville have recently been imposed on by a man calling himself "Dr. Jos. C. Dougherty." He would matriculate to do postgraduate work and offer a check in payment for a much larger sum than the fee required, and obtain the change. These checks were made payable to Dr. Jos. C. Dougherty, and were drawn on the Jefferson Bank of St. Louis, signed by Daniel J. Dougherty. All the checks were returned with the statement that they were forgeries.

MARYLAND.

Baltimore.

High Death-Rate Continues.—The death-rate continues high, 215 last week against 184 in the corresponding week of last year. This represents an annual rate of 19.51 per 1,000. Pneumonia caused 32 and consumption 29 deaths.

To Make Up Fire Loss.—An appropriation has been proposed for the Johns Hopkins Hospital in the state legislature. This will not, however, equal the loss, and if the Rockefeller plan fails, it is probable an appeal will be made to the country. It is believed that there would be a generous response for this noble institution in its misfortune.

MASSACHUSETTS.

Few Thousands Yet Needed.—The contributions to the $100,000 fund for re-building the Convalescent Home of the Children's Hospital at Wellesley Hills, now amount to $93,077.

Personal.—Dr. George W. Gale, East Saugus, sustained serious injuries by a fall on the ice in Cliftondale, March 4.——Dr. William H. Grainger, East Boston, who refused to resign from the Board of Trustees of Pauper Institutions, was removed by the mayor, March 11.

Infection by Visiting Servants.—The Woman's Health Club of Boston, on March 18, discussed the spread of disease among families by means of the visiting domestic servants. "Hygiene in the Public Schools" was the topic of a paper read at the same meeting by Dr. Alice M. Steeves.

Bequests.—By the will of William Littlefield, Lexington, the following hospitals benefit: Boston Lying-in Hospital, $3,000; Children's Hospital, $5,000; Willis Consumptives' Home, $5,000; New England Hospital for Women and Children, $3,000; Washington Home (for dipsomania) $5,000; and Massachusetts General Hospital, $5,000. The New England Deaconess Home and Hospital will receive $200 annually from the estate of Alfred M. Williams of Brookline.

From Sanitarium to Sanatorium.—The Sharon Sanitarium has changed its name to Sharon Sanatorium. This institution has proved very useful in its care of incipient phthisis, especially among women, who are received for $5.00 per week. Dr. Frederick I. Knight is the consulting physician, and Dr. Walter A. Griffin the resident physician. Among the newly-elected directors are Drs. Vincent Y. Bowditch, Robert W. Lovett and L. Vernon Briggs; Dr. Bowditch being the medical director and the one whose name has been most closely associated with the institution since its establishment in 1891, the first of its kind in New England.

NEW JERSEY.

The Revival of a Blue Law.—There have been so many cases of contagious diseases in Passaic during the last year that have not been reported that the board of health has decided to pay ten cents to the physician for every case of contagious or infectious disease that he reports.

Cooper Hospital Must Pay Taxes.—The Court of Errors and Appeals of New Jersey has decided against the Cooper Hospital estate, and sustained Camden City in assessing properties of the estate not used for hospital purposes. The hospital thus may be deprived of considerable revenue. There is a claim against the estate for $30,000 for back taxes. The trustees asserted that as a charitable institution, under its charter all properties from which revenue is derived to maintain the same is exempt from taxation.

Examination for Sanitary Inspectors.—The members of the board of examiners appointed to test the fitness of applicants for appointment as sanitary inspectors, met in Princeton, March 16, and an organization was effected by the selection of Dr. William H. Murray, Plainfield, as chairman, and Dr. A. C. Hunt, Trenton, as secretary. The remaining members of the board are M. N. Baker, C.E., of Montclair, D. D. Chandler, health officer of Newark, and D. C. Bowen, assistant state inspector of food and drugs, of Asbury Park. Regular examinations will be held on the first Wednesday of June and December.

NEW YORK.

Personal.—Dr. F. C. N. Jerauld has been appointed a member of the Niagara Falls Board of Health, and Dr. Walter A. Scott has been elected health officer.

For Insane Hospitals.—A bill asking for the appropriation of $1,203,000 for the construction of buildings, repairs and improvements at the state hospitals has been submitted to the legislature.

Why Has Middletown a Low Birth Rate?—The state health commissioner, Dr. Daniel Lewis, is seeking the reason for the low birth rate of Middletown city. Although it has a population of 15,000, during the last five years there have been only 757 births, while the deaths number 1,358.

Improvement at Watertown.—The typhoid fever situation at Watertown shows a marked improvement. The number of cases now in the town is less than 500, and the cases reported daily show a marked decrease in number. Arrangements are practically completed for supplying the town with pure spring water.

Cancer Research Abandoned.—After spending $100,000 the state has abandoned its attempt to find a cure for cancer. The committee on finance has discontinued the annual appropriation of $15,000 to the Cancer Laboratory at Buffalo, as it was asserted that nothing could be shown in return for the money expended.

Pre-nuptial Examination.—A bill will be introduced in the New York legislature providing that all persons must obtain a physician's certificate before a marriage license can be obtained. The bill is intended to put a restriction on the marriage of imbeciles and also to prevent those having consumption and other diseases from marrying.

Toy Pistol and Tetanus.—In view of the agitation by the various medical societies of the state relative to the relation between tetanus and the toy pistol, Senator Armstrong has introduced a bill in the legislature providing that no loaded blank cartridges, toy or other pistols shall be sold to boys under eighteen years of age.

Typhoid at Poughkeepsie.—Within a few weeks so many cases of typhoid fever have developed in Poughkeepsie and the situation is considered so grave that it is feared the State Board of Health will have to be called in and vigorous measures taken to wipe out the disease. There are 21 cases now under treatment at Vassar Hospital.

State Water and Sewer Commission.—A bill is pending at Albany which has for its aim the state control of the water and sewage system of all towns within its boundaries. The board of management is to have power to plan new sewage and water plants and to provide for the extension and improvements of old plants, and to exercise legal control over all conditions detrimental to public health.

Supposed Smallpox, as Usual, Smallpox.—A large number of cases of supposed smallpox has existed in Owego for a number of weeks, but Dr. Lewis and other physicians asserted that it was chicken-pox, and have opposed quarantine. Dr. G. B. Lewis and another patient broke quarantine at Owego and came to Buffalo riding in the trolley cars of that city to consult a specialist in order to prove that they had chicken-pox. When the specialist saw them he immediately reported the cases as smallpox to the health department at Buffalo, and the health authorities and the police are looking for the patients.

The State's Insane.—The tent treatment for the tuberculous and untidy insane has been pronounced successful. There were 147 alien lunatics returned to Europe, and in addition 104 non-resident insane were sent out of the state during the year. More rigid inspection of immigrants at the various ports of entry is needed to insure against alien insane. The commission suggests boarding out old harmlessly demented persons in private families. Since 1903 emergency cases can be sent to state hospitals for prompt examination and report by qualified experts. The new statute provides for the retention of a patient received on such certificate in state hospitals for a period not to exceed 5 days pending the procurement of judicial approval of the medical certificate. This obviates delays by reason of the absence of judicial officers at the time the patient is sent to the state hospital. In this connection the commission recommends the establishment of a temporary detention hospital in New York City and of accommodation at the state hospital in large cities for emergency cases in place of jails and station houses.

Buffalo.

Personal.—Dr. Burt Johnson has gone to Jamaica.——Dr. Roswell Park has sailed for Europe and will return in May.——A complimentary dinner was tendered to Dr. John H. Pryor.

Insane Patient Attacks Physician.—While examining a woman as to her sanity Dr. Floyd S. Crigo was attacked by her with a knife and pursued into the street, barely escaping. Later she was overcome by the police and committed to the state hospital.

Deaths in February.—The monthly report of the department of health for February shows an annual death rate of 14.43 per 1,000. The principal causes of death were as follows: Consumption, 45; debility, 47; cancer, 20; meningitis, 16; apoplexy, 29; valvular disease of the heart, 33; pneumonia, 66; and violence, 23. The total deaths for February, 1904, were 457, as compared to 474 for February, 1903.

Eddyite-Treated Child Dies.—Health Commissioner Greene and District Attorney Coatsworth are investigating the death of William Dobbertin, 5 years of age. The child died of diphtheria, and it is stated that the only treatment given the child was by Eddyism. The boy was treated by two women healers, who gave absent treatment, and during the short illness no examination was made of the throat. A physician was called, but found the child dead and reported the case to the health authorities. Several months ago a somewhat similar case was called to the attention of the grand jury through the medium of the district attorney, but the grand jury reported "no bill."

New York City.

Measles in Greater New York.—Up to March 19 there were 1,435 acute cases of measles in the five boroughs; a number greater than that in any year since 1898.

Pneumonia.—Latest reports show a mortality of more than 6,000 since the first of last December. This is an increase of 31 per cent. over last winter. Next year it is expected that the board of health will treat pneumonia as an infectious disease.

Bill Favoring Rockefeller Institute.—Senator Dowling has presented a bill which prohibits the opening of any street through lands occupied by the Rockefeller Institute for Medical Research, between East 65th and 67th streets in New York City.

Jail Declared Unsanitary.—Sheriff Hesterberg of Kings County has been served with a five-day notice by the department of health to vacate Raymond Street Jail, Brooklyn, which repeatedly has been declared unsanitary and in a dangerous condition.

Bellevue Overcrowded.—For the first time in the history of Bellevue Hospital 1,000 patients were housed there on March 12. The hospital has accommodations for only 857 patients. Considerable apprehension is causced by this number in view of the financial difficulties of several other hospitals in the city.

Ward in Roosevelt Closed.—As the result of the lack of funds the woman's surgical ward in Roosevelt Hospital has been closed. This makes the third ward in large hospitals in this city which has been compelled to close for lack of funds. At least $500,000 is needed to put Roosevelt Hospital on a sure footing.

Scarlet Fever and Measles in Bronx.—The Bronx Board of Health reports over 400 cases of measles and 150 cases of scarlet fever, with a daily increase of between thirty and forty cases. The Roman Catholic Orphan Asylum at King's Bridge is suffering from the epidemic. Since February 10 31 cases of scarlet fever have developed among 800 inmates.

New Masonic Hospital.—The Masonic Hospital and Shelter Association of Brooklyn has been incorporated for the purpose of maintaining a place where Masons can get medical and surgical care. For this purpose the upper floors of the Eastern Homeopathic Dispensary have been rented. The hospital will be opened as soon as the necessary repairs have been made.

Mount Sinai Hospital Open.—The new Mount Sinai Hospital was dedicated March 16. About 10,000 invited guests visited the hospital during the day. The new hospital is built on the pavilion plan, except that its ten buildings are connected by their ground floor corridors. All reasonable provision has been made for the standing needs of progressive medical science and hospital administration.

Dirty Money.—Dr. Darlington, health officer of New York, reports as a result of his investigation that bacteria do not live longer than forty-eight hours on silver, nickel and copper coins. Two dirty bills were washed, one contained 135,000 bacteria, the other 126,000. Two comparatively new bills contained respectively 2,250 and 2,000 germs. On all were found staphylococci, proving that money may carry disease.

Personal.—Dr. Lewis A. Stimson's yacht is being fitted out for a cruise in the Mediterranean and in British waters.——Dr. William T. Bull has been reported ill; appendicitis was feared. ——The following new appointments have been made at Columbia University: Dr. Edwin B. Cragin, professor of gynecology; Dr. H. M. Painter, clinical professor of obstetrics; Dr. Gorham Bacon, professor of otology, and Dr. William Kelly Simpson, professor of laryngology.——Dr. Heinrich Stern has severed his connection with the New York School of Clinical Medicine.

Financial Aid for Eye and Ear Hospitals.—Both the Manhattan Eye and Ear Hospital and the New York Eye and Ear Infirmary have been very much embarrassed financially and there was much anxiety as to whether they would be able to continue their work, at least in its entirety, but at a recent meeting of the board of managers of the New York Eye and Ear Infirmary the trustees subscribed personally and succeeded in raising about $26,000 of the $30,000 required for the coming year. The officials of the Manhattan Eye and Ear Hospital declared at their meeting on March 18 that there was no possibility of their closing any of their wards, as they had an annual income of $50,000, but that they still needed an endowment fund of $250,000.

PENNSYLVANIA.

Philadelphia.

Reception to Dr. Heller.—A reception was given at the Bingham House in honor of Dr. Henry D. Heller, state quarantine physician. Dr. Heller was presented with a handsome model of the new state quarantine tug, *Governor Pennypacker*.

Quarantine Removed.—The quarantine of the Methodist Episcopal Hospital established some time since, as the result of one of the employes being infected with smallpox, has been lifted, and visitors are now admitted to the institution.

Physician Injured.—Dr. Christopher A. Frame, while on his way to visit a patient, was struck by a freight train on the Pennsylvania railroad and received a very severe laceration of the scalp and several contusions of the shoulders and back. His injuries, however, are not likely to prove fatal.

Leper Discovered.—A leper was discovered in the lower section of the city during the past week. He had been in the city about three weeks and applied to a physician for treatment of some skin affection. Diagnosis of leprosy was made. The patient is now in charge of Dr. Schamberg, and efforts are being made for his deportation to Hawaii, the place of his nativity.

Interneships at Blockley.—The examinations for resident internes in the Philadelphia Hospital will be held early in April. The number of appointments to be made are 19, and these will be made in strict accordance with the average attained in the civil service examinations. Heretofore, equal representation in all medical colleges on the staff of internes had been assured. Now the men are to be appointed absolutely in accordance with the average attained.

Maragliano Can Not Come.—A cablegram received from Professor Maragliano by the Henry Phipps Institute, under whose auspices he was to lecture March 28, announces his sickness and inability to come. An abstract of his paper will be read at a luncheon to be given Monday by Dr. L. F. Flick to the delegates to the meeting to consider the tuberculosis congress situation. The delegates will also be entertained at dinner Monday by the Henry Phipps Institute. (The meeting of this committee is mentioned on the next page.)

Health Report.—There has been little or no abatement of typhoid fever during the past week. This has not been looked for. In fact, a large increase in cases was expected owing to the bad condition of the drinking water during the past few weeks. During the last week 141 new cases were reported, which is one less than reported during the preceding seven days. There were 21 deaths from typhoid, a decrease of 4 from last week. Smallpox is on the decline, the whole number of cases reported being 30. This is 18 less than the previous week. There were 7 deaths from smallpox, an increase of one over the preceding week. The deaths from all causes numbered 634. This is a decrease of 75 from those of last week and an increase of 99 over the corresponding week of last year.

Symptoms of Contagious Diseases.—Dr. Jay F. Schamberg lectured to the principals and teachers of the public schools on "Symptoms of Smallpox, Scarlet Fever and Measles." He said that more than 3,000 cases of smallpox have been treated since 1900 at the Municipal Hospital. Of this number not one individual had been recently successfully vaccinated. Moreover, not one patient received had a good scar of vaccination. The patients admitted comprised two classes: Those never successfully vaccinated, and adults not vaccinated since infancy or childhood. These statements, he said, held good for more than 8,000 smallpox patients treated by Dr. Welch in the Municipal Hospital during the last 33 years. During the past three years 120 nurses have been employed at the hospital, and not one has been affected with the disease. He said there was greater danger to an individual walking on the streets of a large city than in being vaccinated. In this city, from 1901 to 1903, 665 persons died of smallpox. Every one of these lives could have been saved. The man who refuses to have his children vaccinated is guilty of criminal negligence. In conclusion, he advised that teachers and parents should heartily co-operate with the department of health in the matter of school inspection in its crusade against disease.

GENERAL.

HALF FARE TO ATLANTIC CITY.

[By Special Telegram.]

Trunk Lines Grant Low Rate, and Other Associations Expected to Follow.

As The Journal goes to press, a telegram is received with the following announcement:

The Trunk Line Association has just granted a half-rate fare to the next session of the American Medical Association, and recommends that all other passenger associations do likewise. This means a half rate from practically all over the country. It is the first time that the Trunk Line Association has done better than a one and one-third rate; it has refused until to-day to do better this year. This rate means doubling the attendance at the Atlantic City session.

Personal.—Dr. T. Aoyama, dean of the Japanese National Medical University of Tokio, a prominent surgeon of Japan, has been visiting the United States on his way home from a period of study in Berlin.

Porto Ricans Want Medical Officers on Steamers.—The Ponce branch of the Chamber of Commerce of Porto Rico protests against the monopoly which controls trade with the United States, and mentions the lack of medical officers on the steamers. They suggest that regulations be made compelling boats engaged in passenger traffic to carry medical officers and necessary medicines and appliances.

Tuberculosis Congresses.—Dr. William Osler, chairman, and Dr. Henry B. Jacobs, secretary, announce that at a meeting of the tuberculosis committee (appointed at the Baltimore Exhibition), held in New York, February 27, it was decided to refer to a larger gathering the discussion of the question relating to organizations for the study of tuberculosis in this country. A meeting will be held for this purpose at the College of Physicians, 13th and Locust streets, Philadelphia, March 28, at 3:30 p. m.

October Health in Philippine Islands.—The rate of mortality in the Philippine Islands during October last was five times greater among the Filipinos, and nearly two and one-half times greater among the Chinese than among the combined American, Spanish and other European population. The poverty of the poorer classes is partially responsible for this. The authorities are endeavoring to secure better sanitary conditions and to prevent overcrowding. Of the total 1,279 deaths, 654, or 51.8 per cent., occurred within the first year of life. Eliminating cholera, which did not affect infants under one year, the infant mortality was 57.3 per cent. of the total. To reduce this infant mortality popular circulars, giving rules for the care of the newborn and for the feeding of infants, are being distributed. The more important causes of deaths were as follows: Infantile convulsions, 383; pulmonary tuberculosis, 110; cholera, 104; eclampsia, non-puerperal, 72; bronchitis, 117; diarrhea and enteritis, 56; congenital debility, 35; typhoid fever, 14. Pneumonia caused 5 deaths, bubonic plague, 2. The campaign of inspection and of extermination of rats to prevent plague is being carried on vigorously. A portable steam and formaldehyd disinfecting chamber, mounted on trucks, was ordered.

CANADA.

Vaccination in Montreal Schools.—The Montreal Health Department's report of school vaccinations shows that this season few scholars refused to undergo vaccination. In all 20,736 vaccinations were performed, there being absent from the schools 721 when the vaccinators called.

A Consumption Sanitarium for Hamilton, Ont.—At a public meeting at Hamilton, Ont., March 15, it was decided to organize a branch of the National Sanitarium Association. The medical health officer of Hamilton, Dr. Langrill, favored erecting a sanitarium on the brow of Hamilton mountain.

Deaths in Ontario for January.—The Ontario deaths in January were 2,188, or at the rate of 13 per 1,000, as against 2,150 in January, 1903, when the rate was 12.8. There were 102 cases of smallpox, as against 196 a year ago. Scarlet fever cases numbered 379 as against 500 in January, 1903. The deaths from contagious diseases were: Scarlet fever, 24; diphtheria, 59; measles, 2; whooping cough, 7; typhoid, 23; tuberculosis, 187.

Hamilton Hospital Rates.—The rates in the public wards of Hamilton General Hospital will be lowered from $3 to $2.80 per week. The difference, it is expected, will be more than made up by the additional government grant of 20 cents per day, for all patients paying under $6 per week. Private ward patients will hereafter pay $4.20 and $7 per week, instead of $4 and $6 per week. These changes will considerably increase the hospital's revenue. There is now considerable erysipelas in this hospital.

Furnishing the Toronto Free Consumption Hospital.—A meeting was held last week to make preparation for furnishing the Toronto Free Hospital for Consumptives, situated ten miles beyond the city limits. It was announced at this meeting that a site near the University of Toronto medical buildings had been secured for a dispensary building, from which free medicines will be dispensed for consumptives. A staff of nurses will also be maintained. The reports submitted showed that the National Sanitarium Association has thus far expended upward of $400,000 on this work in Ontario, of which $180,000 had gone into the building fund. Altogether 1,000 patients have been treated, and of 32 consumptives who were cured five years ago, 31 are now living. A large committee was formed to raise funds for the Toronto institution. The hospital is to be used for persons in the advanced stage.

FOREIGN.

Plague in Africa.—Bubonic plague has broken out in the Indian coolie district of Johannesburg, South Africa. Forty-two deaths have occurred.

Japanese Aid Virchow Memorial.—Four hundred dollars were recently received from Japanese physicians as a contribution to the fund to erect a memorial to Virchow at the Charité, Berlin.

Money for Medical Colleges.—Sir Donald Currie, one of the pioneers in the opening up of South Africa, has given $500,000 to the University College Hospital, London, Eng., for new medical buildings.

Anti-alcohol Colony in Italy.—The *Riforma Medica* announces that an English capitalist, named Charrington, has purchased an island off the coast of Italy to found thereon an anti-alcoholic colony.

Radium Treatment of Cancer Abandoned.—It is announced that the use of radium for the treatment of cancer has been discontinued at the London Cancer Hospital, and that attention will now be devoted instead to the use of high frequency apparatus. Radium did not seem to be of benefit.

Prize for Elimination of Intoxicating Properties of Alcohol.—The Russian minister of finance offered, just before the outbreak of the war, a prize of $25,500 for the discovery of a "denaturating" substance for alcohol which leaves no mineral residuum, does not contain caustic or poisonous elements and does not impart a repellent odor.

Second Latin-American Medical Congress.—April 3 to 10, 1904, is the date appointed for the opening of the Latin-American Congress of Medicine and Hygiene to be held at Buenos Ayres, Argentina. The exposition connected therewith is to remain open through April and May. It has been planned on an extensive scale.

"Consul" is Dead.—The trained chimpanzee, "Consul," valued at $125,000, succumbed recently to an acute lung affection at Berlin. He put up at good hotels and always had a room to himself, with engagements booked for two years in advance at a monthly salary of $4,000, and his life was insured for

$100,000. The *Gazette Méd. de Paris* has devoted considerable space during the last few months to descriptions of this almost human creature.

Children Summoned to Inspect Mad Dog.—A veterinary surgeon in a French town having a mad dog under observation sent for the children of the schools to come and inspect it. He did this to combat the general idea that a dog is not mad unless he is foaming at the mouth, etc. The children found this animal lying quietly in its cage, its mouth and tongue merely parched and feverish, and yet it was known to be a typical case of rabies.

Scotch Generosity.—The *Riforma Medica* states that the ophthalmologist, Prof. T. Reid of Glasgow, has presented $29,100 to the ophthalmic clinic at Turin, in charge of Professor Reymond, for the advancement of science, to aid in purchasing instruments and in paying the salaries of the officials connected with the clinic. His friendship for Professor Reymond is the motive for the endowment, and during his lifetime he is to receive an annual 3 per cent. interest on the sum.

Memorial to Hanot.—The *Archives Générales de Médecine* has opened a subscription to erect a memorial to its former editor, professor agrégé, V. Hanot, whose tragic death in 1896 will be remembered. The bust or tablet will be erected at the scene of his labors in the Saint-Antoine Hospital, Paris. The committee in charge ask for the names of friends and pupils of Hanot who might like to co-operate in this tribute. Address Hotel des Sociétés Savantes, 28 rue Serpente, Paris, France.

Suit for Return of Fees.—The professor of gynecology and obstetrics at the Russian university of Dorpat maintains a private hospital at Odessa. He received a wealthy patient into his hospital for an operation, and a fee of $102 was paid in advance. The patient died almost at once after the operation, and the family sued for the return of the money. Professor Solovieff declined to return it, saying that he had been to great expense in preparing for the operation. The local court has ordered him to return one-half the amount.

Battle of the Clubs in Italy.—At Biella, upper Italy, the medical officers of a mutual aid society were remunerated at the rate of four cents a visit, and not only forfeited this amount if they did not arrive at the bedside within half an hour of the summons, day or night, but were obliged to pay the fee of another physician summoned in their place if they failed to respond promptly. This state of affairs having proved unbearable, they have resigned and the other members of the profession are standing by them in refusing to accept positions in the society. One Italian exchange has coined the term "boycottaggio," whose origin is obvious, to express this concerted action on the part of the profession.

Proposed Hospital for Temporary Disability.—Babinski of Paris suggests the foundation of a hospital for semi-invalids, that is, for persons who are unable at times to work on account of temporary disability from exacerbation of some latent chronic affection. This asylum should also be open to such infirm persons for temporary shelter outside of exacerbations, if they find it impossible to obtain work. The shelter and the food provided should not be of such a character as would tempt them to linger in the asylum when they can do better outside. The inmates should only be admitted on presentation of a card given to them after a thorough medical examination. This intermediate station between the night shelters and the hospitals would relieve the latter of much trouble and expense, while it would prove a boon to many of these semi-invalids. It would also serve to eliminate the frauds.

The Russian Red Cross Society.—A French exchange states that the Russian Red Cross Society was founded in 1860 at Moscow, and now has more than 600 organized committees, 42 hospitals, 2 training schools for nurses, 8 soldiers' homes, one home for widows, 4 for orphans of soldiers and 2 sanatoria for children. There are more than 4,000 women nurses and a battalion of men nurses. Our Russian exchanges have contained of late many notices of the way in which relief work for the war has been systematically proceeding. The Red Cross supplies at Charbin now include nearly $40,000 worth of materials for dressings; they have medical supplies for 30,000 beds. Beside this, 26 field hospitals have been set up with 5,050 beds. To each 500 beds there are 5 physicians, one administrator, 15 women nurses, and 30 other attendants. Six of these have already been installed at Charbin. The society is being constantly and lavishly supplied with gifts of linen, preserves, wines and other delicacies with contributions of money. Holland is preparing a field hospital, and another is being equipped by Russians resident at Berlin, which will soon start for the seat of war.

Isolation of Consumptives in Paris Hospitals.—Sweeping changes are contemplated by the executive committee in charge of the Paris hospitals in order to conform to the ministerial decree in regard to the strict isolation of consumptives (mentioned in an editorial last week under the heading of "Tuberculophobia"). It is proposed to transform four of the hospitals, the Laennec, Hotel Dieu annex, Broussais and Bastion 27, into specials to receive tuberculous subjects only. This will supply 1,184 beds, with 909 additional in special pavilions in four other hospitals and 1,850 in four others, either extramural or in process of construction. There will thus be a total of 3,776 beds for subjects with pulmonary tuberculosis. They will be supplemented by 2 special dispensaries for tuberculosis in connection with the Laennec and Tenon hospitals. The scheme requires the suppression of twenty-two medical services, two surgical and one obstetric, and a radical revolution in several other respects. The local medical press does not regard the project with much favor, but is loyal in its support of the laudable intentions which have inspired the agitation of the subject. The suggestion to isolate the cases of "open tuberculosis" in a ward by walling off one end of the ward with glass partitions was offered by the Société Médicale des Hôpitaux as a simple and practical solution of the question, as mentioned in these columns, February 13. It has not been considered by the authorities as sufficiently radical.

Destruction of Rats in France.—The ravages caused by the field rats in agricultural districts of France have caused the government to take up the matter. A bill has been submitted by the government to the chamber of deputies providing for the issue of bonds to raise $70,000 to be applied to the destruction of field rats. Experiments have recently been made on a large scale in la Charente where a large tract of land—about 3,000 acres—was honeycombed with rat holes. The work was in charge of Danysz and Chamberland of the Pasteur Institute. Cultures of the bacillus which Danysz has found is pathogenic for field rats were spread on bread or oats and distributed in and near the rat holes. Over 10,000 pounds of bread and twice this amount of oats and 1,200 bottles of the virus were used. The results showed that 95 per cent. of the rats had been destroyed. The campaign progressed without mishap and no domestic animals were injured. It is unfortunate that no virus has yet been discovered effectual against the town rat, which is much more resistant. Roux believes that the prospects are bright for this achievement in the near future. The legislation now in progress contemplates that the land owners must pay a certain proportion of the expense of the anti-rat campaign. Rats are not only concerned in the transmission of the plague, but also of trichinosis. Certain epizootics are likewise due to them, as they transmit the germ, although they do not contract the disease. The Danysz cultures are perfectly harmless for persons handling them and for domestic animals.

LONDON LETTER.

The Middlesex Hospital and Cancer Research.

The Middlesex Hospital alone among the general hospitals of London devotes and reserves a number of its beds for the reception of the metropolis cases of cancer and lately has established a cancer research laboratory, which is under the direction of Dr. Lazarus Barlow. During the past year 100 cases of cancer have been treated with 3,040 applications of the *x*-rays, with results decidedly encouraging. In the large majority pain was diminished, if not dissipated, in a considerable number the disease was retarded, and in a few it underwent marked retrogressive changes. Radium has been tried, and several cases of lupus and rodent ulcer have healed more rapidly under it than under the *x*-rays or violet light. One branch of work for which the laboratory staff is responsible is the testing of the many alleged cancer cures brought forward from time to time. A considerable amount of time is thus spent without any corresponding advantage. Recently attention was widely drawn to the successful results alleged to have been obtained from Dr. Otto Schmidt's serum treatment. At the Abernethian Society of St. Bartholomew Hospital a physician who had been to Cologne and studied under Dr. Schmidt reported most gratifying results. His paper and the discussion which followed occupied more than five pages of the *Lancet*, and that journal devoted a lengthy editorial to it, though regarding its value as unproved. The experience of the Middlesex Hospital relegates this remedy to the place of all cancer cures. Nine patients voluntarily submitted to the injections. All that could be said of the specific was that it did no harm.

Correspondence.

"English Bards and Scotch Reviewers."

Philadelphia, March 17, 1904.

To the Editor:—In The Journal March 12, you "review" "Biographic Clinics," Vol. II. If you had taken the ordinary precaution of reading the volume doubtless you would have avoided the many misstatements, misquotations, and inaccuracies which destroy any possible value of your article as criticism. The volume will scarcely come into the hands of all the readers of The Journal, and fair play demands that, in the interests of impartial and dispassionate criticism, some, at least, of these misstatements and misquotations be pointed out.

1. You repeatedly speak of "the fourteen patients" whose cases are considered in the volume. There are but nine.

2. I did not "guess" that Parkman had ametropia; I demonstrated it by the prescriptions of his oculist.

3. You say that I include cancer as one of the diseases caused by eyestrain. There is not a line in the book authorizing this statement.

4. You aver that I refrain from telling what proportion of symptoms mentioned is caused by eyestrain. This is untrue.

5. In quotation marks you speak of some writing of mine called, "Why glasses did not fit." The phrase is unworthy the knowledge of even a first-year medical student. No essay of mine with such a title exists.

Your *review* is *proved incompetent and* your "*criticism*" worthless because:

A. You do not even mention the great contention of the volume—the demonstrated production of morbid symptoms by reading and writing and the immediate relief by stopping this near use of the eyes.

B. You do not even allude to the proofs that migraine may be the result of eyestrain: (*a*) the testimonies of public patients; (*b*) the testimonies of many American oculists; (*c*) my own testimony of the large number of patients I have cured by glasses alone.

C. You ridicule the work and assertions of "*diligent and energetic ophthalmologists*" and gibe at their emphasis of the reflex results of eyestrain, ignoring the fact that the oculists who believe in these results have, in comparison with The Journal and the reviewer, the better right to their opinion which comes from affirmative experience. It requires little knowledge, less experience, and no intellect, to echo musty traditions and "accepted views," but advancement comes not by that path.

D. You fail to name any of the "innumerable," the "uncountable," the "thousand," the "all," articles, papers, reprints, text-books, in which have appeared this theory as to eyestrain which you alternately deride as a "new doctrine" and announce as having been "persistently preached in medical journals any day these twenty years." My knowledge of ophthalmologic literature should, presumably, be at least as great as yours, but I would greatly appreciate the naming of but one poor hundred among the thousands to which you negligently allude.

E. You have not demonstrated your right to lecture the specialist on "the narrowing effect of his specialty" by proof of your own wide knowledge of medicine in all its directions and history, nor by the slightest evidence of unbiased judgment. This is particularly necessary in one who measures knowledge by negation instead of affirmation. Geo. M. Gould.

[1. There were, in all, fourteen important personages mentioned in volume II. whose symptoms were assumed to depend almost entirely on eyestrain; nine of these were considered at length in this volume. The ill health of the other five had been considered at greater length in a previous volume. In volume II. Dr. Gould frequently refers, as we did, to these fourteen.

2. Dr. Gould was not accused of "guessing" that Parkman had ametropia; it *was*, however, asserted that our "guess" (that the historian suffered from an asthenopia aggravated by or mostly due to neurasthenia) was quite as near the truth (or as far removed from it) as the author's, viz.: that his years of ill health were due to eyestrain curable by glasses.

3. We apologize to Dr. Gould for including cancer in the *catalogue of evils* (rheumatism, erysipelas, suicide, etc.), mentioned by him as the possible results of eyestrain. As he had mentioned cancer a few lines before and as it seemed to us quite as probable that eyestrain *might* produce rheumatic arthritis as this malignant neoplasm, we thoughtlessly added it.

4. If so we have searched his book in vain.

5. The exact title is "Sixty-eight reasons why 'glasses did not give relief.'"

A. We do not accept the statement that a patient's symptoms are inevitably due to eyestrain (curable by glasses) because some or even all of them are relieved by cessation from *near work* or because they are again brought on by renewed employment of the eyes. Everybody knows that many other conditions—neurasthenia, diseases of lids, heterophoria, lesions of the interior of the eye, etc.—may prevent the comfortable use of the visual organs. We have already insisted on that in some fourteen lines of fine print—one for each *patient.*

B. We have nowhere denied that now and then migraine is of ocular origin. We placed the proportion of cases curable by spectacles at less than 10 per cent. and declared that ophthalmologists and neurologists generally agree with us and not with Dr. Gould, who says (page 123, Vol. II.), "I have had thousands of patients with this disease (migraine) and 99 out of every 100 were cured by spectacles."

C. It was far from our intention to ridicule the belief in the reality of eyestrain and its consequence. We plead, however, for a saner view of the situation than that taken by Dr. Gould, who, in our judgment, greatly exaggerates the rôle of this factor in producing disease.

D. We stated that the "main facts of ametropic and heterophoric viciousness" have been published broadcast throughout this and other lands for many years and, in our opinion, have long been known, especially to the members of the medical profession in America. The demand for a "poor hundred" articles on the subject could (had we the space for them) easily be met by selections from the ophthalmic literature of the past few years—a period when the subject has become so utterly commonplace that few observers consider it worth their while to write on it.—Ed.]

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

CHARGES FOR SERVICES TO PHYSICIANS AND THEIR FAMILIES.

Tennessee, March 11, 1904.

To the Editor:—Please answer, without using my name, the following: A physician is called on to attend a confinement. The woman's husband attended a medical college last year in his senior year, and applied for graduation, but failed to graduate. He was engaged at the time, and continuously since, in an occupation in no way connected with the practice or study of medicine. It is probable that, after legitimate professional expenses are deducted, his salary is equal to or exceeds the income of the physician who attended his wife. The physician remained with the woman from early morning until dark of one day, losing the entire day. The physician is employed for several hours each day in public health work at a per diem salary which is lost on the day referred to. Will you express an opinion as to (1) whether or not a fee ought to be charged; (2) is there anything in the *Principles of Ethics* to cover such cases? ——— L.

Answer.—1. Yes. 2. Yes. The Principles of Ethics say that gratuitous services should be limited to practicing physicians, their immediate family dependents, persons in indigent circumstances and certain public duties (sanitation and public hygiene).

CAISSON DISEASE.

Detroit, March 19, 1904.

To the Editor:—1. Can you tell me how I can get in touch with any available literature which treats of the pathology and treatment of diseases which are common to workmen in compressed air? 2. Do you know who publishes "Articles by Paul Bert" on the subject of compressed air? E. E. BRATTON.

ANSWER.—1. In Oliver's "Dangerous Trades" (E. P. Dutton & *Co., New York City*, $8), pages 728 to 737 discuss the subject. Most text-books on the practice of medicine give some space to it. A long list of references is given in the Index Catalogue of the library of the Surgeon General's office. You might address one of those mentioned in THE JOURNAL, Dec. 19, 1903, page 1553. 2. No. These appeared about thirty years ago.

SMALLPOX AND CHICKEN-POX.

ALABAMA, March 13, 1904.

To the Editor:—1. Is it possible for the eruption of varicella to so simulate variola as to invade the palms of the hands? 2. Is it possible for a patient to have variola without pains in the head, back or legs or other symptoms other than slight fever and eruption? 3. Give full differential diagnosis between smallpox (variola) and chicken-pox (varicella). SUBSCRIBER.

ANSWER.—1. Yes. 2. Yes. 3. We must refer you to any good text-book for this information.

STATES REQUIRING LICENSES TO PRACTICE.

NORTH CAROLINA, March 18, 1904.

To the Editor:—Please send me a list of all the states that do not require a license to practice medicine D. S.

ANSWER.—All states and territories except Alaska require licenses.

Marriages.

JACOB L. ALBRIGHT, M.D., to Miss H. Mabel Evans, both of Chicago, March 9.

DAVID SALINGER, M.D., Chicago, to Miss Amalie Frisch, at Baltimore, March 7.

NEVIN D. PONTIUS, M.D., Seattle, Wash., to Miss Edith B. Cole of San Francisco, March 2.

FRANK T. SIMONTON, M.D., Ellsworth, Maine, to Miss Marion Thayer of Charleston, Maine, March 8.

JOHN J. HANNA, M.D., Victoria, Texas, to Miss Georgiana Houser of Lincoln, Ill., at New Orleans, March 11.

Deaths.

William H. Hawkes, M.D. University of Pennsylvania, Philadelphia, 1874, a member of the American Medical Association; professor of materia medica and therapeutics, Georgetown University; member of the American Academy of Medicine, Medical Association of the District of Columbia, Medical Society of the District of Columbia; attending physician, Emergency Hospital; consulting physician, Providence Hospital; at one time assistant surgeon in the Army, died at his home in Washington, D. C., March 13, from acute gastritis, after an illness of two hours, aged 58.

William Frederick Holcombe, M.D. Albany (N. Y.) Medical College, 1850, of New York City, at one time professor of diseases of the eye and ear in New York University Medical College, New York Ophthalmic College and Hospital, and New York Medical College for Women; one of the founders of the New York Genealogical and Biographical Society and a member of the International Medical Congress, died in the Presbyterian Hospital, New York, March 17, after a short illness, aged 76.

Moreau Morris, M.D. College of Physicians and Surgeons, New York, 1848, a member of the American Public Health Association, health commissioner in 1866, and special medical inspector to all institutions for children; for thirteen years surgeon of the Seventh Regiment, N. G., N. Y., and later of the Seventh Veterans' Association, died at his home in New York City, March 17, aged 78.

Julius J. Kempe, M.D. Albany (N. Y.) Medical College, 1868, a member of the American Medical Association, for more than thirty years an esteemed practitioner of Rochester, N. Y.; a member of the Rochester City Hospital staff, and of the Monroe County Medical Society, who moved to Florida on account of ill health, in June, 1903, died at Pinellas, Fla., March 7, aged 60.

Dan Peaslee Webster, M.D. University of Vermont, Burlington, 1867, some-time postmaster of Brattleboro, member of the legislature from Putney in 1872 and 1874, and senator from Windham County in 1878, surgeon general of Vermont for two administrations, died at his home in Brattleboro, Vt., March 13, from Bright's disease, after a long illness, aged 57.

Hans Herman Behr, M.D. University of Berlin, Germany, 1843, scientist, entomologist and savant; who was given the degree of doctor "Honoris Causa," by his alma mater in 1898; vice-president and curator of the San Francisco Academy of Sciences in 1864, died at his home in San Francisco, March 13, aged 85.

John P. Edge, M.D. Jefferson Medical College, Philadelphia, 1846, a member of the state legislature from 1875 to 1878; originator of the bill establishing the State Board of Agriculture; a member of the county and state medical societies, died at his home in Downingtown, Pa., March 7, aged 81.

M. Thomas Brennan, M.D. Laval University, Quebec, 1884, professor in Laval University, gynecologist to Notre Dame Hospital, Montreal, a member of the Fourteenth International Medical Congress, died at his home in Montreal, March 12, from pneumonia following influenza, aged 42.

William Henry Seton, M.D. University of Maryland, Baltimore, 1898, a member of the American Medical Association, formerly of New York City, who went to Arizona on account of ill health two years ago, died at his home in Phoenix, February 11, from spinal meningitis, aged 31.

Leander Swartwout, M.D. Albany (N. Y.) Medical College, 1880, a veteran of the Civil War; member and some-time president of the Oneida County and New York State medical societies; once coroner of the county, died at his home in Prospect, N. Y., March 11, aged 61.

Spottswood Wellford Carmichael, M.D. Jefferson Medical College, Philadelphia, 1852, the third in direct line of his profession in the same town; a surgeon in the Confederate service, died at his home in Fredericksburg, Va., March 18, after an illness of one year, aged 73.

William Gulick, M.D. College of Physicians and Surgeons of the Western District of New York, Fairfield, 1837, formerly assemblyman, and once president of the State Board of Health, died at his home in Watkins, N. Y., March 16, from pneumonia, aged 90.

James S. McCorkle, M.D. University of Nashville, 1860, repeatedly mayor and recorder of Newbern, and for 25 years president of the local board of education, a confederate veteran, died at his home in Newbern, Tenn., from influenza, March 11, aged 66.

R. Edgar Zackery, University of North Carolina, Chapel Hill, 1897, M.D. North Carolina, 1898, of Wilmington, N. C., died at the James Walker Memorial Hospital in that city, from peritonitis, after an operation for appendicitis, March 12, aged 28.

Nathaniel T. Palmer, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1842, one of the founders of the Maine Medical Association, who had practiced in Brunswick for 59 years, died at his home in that city, March 18, aged 87.

James Brownlee Sanford, M.D. Baltimore University, 1900, a member of the American Medical Association, and speaker of the Colorado House of Representatives, died at his home in Denver, March 16, from appendicitis, aged 35.

W. B. Fewell, M.D. Medical College of the State of South Carolina, Charleston, 1850, died at his home, Ebenezer, near Rock Hill, S. C., March 7, from gastritis, after an illness of two or three months, aged 76.

John Marion Watkins, M.D. Tulane University, New Orleans, 1871, a member of the American Medical Association, who had been in ill health for several years, died at his home in Opelika, Ala., March 12, aged 60.

Thomas E. Moore, M.D. Transylvania University, Lexington, Ky., 1841, died at his home in Bolivar, Tenn., where he had practiced for more than 60 years, March 10, after a long illness, aged 86.

C. E. Bernhard, M.D. Kansas City (Mo.) Medical College, 1884, of Visalia, Cal., died at his home, Deer Creek, Hot Springs, Cal., March 9, from pneumonia, after an illness of one week, aged 47.

John B. Harmon, M.D. University of Pennsylvania, Philadelphia, 1886, formerly of Pueblo, Colo., died from pneumonia at Waterloo, Iowa, March 15, after an illness of four days, aged 38.

James M. Duncan, M.D. Missouri Medical College, St. Louis, 1876, died at his home in Kansas City, Mo., March 11, aged 65.

Henry S. Farnsworth, M.D. University of Vermont, Burlington, 1860, died at his home in Clinton, Iowa, March 17, aged 71.

Azariah Judson, M.D. Berkshire Medical College, Pittsfield, Mass., 1845, died at his home in Athens, Pa., March 3, from paralysis, after an illness of several months, aged 82.

Henry Newell Small, M.D. Hahnemann Medical College, Chicago, 1866, died at his home in Chicago, March 15, from cerebral hemorrhage, after an illness of two days, aged 62.

John Edward Janney, M.D. University of Virginia, Charlottesville, 1874, died at his home in Winchester, Va., March 20, from chloroform accidentally self-administered.

Henry B. Eddy, M.D. Ohio Medical University, Columbus, 1900, died at his home, Shadyside, Bellaire, Ohio, March 16, from consumption, after an illness of one year.

James S. Whitaker, M.D. Jefferson Medical College, Philadelphia, 1879, died recently at his home in Cherry Hill, Md., from neuralgia of the heart, aged 56.

Middleton Stuart Hanckel, M.D. Medical College of the State of South Carolina, Charleston, died at his home in New York City, March 12, aged 75.

Robert H. Wyche, M.D., who retired from practice 35 years ago, died at his home in Cool Springs Township, Iredell County, N. C., March 6, aged 80.

Philander S. Brewster, M.D. Pennsylvania, died at his home in West Berwick, Pa., March 5, from paralysis, after an illness of two years, aged 73.

William F. Coates, M.D. Tulane University, New Orleans, 1856, died at his home in Wills Point, Texas, March 13, after a prolonged illness.

J. Henry Robinson, M.D. Albany (N. Y.) Medical College, 1856, died recently at his home in Southboro, Mass., and was buried March 14.

Endymion S. Brown, M.D. Cleveland Medical College, 1869, died at his home in Newark, Ohio, March 12, after a long illness, aged 74.

Warren T. Dameron, M.D. University of Louisville, 1849, of Lexington, Mo., died in La Junta, Colo., from paralysis, March 6, aged 83.

William G. Carter, M.D. Harvard University Medical School, Boston, 1869, died at his home in Concord, N. H., March 10.

James Sanford, M.D. Jefferson Medical College, Philadelphia, 1857, died recently at his home in Collierstown, Va., aged 74.

George H. Neal, M.D. Hahnemann Medical College, Chicago, 1881, died at his home in Falls City, Neb., March 15.

Newton H. Curtiss, M.D. Syracuse (N. Y.) University, 1878, died recently at his home in Manlius, N. Y.

J. George Battell, M.D. Trinity Medical College, Toronto, 1895, of East St. Louis, Ill., died March 10.

Josiah B. Fox, M.D. Ohio, died at his home in Cleveland, March 10, aged 68.

Deaths Abroad.

A. Spiess, M.D., editor of the German quarterly for public health, and noted for his numerous works on matters affecting the public health, died at Frankfurt, February 1, aged 71.

J. J. Flores, M.D., formerly minister of the interior in the Republic of Costa Rica, and dean of the faculty of medicine at San José, died there February 2.

State Boards of Registration.

COMING EXAMINATIONS.

Regular Board of Medical Examiners for Georgia, Atlanta, March 30; Augusta, April 2. Secretary, I. H. Goss, M.D., Athens.

Arizona Board of Medical Examiners, Phoenix, April 4. Secretary, Wm. Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, Salt Lake City, April 4. Secretary, R. W. Fisher, M.D., Salt Lake City.

Board of Medical Examiners of Montana, Helena, April 5. Secretary, Wm. C. Riddell, M.D., Helena.

North Dakota State Board of Medical Examiners, Grand Forks, April 5. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of California, City Hall, San Francisco, April 5. Secretary, Geo. G. Gere, San Francisco.

Idaho State Board of Medical Examiners, Boise, April 6. Secretary, R. L. Nourse, M.D., Hailey.

Minnesota State Board of Medical Examiners, State Capitol Building, St. Paul, April 5-7. Secretary, C. J. Ringnell, M.D., Minneapolis.

Tennessee State Board of Medical Examiners, Memphis, Nashville and Knoxville, April 6-7. Secretary, T. J. Happell, M.D., Trenton.

Illinois State Board of Health, Chicago, April 6-8; April 25-27, and East St. Louis, May 4-6. Secretary, J. A. Egan, Springfield.

Rhode Island State Board of Health, State House, Providence, April 7-8. Secretary, Gardner T. Swarts, M.D., Providence.

State Medical Board of the Arkansas Medical Society, Little Rock, April 12. Secretary, J. P. Runyan, M.D., Little Rock.

Missouri State Board of Health, Kansas City, April 12-14. Secretary, W. F. Morrow, M.D., Kansas City.

West Virginia State Board of Health, Clarksburg, April 12-14. Secretary, Hugh A. Barbee, M.D., Point Pleasant.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Rutland, April 13-14. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, April 14. Secretary, Wm. C. Woodward, M.D.

Board of Medical Examiners for the State of Texas, Austin, April 21-23. Secretary, M. M. Smith, M.D., Austin.

State Board of Medical Examiners of Iowa, April 14-15 at Keokuk, April 20-21 at Des Moines. Secretary, J. F. Kennedy, M.D., Des Moines.

Arkansas Report.—Dr. J. P. Runyan, secretary of the State Medical Board of the Arkansas Medical Society, reports that at the written examination held at Little Rock, Jan. 12, 1904, 70 questions were asked on 7 subjects, and a percentage of 60 was required. Of the 14 who were examined 11 passed and 3 failed; 4 who passed and 2 who failed were graduates, the rest were not graduates.

PASSED.

College.	Year Grad.	Per Cent.
Kansas City Medical College	(1880)	75
Vanderbilt University	(1903)	83
Indiana Physiomedical College	(1900)	64
University of Pennsylvania	(1898)	85

FAILED.

College.	Year Grad.	Per Cent.
Arkansas University		57
University of Louisville		55

Oklahoma Report.—Dr. E. E. Cowdrick, secretary of the Oklahoma Board of Health, reports that at the written examination held at Enid, Dec. 29, 1903, 90 questions were asked on 9 subjects, and a percentage of 66 2/3 in each branch was required. Of the 10 applicants 5 failed, one not being a graduate. Those who passed were from the following colleges:

College.	Year Grad.	Per Cent.
Louisville Medical College	(1887)	84
Georgetown University	(1901)	85
University of Victoria College, Toronto, Canada	(1882)	85
Chicago Homeopathic Medical College	(1897)	83
St. Louis College of Physicians and Surgeons	(1900)	83

The four graduates who failed were from Ky. School of Med., 1876; Bennett Med. Coll., 1887; Keokuk Coll. P. and S., 1898, and Barnes Med. Coll., 1896.

Ohio December Report.—Dr. Frank Winders, secretary of the Board of Medical Registration and Examination of Ohio, reports the written examination held at Columbus, Dec. 8-10, 1903. The percentage required to pass was 75, and 90 questions were asked on 9 subjects; 31 were examined, 28 passed and 3 failed. Those who were graduates were as follows:

PASSED.

College.	Year Grad.	Per Cent.
University of Michigan	(1901) 93, (1902)	83, 91

The Public Service.

Navy Changes.

Changes in the medical corps of the Navy, week ending March 19, 1904:

Ferebee, N. M., medical director, detached from the Navy Yard, Washington, D. C., and granted sick leave for six months.

Peck, A. E., asst.-surgeon, granted sick leave for two months.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service, for the fourteen days ended March 17, 1904

Weitenbaker, C P surgeon, to report at Washington, D C, for special temporary duty.

Wickes, H V, P. A surgeon, granted leave of absence for one day

Von Ezdorf, R H, P A surgeon, to proceed to Delaware Breakwater Quarantine for special temporary duty Relieved from special temporary duty at Delaware Breakwater Quarantine on account of sickness and directed to rejoin his station at the Hygienic Laboratory, Washington, D C

Boggess, J S, asst surgeon, Bureau letter of March 2, granting eight days' leave of absence from Feb 18, 1904, amended so that said leave shall be on account of sickness

Simonson, G T, A A surgeon, granted leave of absence for five days from March 15

Staton, L W, A A surgeon, granted leave of absence for two days from March 3

Carter, H R, surgeon, to proceed to New Orleans and attend conference of quarantine officers March 14

Brooks, S D, surgeon, Department letter granting leave of absence for four months from April 1, 1904, amended to read four months from April 6, 1904

Guiteras, G M, surgeon, Department letter granting leave of absence for three months from Dec. 19, 1903, amended to read two months and five days from Dec. 19, 1903

McMullen, John, P. A surgeon, to proceed to Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty

Grubbs, S B, P A surgeon, granted leave of absence for twelve days from March 18

Richardson, T F., asst-surgeon, relieved from duty at New Orleans and directed to proceed to Laredo, Texas, and assume command of service at that port March 16

Francis, Edward, asst surgeon, to proceed to Delaware Breakwater Quarantine and assume temporary charge of station during illness of P. A. Surgeon C. H Lavinder March 10

Bullard, J. T, A A surgeon, granted leave of absence for twenty seven days from March 4

Moncure, J A, A. A surgeon, granted leave of absence for thirty days from April 1.

Nall, R P, A. A. surgeon, granted leave of absence for seven days from March 1, under Paragraph 210 of the Regulations

Sibree, H C., A A. surgeon, granted leave of absence for five days from March 15

Simonson, G T, A A surgeon, Bureau letter of March 10, granting leave of absence for five days from March 15, amended to read five days from March 22

Stanton, J G, A A. surgeon, granted leave of absence for thirty days from March 8

Thurston, E J, pharmacist, granted leave of absence for seven days from March 9, under Paragraph 191 of the Regulations

Kolb, W. W., pharmacist, granted leave of absence for twenty-eight days from April 2

APPOINTMENT

Dr Melvin M Hopkins appointed A A surgeon for duty at Ketchikan, Alaska

BOARDS CONVENED

Boards convened March 21 as follows for the physical examination of officers of the Revenue Cutter Service.

At New Orleans · Detail of the board Surgeon C P Weitenbaker, chairman, P A Surgeon L L Lumsden, recorder

At San Francisco Detail for the board P A. Surgeon W. G Stimpson, chairman, Asst surgeon Carl Ramus, recorder

At Port Townsend, Wash Detail for the board P A Surgeon J N Oakley, chairman, P A Surgeon M H Foster, recorder

Board to meet at Washington, D C, on the call of the chairman for the physical examination of officers for promotion and applicants for admission into the Revenue Cutter Service Detail for the board · Asst Surgeon General L L Williams, chairman, Asst-Surgeon General W J Pettus, recorder

---

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended March 18, 1904:

SMALLPOX—UNITED STATES

California San Francisco, Feb 21 28, 5 cases

District of Columbia Washington March 5 12, 2 cases

Florida Jacksonville, March 5 12, 2 cases

Illinois Belleville, Feb 26 March 12, 2 cases, March 5 12, Chicago, 1 case, Danville, 1 case, Galesburg, 1 case

Maine: Madawaska region, Feb 27 March 5, 11 cases

Maryland Baltimore, March 5 12, 2 cases

Michigan Detroit, March 5 12, 1 case

Missouri St Louis, March 5 12, 11 cases

New Hampshire Manchester, March 5 12, 5 cases

New Jersey Camden, March 5 12, 2 cases, 1 death

New York · March 5 12, Buffalo, 4 cases; New York, 5 cases.

Ohio · Cincinnati, Feb 26 March 11, 7 cases, 1 death; March 5 12, Dayton, 2 cases, 4 deaths, Toledo, 1 case

Pennsylvania March 5 12, Johnstown 1 case, McKeesport, 1 case; Philadelphia 48 cases, 6 deaths; Pittsburg, 2 cases, 1 case imported

South Carolina March 5 12, Charleston, 1 case, Greenville, 9 cases

Tennessee Nashville, March 5 12 12 cases

Wisconsin: Milwaukee, March 5 12, 3 cases

SMALLPOX—FOREIGN.

Austria · Prague Feb 20 27, 9 cases

Belgium · Antwerp, Feb 14 21, 7 cases, 4 deaths

Canada Ontario, 24 localities, Jan 1-31, 103 cases; Quebec, March 5 12, 3 cases

France Marseilles, Feb 1 20, 25 deaths, Paris, Feb 20 27, 38 cases 1 death

Great Britain Feb 20 27, Edinburgh, 16 cases, 13 deaths, Hull, 6 cases, Leith, 3 cases, London, 5 cases; Newcastle on Tyne, 5 cases; Nottingham, 14 cases; Glasgow, Feb 26 March 4, 30 cases, 2 deaths

India: Bombay, Feb 9 16 5 deaths, Karachi, Feb 7-14, 5 cases, 1 death

Italy: Palermo Feb 20 27, 1 case

Malta, Feb 13 20, 1 case, 1 death

Mexico: March 9. La Cananea, present; Magdalena, 8 cases, Torrsen, Feb 21, epidemic.

Netherlands: Amsterdam, Feb 20 March 5, 2 cases

Russia: Feb 13 20, Moscow, 8 cases, 1 death, Odessa, 2 cases; St Petersburg, Feb 13 27, 17 cases, 5 deaths.

Spain: Barcelona, Feb 1-29, 7 deaths; Santander, Feb 22 29, 4 cases, 1 death

Turkey: Constantinople, Feb 21-28, 5 deaths

YELLOW FEVER—UNITED STATES

Texas: Laredo, March 14, 1 case It is not yet determined whether this case was imported or not All precautions taken

YELLOW FEVER—FOREIGN.

Mexico: Merida, Feb 28 March 5, 1 case, 2 deaths

CHOLERA

India: Feb 6 13, Calcutta, 19 deaths; Madras, 1 death

PLAGUE—UNITED STATES

California: Concord, Feb 29, 1 death Bacteriologically confirmed March 12

PLAGUE—FOREIGN.

Egypt: Alexandria, Jan 30 Feb 13, 1 case

India: Bombay, Feb 8 16, 550 deaths; Calcutta, Feb 6 13, 45 deaths; Karachi, Feb 7-14, 69 cases, 34 deaths

---

Medical Organization.

Missouri.

Jasper County Association of Physicians and Surgeons.—Physicians of the county met at Joplin, February 25, and organized a medical society on the standard plan, with the following officers: President, Dr. John S. Long, Joplin; vice-president, Dr. William Lothian, Joplin; secretary, Dr. Joel E. Johnson, Joplin; treasurer, Dr. William H. Woodson, Webb City, and censors, Drs. James T. Stamey, Chitwood, Colby C. Gentry, Webb City, and Martin T. Balsley, Joplin.

Rhode Island.

Rhode Island Medical Society.—At the regular quarterly meeting of this society in Providence, March 3, the constitution and by-laws recommended by the American Medical Association was adopted. Dr. John Champlin, Westerly, was appointed delegate to the national association, and Dr. Frederick T. Rogers, Providence, alternate.

Tennessee.

Jackson County Medical Society.—This society was organized at Gainesboro March 14 Dr. S. Benjamin Fowler was elected president; Dr. Henry P. Loftis, vice-president, and Dr. Charles E. Reeves, secretary and treasurer, all of Gainesboro.

Texas.

Colorado County Medical Association.—Dr. Walter Shropshire, Yoakum, councilor for the Eighth District, organized a county association at Columbus, March 10, with an initial membership of 15.

Fort Bend County Medical Association.—This association was organized at Richmond, March 9, and the following officers were elected: President, Dr. J. Clyde Johnson, Richmond; vice-president, Dr. J. Mark O'Farrell, Richmond; secretary, Dr. Sidney M. Lister, Richmond, and treasurer, Dr. H. C. Boone, Fulshear.

Hays County Medical Association.—This society was organized at San Marcos with fourteen members and the following officers: Dr. Adam J. Beall, San Marcos, president; Dr. John C. Carpenter, Kyle, vice-president; Dr. Terry Kinney, San Marcos, secretary and treasurer; Drs. James H. White, Kyle, John C. Carpenter, Kyle, and Edgar P. Shelton, Dripping Springs, censors, and Dr. Robert C. Atkinson, San Marcos, delegate to the state association.

Navarro County Medical Association.—Dr. James J. Roberts, Hillsboro, met the physicians of the county at Corsicana, and assisted in the organization of a medical society on the standard plan, with the following officers: Dr. B. W. D. Hill, Dawson, president; Dr. John M V. Wills, Corsicana, vice-president; Dr. William T. Shell, Corsicana, secretary-treasurer; Dr. Clay Johnson, Corsicana, delegate to state association; Dr. Thomas V. Fryar, Corsicana, alternate, and Drs. Leslie E. Kelton, Corsicana, Wade D Fountain, Corsicana, and David B. Currie Kerens, censors

Society Proceedings.

COMING MEETINGS.

American Association of Pathologists and Bacteriologists, New York City, April 1-2.
Medical Association of the District of Columbia, Washington, April 5.
Tennessee State Medical Association, Chattanooga, April 12.
South Carolina Medical Association, Darlington, April 13.
Medical Association of the State of Alabama, Mobile, April 19.
Medical Society of the State of California, Paso Robles, April 19-21.
Florida Medical Association, Live Oak, April 20.
Medical Association of Georgia, Macon, April 20.
Mississippi State Medical Association, Jackson, April 20.
Texas State Medical Association, Austin, April 26.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 26-28.
Arizona Medical Association, Tucson, April 27-28.

NEW YORK STATE MEDICAL ASSOCIATION.

Special Meeting, held in New York, March 21, 1904.

The President, Dr. William H. Thornton, in the Chair.

[By telegraph from our Special Correspondent.]

The Consolidation Ratified.

A special meeting of the New York State Medical Association was held Monday, March 21, to hear and act on the report of the Committee on Conference with the Medical Society of the State of New York, concerning the proposed union of the two bodies. Dr. E. Eliot Harris, chairman of the committee, read the report and Dr. J. D. Bryant offered the following resolutions:

Resolved, That the report of the joint committee of conference be accepted, and that the proposed agreement for the consolidation of the Medical Society of the State of New York and the New York State Medical Association be and the same is hereby approved and the president of the association is hereby authorized and directed to execute the same in the name and behalf of the association, and the secretary is hereby authorized and directed to affix the corporate seal thereto, and be it further

Resolved, That the committee of the association heretofore appointed for the purpose of bringing about the consolidation, namely, Dr. E. Eliot Harris, Dr. Julius C. Bierwirth, Dr. Alexander Lambert, Dr. Parker Syms and Dr. Wisner R. Townsend, be and they are hereby continued as such committee, with full power and authority to do whatever may be necessary to carry the agreement into effect.

On motion these were unanimously adopted.

Action was also taken requesting the county associations in affiliation with the state association to ratify this action.

Thus the two state bodies have each unanimously voted in favor of amalgamation on the plans recommended by the joint committee.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Special Meeting, held March 21, 1904.

[By telegraph from our Special Correspondent.]

State Association's Action Endorsed.

Following the session of the New York State Medical Association reported above, the New York County Medical Association met and unanimously voted to ratify the action taken by the state association in approving the joint committee's plans for union. The resolutions passed were as follows:

Resolved, That the New York County Medical Association hereby ratifies, approves and adopts the agreement for the consolidation of the Medical Society of the State of New York and the New York State Medical Association, which was unanimously approved and adopted at the annual meeting of the Medical Society of the State of New York, held at Albany, Jan. 26, 1904, and by the New York State Medical Association at a special meeting held in New York City, March 21, 1904; and the New York County Medical Association hereby waives notice of an application to court for an order consolidating said corporation pursuant to the terms of said agreement, and hereby consents to the entry of such an order without notice; and be it further

Resolved, That the secretary of this meeting be and he is hereby authorized and directed to send a copy of these resolutions, duly certified by the president and secretary of the meeting, to the secretary of the New York State Medical Association, and to execute and deliver any and all waivers of notice of an application for such order as the court may require.

KANSAS CITY ACADEMY OF MEDICINE.

Regular Meeting, held March 5, 1904.

The President, Dr. C. A. Ritter, in the Chair.

Bronchial Sapremia.

Dr. Robert Sloan read a paper on this subject with a minute clinical report of a case. The features of the case were as follows: Cause, neglected influenza; patient an adult, male, persisted at his work for one week when a severe exacerbation confined him to his bed. The temperature was erratic for four weeks, ranging from normal to 104 F. There were frequent and irregular sweats and chills. There was severe pain in the left side of the chest with much coughing, foul tongue and fetid breath. The perspiration was very offensive and there was great muscular weakness. There were no physical signs of pneumonia. At first the sputum was scanty, but later a very offensive reddish-colored sputum was raised by paroxysms of coughing at intervals varying from one-half to five hours. This sputum had the appearance of being pneumonic, but was not glutinous and did not possess any cellular elements nor fibrin. It was rich in saprophytes and very acrid so that spasm of the glottis occurred with each expulsion. Acute laryngitis and tracheitis ensued. The salmon-colored sputum was small in quantity and perfectly distinct from the ordinary grip sputum, which was coughed up continuously. It was apparently due to putrefaction of bronchial mucus. The violent spasm of the glottis was controlled by spraying the larynx with adrenalin chlorid solution. Within a few minutes after the first putrid sputum appeared the voice, which had previously been normal, became hoarse and sank to a stage whisper. This condition remained for three weeks and then gradually improved for three weeks more, when it had returned to normal.

The diagnosis was grip complicated, not by pneumonia, putrid bronchitis, nor bronchiectasis, but by bronchial sapremia. The cause was probably the inhalation of a small particle of decomposing food or of inspissated mucus from the nasopharynx during an effort to clear that passage by quick, forcible inspiration through the nasal passages. The inspired particle probably entered a small bronchial tube and set up a localized putrefactive process instead of producing an aspiration pneumonia such as would ordinarily be expected.

DISCUSSION.

Dr. Frank J. Hall, who did the microscopic work on this case, said that he found a leucocytosis of 18,000 just before the first putrid sputum was expelled. In the sputum there was an abundance of Pfeiffer's bacillus and a great number of saprophytic germs, some motile and others non-motile. Some were a chromogenic and the color was due to chromogens which they generated.

The paper was also discussed by Drs. *Hal Foster, J. W.* Kyger and C. Lester Hall.

MANILA MEDICAL SOCIETY.

Annual Meeting, held at the Government Biological Laboratory, Jan. 4, 1904.

Officers.

The following officers were elected for 1904: Dr. R. P. Strong, president; Dr. W. E. Musgrave, secretary-treasurer; and the council as follows: Drs. Paul C. Freer, John Maye, John R. McDill, Paul G. Woolley and E. C. Carter.

Papers.

The papers were read by Drs. J. R. McDill and W. B. Wherry on an infection of the hand, by Dr. R. P. Strong demonstrating certain human parasites, and by Dr. F. W. Dudley. The latter is president of the board of health for Pampanga Province, and gave a very interesting statistical study of the prevalent diseases, their modes of transmission and the practices of the native physicians and the customs of the people in regard to medical matters.

Annual Report of the Secretary.

The report of the secretary for the year ending Dec. 31, 1903, showed that on Jan. 1, 1903, the society consisted of 14 active members. During the year 18 active and 3 associate members were admitted; 1 was dropped, 1 resigned and 1 died. This left 29 active and associate members.

By requirement of the constitution and by-laws, and acting under the direction of the society and its council, the secretary commenced early in the year to secure the names, addresses and other data of importance regarding every legalized practitioner of medicine in the Philippine Islands. This has been found to be a very difficult task and has only been completed within the past month. The large amount of necessary printing, paper, postage and typewriting necessitated the expenditure of considerable money. This desired data had all been secured, had been catalogued by the card index system, and was on file with the records and papers of the society.

Some very interesting information had been secured by these inquiries, which, it was announced, would be made the subject of a special report to the society.

Monthly Meeting, held Feb. 1, 1904.

This meeting was a very enthusiastic and interesting one. **Dr. Paul C. Freer** discussed the history of "Stereochemistry" from its discovery by Pasteur in the study of tartaric acid to the present time and applied its teachings to a theoretical explanation of immunity.

Surgery in the Philippines.

Dr. J. M. Banister, after giving a most interesting statistical report of more than four hundred surgical operations performed by himself and assistants at the First Reserve Hospital during the past year, refuted the statements sometimes made in the medical press of the United States that bad results often follow operations performed in the Philippine Islands and that convalescence was unsatisfactory. He showed that clean technic gave as satisfactory results in Manila as in any other country.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Feb. 10, 1904.

Dr. Samuel Wolfe in the Chair.

Mercury in Therapeutics.

Dr. I. Newton Snively read a paper on "The Unique Position and Value of Mercury in Therapeutics," in which he stated that in the frequency of its employment, it compared favorably with iron, but that here the similarity ended, the one being a builder up of tissue, while the other is a breaker down of tissue. He called attention to the fact that mercury had through all the ages occupied a prominent position in the materia medica, and reviewed the history of its use and the improvements in its administration in recent years. Without deciding on the relative cholagogic values of blue mass, calomel and corrosive sublimate, or their means of action, he stated that there was agreement among the profession on the main indications for the administration of calomel, when such symptoms are present as dull headache, yellow conjunctiva, constipation, sense of weight over the liver, no appetite and general lassitude, and whether the process takes place in one part or the other of the intestinal tract it is agreed that it acts on the small intestines and the upper part of the colon, hastening the contents downward, relieving hepatic engorgement, stimulating intestinal secretions and bile and producing large, watery stools. It is also of value in fractional doses in the early stages of typhoid fever and the diarrheal maladies of childhood. It passes through the stomach unchanged and thus does not interfere with the functions of this organ. Thorough trituration is of value and the joint administration of an alkali, preferably sodium bicarbonate, increases its effectiveness.

Therapeutics of Arsenic.

Dr. Howard S. Anders read this paper and stated that the drug was an alterative, and while referring to the fact that the exact conditions produced by it were not known he called attention to the necessity of carefully watching for symptoms of arsenical poisoning when the treatment is long continued. The drug is an improver of nutrition and it would seem to be a direct stimulant to nutrition, by diminishing or checking the tissue change and indirectly it improves the nutrition by increasing the recuperative powers, and it would seem that some individuals need arsenic to create a normal neuromuscular vigor, just as the syphilitic needs the iodids and the chlorotic, iron. He referred to the fact that Gautier of Paris had discovered arsenic in the human body and also that M. Berhand of Paris had discovered it in hens' eggs, which would indicate the necessity for supplying it when absent. In regard to its employment in tuberculosis, he acknowledged a hesitancy in its use on account of the likelihood of deranging the mucosa. The natural arsenical waters of Levico are valuable in some cases of this disease.

He stated that his experience with the drug in the treatment of chorea extended to about twenty cases, in all but two of which the administration in the form of Fowler's solution in gradually ascending doses, in conjunction with dietetic, hygienic and psychic measures, was satisfactory. He remarked that in St. Vitus' dance, the drug seemed to be almost a specific, and believed it was best administered by beginning with about three drops and increasing about two or three drops each successive day. He referred to the work of Rope, Waxham and others, the latter of whom recommends the hypodermic use of the arsenite of soda, beginning with 1/10 grain doses and rapidly increasing to 1/2 or 2/3 grain doses. He considered the drug of great importance in the treatment of chronic malaria, anemias, cachexias, in the recurrent malarial fevers, and in intermittent malarial neuralgias. He had suffered from tertian malarial fever each spring and autumn until he took the drug, off and on for three months, continuing until the first symptoms of gastrointestinal irritability manifested themselves, since which time (fourteen years ago) he has not had any symptoms of the disease In certain cases of pernicious anemia and arthritis deformans, he believed that it had a beneficial effect. In scrofulous conditions, glandular enlargement and bronchial catarrhs, it is also of value.

Digitalis.

Dr. William Egbert Robertson reviewed the various pharmaceutic preparations and their actions and believed the preparation made from Allen's leaves to be the most valuable. In regard to digitoxin the chemistry is very incomplete; it seems to have some effect in relieving the blood pressure, but during its administration the volume of urine and pulse rate should be noted from time to time in order to avoid the possibility of cumulative action. He preferred the infusion, and stated that he had not secured nearly so good results by using the digitalin as by using the digitalis in two-dram doses every three hours. The drug is employed chiefly for its effect on the circulation and especially after loss of cardiac power; in cases of weakness without valvular disease, in simple dilatation, and in all forms of valvular heart disease, especially mitral disease, it is of value. In simple hypertrophy, aneurism and a high degree of arterial sclerosis, it is contraindicated.

DISCUSSION.

Dr. Hobart A. Hare referred to the value of 1/200 grain doses of biniodid of mercury, in a watery solution every six to eight hours, for the purpose of aborting acute tonsillitis. He believed that all preparations of mercury were contraindicated in cases of tuberculosis, and believed that one of the chief reasons for the value of calomel in cases of intestinal disturbance was on account of its power of eliminating intestinal impurities. He believed arsenic to be of value in tuberculosis and anemia, as are also small doses of arsenate of copper in some cases of the latter disease, when iron does not seem to do so well. In regard to digitalis, he believed chemically and physiologically tested and carefully prepared fluid extract was the best, and recommended that the physician have it put up regularly in a known strength by certain reliable pharmacists. He felt that many cases of untoward results in the administration of digitalis were due to the fact that the physician was not thoroughly familiar with the strength. He also referred to the danger of the cumulative effect of digitalis, caused by the non-absorption of the drug at the time of its administration, believing that when the required dose is ascertained the patient should be kept there, instead of increasing it. Absorption is also aided by the conjoint administration of mild doses of Hoffman's anodyne.

Dr. Ludwig Loeb referred to the value of calomel in conjunction with some active diuretic in the treatment of dropsical conditions. In the administration of mercury in tertiary syphilis and other diseases, it is very apt to produce mercurialism, which should be carefully watched for and the drug discontinued so soon as these symptoms appear. Arsenic, he remarked, was particularly effective in diseases of the glandular structures. It is also of value in skin diseases, such as psoriasis and lupus, and in anemia. Digitalis he did not view as a true dieuretic, but rather as a heart tonic, acting by stimulation and thus increasing the circulation and secretion of urine.

Dr. Walter I. Pennock referred to the difference in strength of the various drugs put up by the different houses and urged the necessity for uniformity in this direction. He believed as good results were secured by fractional doses of calomel as by a single large dose. He stated that he had never seen a case of the cumulative action of digitalis, and believed the best results would be produced by use of the fluid extract, and after getting up to a sufficient dose by dropping back again to about half that amount, and again gradually increasing.

Dr. William L. Pepper stated that he had treated thirteen cases of diphtheria in one house with biniodid of mercury and that all recovered.

Dr. I. Newton Snively stated that he believed the value of any drug depended on the amount which was absorbed. In the administration of calomel, he recommended 1/10 of a grain every hour, combined with bicarbonate of soda and thoroughly triturated, and believed that the best results were secured with fractional doses.

Dr. Howard S. Anders believed arsenic to be of value in cases of tuberculosis when fever was absent, and urged the necessity of carefully prepared preparation of digitalis of uniform strength.

Dr. William Egbert Robertson stated that the effect of the fluid extract of digitalis on the stomach is less retained than is that of the ordinary preparations employed. He thought the infusion less reliable. He had previously stated that mercury may produce a nephritis. Now Kauffman and other German pathologists have called attention to the nephritic condition following the drug.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Urotropin in Scarlatina.

According to J. Widowitz, in *Interstate Med. Jour.*, the administration of urotropin prevents the occurrence of nephritis after scarlet fever. Proceeding on the hypothesis that scarlatinæ nephritis is due to a bacterial lesion of the kidney, the author prescribes urotropin at the beginning of the attack for a few days, and then again during the third week, in doses varying from grain 1 (.06) to grains 7½ (.50) three times a day, according to the age of the child. This treatment was carried out in 102 cases, and nephritis did not occur in any of them.

Cystitis.

The following combinations are recommended by *Merck's Archives* in the treatment of cystitis:

℞.	Potassii citratis	ʒv	20
	Potass. bicarb.	ʒv	20
	Ext. hyoscyami flu.		
	Spts. menth. pip., āā	ʒiss	6
	Syr. limonis	℥ii	60
	Infusi lini (5 per cent.)	Oi	500

M. Sig.: One tablespoonful in a glass of water every hour until improvement is shown, then every two or three hours, according to the symptoms; or:

℞.	Olei santali	gtt. v	30
	Olei terebinthinæ	gtt. ii	12
	Olei cinnamomi	gtt. ss	03
	Formini	gr. iiss	15

M. Ft. cap. No. i. Sig.: One such capsule every three to six hours; or:

℞.	Formini	ʒiiss	10
	Potass. citratis	ʒv	20
	Potass. bromidi	ʒiiss	10
	Tinct. hyoscyami	℥i	30
	Ext. tritici flu.	℥iss	45
	Glycerini	℥ss	15
	Syr. rubi idali q. s. ad.	℥viii	240

M. Sig.: A dessertspoonful in a glassful of water three times a day.

[Formin is hexamethylene-tetramine, and is identical with urotropin.]

Sea Voyages.

The advantages of the ocean climate, according to S. Solis-Cohen, in *Amer. Med.*, are its equability of temperature depending on the radiation and absorption of heat by the mass of water, the abundance of light, the freedom from dust and microbes and other impurities of the air, and the favorable atmospheric humidity. The prolonged rest and complete change of surroundings are important features in the curative effect of sea voyages.

The disadvantages are the monotony, the cost, the poor ventilation of the cabins, the danger of poor food and the possibility of seasickness. A sailing vessel, according to the author, is preferable to a steamship. After such depressing affections as influenza, short sea voyages are of value in giving mental and physical rest. In cases of neurasthenia longer voyages of one or two months are useful, also sometimes in asthma, in scrofulous conditions and frequently in incipient tuberculosis, prolonged voyages, in which port is not touched, are recommended only where there is high resistive power or in cases of drug habitués. Patients with severe cardiac disease should not take ocean trips at all. In cases of advanced tuberculosis, chronic gastro-intestinal disorders, cholelithiasis, ocean trips of more than one week's duration should not be taken. Neuralgic and gouty patients are frequently worse on the ocean than at home.

SEASICKNESS.

In the treatment of seasickness the author recommends as a preventive that all work be abolished for twenty-four hours before embarking, so that the system may not be exhausted, and as hearty a meal as possible be eaten before going on board. A calomel purge followed by a saline should be taken one week before sailing, and repeated two days before sailing. Saline laxatives or enemas should be used daily for the first few days on board ship. Light, easily digested food should be taken at frequent intervals. Strychnin, atropin or preferably picrotoxin should be given in small and frequent doses for a few days before sailing, and continued until the "sea legs" are gained.

In his opinion suprarenalin in doses of grain 1/24 (.0025) to grain 1/12 (.005) dropped on the tongue, is of value in some cases. After seasickness has set in, small amounts of light foods, such as soups, junket, beef juice and peptone should be taken at short intervals. Effervescent drinks, such as champagne and seltzer, are frequently of service, as well as counterirritation over the epigastrium. He recommends, in some cases, the Winternitz combination compress, which consists of a cool compress enclosing a warm epigastric coil as of value in this form of vomiting. In addition to the laxative treatment, the bromids, chloral and other hypnotics are valuable. The author prefers the bromids and occasionally morphin. The vasomotor stimulants, such as cocain, strychnin and atropin, may also be of service.

Agalactia.

The following combination in *Med. Record*, is recommended in the treatment of agalactia:

R.	Strych. sulph.			
	Pilocarpinæ hydrochlor., āā	gr. i		06
	Sacch. lactis	ʒiiss	10	

M. Ft. cap. No. 60. Sig.: One every four hours.

Epilepsy.

The following combination is recommended by W. Alessi in the treatment of epilepsy:

R.	Sodii arsenatis	gr. 1/60		001
	Zinci phosphidi	gr. 1/12		005
	Calcii phosphatis	gr. iss		09
	Sodii benzoatis			
	Pancreatin, āā	gr. iii		20

M. Ft. cap. No. i. Sig.: One such capsule after each meal.

The arsenic and zinc are nerve tonics. The calcium phosphate reduces cerebral excitability. The pancreatin and sodium benzoate aid digestion and overcome intestinal fermentation.

Chronic Bronchitis.

In the treatment of the dry catarrhal form of chronic bronchitis, T. A. Claytor, in *Wash. Med. Annals*, recommends the following combination to control the cough:

R.	Pulv. ipecac. et opii	gr. iii	20	
	Pulv. capsici	gr. ss		03

M. Ft. cap. No. i. Sig.: One capsule every three hours.

For the relief of dyspnea, difficult cough and tenacious expectoration a combination similar to the following is recommended:

R.	Potass. iodidi			
	Potass. bicarb., āā	ʒiss	6	
	Ammon. chloridi	gr. xlv	3	
	Ext. glycyrrhizæ flu. q. s. ad	℥ii	60	

M. Sig.: One teaspoonful four times a day in water.

For the morning cough, when the patient complains of much difficulty in raising the phlegm which has accumulated, the following is recommended by the author:

R.	Sodii bicarb.	gr. xv	1	
	Sodii chloridi	gr. v		30
	Spts. chloroformi	gtt. x		65
	Aquæ anisati q. s. ad	℥ss	15	

M. Sig.: To be taken at one dose in warm water, on waking.

Tar is also recommended as a very efficient remedy, taken in the form of a pill, each grains two (.12), every two or three hours, or as the syrupus picis liq., two teaspoonfuls in water every three or four hours, or combined as follows:

R.	Syr. picis liq.	℥ii	60	
	Syr. pruni virg.	℥i	30	

M. Sig.: A dessertspoonful to a tablespoonful every three or four hours.

The foregoing, in the opinion of the author, is the ideal combination as a cough mixture in chronic bronchitis.

In the treatment of bronchorrhea creosote, oil of eucalyptus and terebene are the best preparations. The author prefers eucalyptus given as follows:

R.	Olei eucalyptus			
	Olei amygdalæ dulcis, āā	gtt. v		30

M. Sig.: Drop the entire amount into a capsule and take one such capsule every three hours, followed by a full glass of water.

Terebene may be taken in doses of ten minims each (.65) dropped on a lump of sugar or placed in a capsule.

In the dry catarrh Yeo recommends the following:

R.	Sodii bicarb.	ʒi	4	
	Sodii chloridi			
	Ammon. carb., āā	ʒss	2	
	Spts. chloroformi	ʒii	8	
	Aquæ q. s. ad	℥vi	180	

M. Ft. mistura. Sig.: Two tablespoonfuls with the same amount of hot water every four to six hours.

Along with this combination the author recommends the following:

R.	Antimonii tartarati	gr. 1/6		01
	Morph. acetatis	gr. 1/8		008
	Ext. hyoscyami	gr. ii		12

M. Ft. pil. No. i. Sig.: One such pill at bedtime; or:

R.	Pulv. ipecac.	gr. 1/8		008
	Codeinæ	gr. ss		03
	Ext. hyoscyami	gr. ii		12

M. Ft. pil. No. i. Sig.: To be taken at bedtime to allay the irritative, hyperesthetic condition of the bronchial surface.

In cases of bronchorrhea copaiba is recommended, combined with tar, in capsule form or according to the following formula:

R.	Copaibæ	ʒii	8	
	Mucil. acaciæ	ʒvi	24	
	Spts. chloroformi	ʒss	2	
	Aq. camphoræ q. s. ad	℥vi	180	

M. Ft. mistura. Sig.: Two tablespoonfuls three times a day.

Turpentine is a more agreeable preparation, and is very efficacious prescribed in capsules or given in the form of an emulsion as follows:

R.	Olei terebinthinæ	ʒi	4	
	Mucil. acaciæ	℥ii	60	
	Misturæ amygdalæ q. s. ad	℥vi	180	

M. Ft. emulsio. Sig.: One or two tablespoonfuls three or four times a day; or it may be given in the form of an inhalation, placing a teaspoonful of turpentine in a pint of hot water, and directing the patient to inhale the vapor.

Analgesic for Rheumatism.

The following combination is recommended as a local analgesic in the treatment of rheumatism:

R.	Menthol	ʒi	4	
	Betulol			
	Ceræ albæ			
	Lanolini, āā	℥i	30	

M. Ft. unguentum. Sig.: Apply with friction if possible. If the joint is too tender apply on lint.

[Betulol is methyl-oleo-salicylate compound.]

Medicolegal.

Confining Smallpox Patient in Unsanitary Pest-House.—The Court of Appeals of Kentucky says that it was alleged in the case of Having vs. the City of Covington by the party suing for damages that he was taken against his will when sick with smallpox and confined in a pest-house, which was unfit for any one, well or sick, to remain in; that the roof was broken, and the sides of the house open, so that the rain, snow, and ice could come in and on him; that he was placed in a filthy, unhealthy, and damp room, and compelled to remain there; that the bed, bedding, and covering and place where he was kept were unfit for any one to occupy; that, because of the cold, sleet and snow, and other elements, and the filthy condition of the rooms and bedclothing, he suffered both mental and physical pain and anguish, and that the ravages of the disease with which he was afflicted were increased by reason thereof. The court says that it was agreed that the officials who committed the wrongs complained of were personally liable for the injuries received, and the only question to be determined was, could the city be made liable therefor? One of the general principles underlying the administration of government of municipal corporations is that, in the preservation of the peace, public health, maintenance of good order, and the enforcement of the laws for the safety of the public, they possess governmental functions, and represent the state, and under that principle a city is not liable for the malfeasance, misfeasance, or nonfeasance of its officers. With reference to the matters alleged, the city, by its officials, was acting for the preservation of the public health, and in a governmental capacity, and as an arm of the state government. All the authorities support this conclusion, and there is no deviation from these principles, except where the city is made liable by an express statute. There being no statute making the city liable in this case, a judgment, on demurrer, in its favor is affirmed.

Question of Skill for the Jury—Quoting from Books.—The Supreme Court of California says that, in the malpractice case of Bailey vs. Kreutzmann, the physician sued examined Mrs. Bailey and pronounced her ailment to be a cystic tumor of the ovary, and ordered her to a hospital, where he proceeded to operate on her for the said ailment. After an abdominal incision and careful inspection of the parts, he discovered that the ovaries were in reasonably good condition, and, finding the uterus enlarged, concluded that the patient was probably pregnant, and sewed up the incision. The wound healed, and subsequent events proved that she was not pregnant at the time of the attempted operation. Thereafter the physicians and surgeons called as witnesses reached the conclusion, from the history of the case and all the circumstances surrounding it, that the patient's trouble was neither pregnancy nor an ovarian tumor, but was in fact a fibroid tumor of the uterus, or something else nearly allied thereto. The patient and her husband brought this suit to recover $40,000 for the alleged unskillful and negligent acts of the physician. The verdict and judgment were in the physican's favor; but the Supreme Court has reversed an order denying a motion for a new trial on account of certain errors. At the request of the physician, the jury was instructed: "The defendant in this action is not charged by the plaintiffs with any lack of general skill or competency as a physician and surgeon. This amounts to an admission, and you are bound to hold, accordingly, that the defendant was possessed of that ordinary medical and surgical knowledge and skill which the law requires him to possess; there being no degree other than that of ordinary knowledge and skill recognized by law as a standard or applicable as a measure of knowledge and skill in such cases." The Supreme Court holds that this instruction was erroneous, and should not have been given. The plaintiff charged the defendant with negligence and want of skill in treating her, and should have been left to argue to the jury that the facts presented showed that the defendant was lacking in the skill usually possessed by a physician and surgeon. Again, the court says that it has been held, without conflict and in an extended line of cases in California, that medical works are hearsay and inadmissible in evidence, except, perhaps, on cross-examination, when a specific work may be referred to, it seems, to discredit a witness who has based his testimony on it; and it must be taken as the settled rule in the state that medical books are not admissible as evidence, except in the instance specified. If the books themselves are hearsay and inadmissible, certainly any recital of their contents or the substance thereof is none the less hearsay, and should be excluded for that reason.

Physical Examination of Eyes Requiring Use of Drugs.—The case of A., T. and S. F. Ry. Co. vs. Palmore, as it is entitled in the Supreme Court of Kansas, was brought by the latter party to recover damages for injuries to his eyes alleged to have been sustained while in the company's employ handling creosote treated ties. Before the trial began the company made a request for an expert physical examination of his eyes in the usual and ordinary manner. No objection was made to the time or form or propriety of the request. On behalf of the party it was stated that he consented that the experts might examine his eyes by inspecting them, but that he protested against the court permitting experts or anybody else to put drugs into his eyes for the purpose of dilating them. No reason whatever for this protest was vouchsafed. On the part of the company it was suggested that in no instance could a proper examination of the eye be made without dilating certain of its parts, and the request was made that this feature of the examination be left to the experts themselves. Thereupon, the trial court made the following order: "The plaintiff, by his consent, may subject himself to have his eyes examined, but the court will not permit any drugs to be used in the examination without the consent of the plaintiff." The Supreme Court holds that this was error. It says that it is a matter of common knowledge that, through the restriction of the energies of trained students and investigators to that single field, ophthalmology has been brought to a state of comparative perfection. Here, as in all other quests for truth conducted under the guidance of the scientific method, the first requirement is a full and accurate observation of the facts. The modern scientific expert will be content with nothing short of a view of the facts where they can be seen. Therefore he has invented the ophthalmoscope for the exploration of the interior of the eye, the rhinoscope for the exploration of the nasal cavities, and other appropriate instruments for the exploration of other hollow organs of the body, and he will not attempt to bridge the chasm between ignorance and knowledge in any case where they may be of assistance until he has availed himself of their use. The question, therefore, arises whether or not the law, as a means of justice, will tolerate any other than the surest method of ascertaining truth; whether or not, with all the marvels of scientific achievement placed at its command, the rule of thumb shall be sufficient for its purposes; and whether or not in this case the timely application of the company for the production of the best evidence should be granted before a transfer from its treasury to the party suing of $5,000 was ordered. Again, it says that drugs are of infinite shades of potency from the rankest poisonousness to absolute innocuousness. They may produce death, or an effect so fleeting and temporary that only the most skilled observer can be conscious of it; and reactions from them range from the utterly intolerable to the positively pleasurable. The question, therefore, was not if drugs should be used, but if an examination should be made without serious inconvenience and without deleterious effect. Any enforced examination is vexatious and embarrassing, and very frequently must involve some slight degree of that discomfort which is denominated pain; but an examination may nevertheless be made with due consideration of both the sensibilities of the party suing and the demands of justice. From all this, including an examination of a number of authorities more or less in point, the Supreme Court says that the conclusion must follow that the District Court should have required an expert examination of the plaintiff's eyes to be made, subject to the limitation that it should not produce serious discomfort or any deleterious consequence; and, in order to insure the execution of its order according to the strict letter of its terms, the court should have approved, if it did not actually select, the experts appointed to make the examination. Or, as it sums it up, in an action for damages for a negligent injury to the eyes, claimed to be permanent, a timely request for an expert physical examination of the injured organs in the usual and ordinary manner should be granted, although involving the use of drugs for dilating the pupils of the eyes, subject, however, to the limitation that the examination does not produce serious discomfort or any deleterious consequence.

1. **Iron in Therapeutics.**—Wilcox discusses the pharmacology of iron, and remarks that the term "organic" iron should be considered obsolete and the term "masked" substituted. The hemoglobin can not be taken into account as it is destroyed so soon as it enters the stomach, therefore blood products for administration are useless. Undoubtedly many so-called organic iron compounds are practically only combinations of iron salts with albuminoids. This is shown by the addition of a few drops of silver nitrate solution which causes albuminoid precipitation. In true masked iron the addition of hema-

toxylin solution causes no color reaction. In determining the *form of masked or organic* iron for oral administration he says that one should be selected which 1, should be of definite chemic composition; 2, does not precipitate with a silver nitrate solution; 3, does not give the blue-black color with MacCallum's test; 4, is not decomposed by the hydrochloric acid of the gastric juice; and 5, it must show definite results in an increase in the number of red blood-corpuscles and in the amount of contained hemoglobin. These requirements are evidently the most rigorous which can be devised, and in meeting them modern iron therapy will be placed on a secure foundation.

2. **Alopecia Areata.**—This disease is considered by Dillingham as parasitic in nearly all cases, and should be treated as such, as is the case in France. The best results can usually be obtained from chrysarobin which can be painted on after dissolving in liquid gutta-percha or used in vaselin, which latter plan gives the best results. The strength of the ointment varies from 20 gr. to 2 drams to the ounce, and depends on the age of the patient and the susceptibility of the skin. Care should be taken in keeping it out of the eyes and not using it on too large a surface at a time. He also advises the use of stimulating lotions to cause an increased blood supply to the part.

4. **Metapneumonic Empyema.**—Morse describes the onset and symptoms of empyema occurring after pneumonia, especially in early age, and gives his conclusions as follows:

> Metapneumonic empyema usually develops during the last days of the pneumonia or during the first days after the crisis, but in rare instances may develop in the early days of the pneumonia, or later during the convalescence. Persistence of the fever and other symptoms after the time of the expected crisis or their recurrence after the crisis should always suggest the possibility of an empyema. There is nothing characteristic about the symptoms of empyema, which are those common to all severe pulmonary affections. Rapid emaciation and progressive pallor are the most constant symptoms in neglected cases, while chills and sweating are unusual. Enlargement of the affected side as a whole is more common than flattening or bulging of the intercostal spaces. Flatness in Traube's space is less constant in left-sided effusions in infants and children than in adults. The most constant and characteristic sign of effusion is a marked sense of resistance on the affected side. Displacement of the heart almost always occurs, and next to the sense of resistance is the most important sign. These two signs justify the diagnosis of effusion even if all the *other physical signs are inconsistent.* Dullness or flatness is almost always present, but may be replaced by tympany. The respiratory sound is almost invariably bronchial or bronchovesicular in character, and, as a rule, diminished in intensity. Loud, bronchial respiration is, however, not uncommon, even with large effusions, and counts very little, if at all, against the presence of fluid. The vocal resonance is very variable, both in character and in intensity and is of little value in diagnosis. It is very difficult to determine the vocal fremitus satisfactorily. Its absence is, however, an important diagnostic sign. Râles may be transmitted through large amounts of fluid. Their presence does not rule out an effusion.

5. **Olive Oil in Dysentery.**—A special treatment is here proposed by Rutherford for cases of chronic dysentery, sprue, and chronic enterocolitis of tropical origin. A number of patients were selected for the treatment and the results were such that he considers the oil decidedly curative. It increases the flow of watery bile which favors the absorption of fats in the intestines and stimulates intestinal peristalsis, acts as an intestinal antiseptic and destroys certain pathogenic bacteria. The results of the administration are positive evidence of the increased quantity of bile; decrease in the number of daily bowel movements and improvement in their character; gradual cessation of signs of fermentation and putrefaction along the gastro-intestinal tract and resulting subsidence of pain and tenderness, with a general improvement, increase of appetite, improved digestion, improvement of the nervous system and rapid gain in weight and strength. There was an apparent positive cure in an average time of two months and upward with a few recurrences to date. The usual way of giving it was to begin in the first period of treatment, with 30 c.c. of the oil three times per day for the first three days, then increased to 60 c.c. three times daily, and on the sixth day, is again increased to this quantity four times in the twenty-four hours. During the first half of this period the patient is given only a milk diet; in the latter half there is added to it one to three ounces of scraped beef or its equivalent in egg albumin daily. By this time the patient becomes tolerant of the oil. He may lose in weight temporarily. In the second period of the treatment the oil may be given in greater quantity, not less than 90 c.c. three times daily, without discomfort, and kept up for perhaps two months or more in chronic cases until the patient's recovery has been fully established and the normal weight restored. In the third, or getting-up period, the patient is gradually restored to a full diet and the oil decreased. In most cases in the beginning it is necessary to give with it about equal quantities of hot milk until the patient gains a tolerance. Later on, a relish for the oil is obtained. It is given about an hour before meals, so as to get the maximum effect on the empty stomach and intestines. The oil must be the pure olive oil. In a special report to the commanding officer by Dr. G. Parker Dillon the results are given mainly as stated, but he does not feel sure that relapses will not occur, but the oil treatment is guardedly approved.

12 *The Prognosis of Idiopathic Pleurisy. George G. Sears.

9 and 10.—See abstract in The Journal of February 6, p. 391.

11. **X-Rays and Radium.**—Williams finds that the rays from radium salts, unlike the x-rays, are not useful in diagnosis either by radiographs or fluoroscopic examination. The beta rays from radium salts will heal some cases of new growth that are not cured by the x-rays, and act more promptly, though over a more limited surface than the x-rays. Radium salts at an activity of 8,000 or considerably more, are not strong enough to be efficient. Pure radium salts which have a radioactivity of about 1,500,000 are not too strong for the work to be done. Radium rays, unlike the x-rays, are uniform, and great care should be exercised to avoid burns.

12. **Idiopathic Pleurisy.**—Sears has investigated a number of cases of idiopathic pleurisy for the purpose of estimating their relation with tuberculosis. The tables show that a considerable proportion at least becomes tuberculous. He thinks that the results do not support Cabot's hopeful view, but rather raise the suspicion that an attack of pleurisy may be a manifestation of a suspected taint causing death at a later period. How great the damage is he does not say, but the conclusions which he considers justified are to the effect: 1. That about 10 per cent. of his 439 cases plus Cabot's 300 are known to have developed tuberculosis. 2. That over 55 per cent. of all cases which were followed to their death had died from some form of tuberculosis. 3. That tuberculosis, when it occurred, developed within five years in over 50 per cent. and within ten years in over 70 per cent. 4. That this danger is much increased by a tubercular family history or a personal history of some form of tuberculosis previous to the attack.

19 Remarks on the Preparation of Vaccine Virus. John F. Anderson.

13. **Secondary Laparotomy.**—By secondary laparotomy, of course, is understood an operation undertaken months or years after a previous section for the relief of the symptoms that were either not relieved or have developed subsequently. Among these symptoms are adhesions which are not always well accounted for, and it would be interesting to know how far gauze drainage is responsible. It is difficult to explain how in many cases where large raw surfaces are left and also infected stumps, adhesions either do not form or give rise to very little trouble. Fistulæ are annoying complications and

while they generally heal, now and then a secondary operation is required. Secondary pus foci may be evidences of imperfect work. Hernia, Coe does not here consider. The development of neoplasms of the uterine adnexa and the broad ligaments after previous operation are too common to require comment. His personal experience has led him to remove the opposite ovary, even though macroscopically healthy, when its fellow is the seat of papilloma, since he finds that the remaining organ is usually affected later. He generally tries to preserve the functions when he can, but finds that sometimes the most promising cases are the most disappointing in this respect. Conservative operations on the ovaries are often followed by troublesome complications. He asks whether in doubtful cases it would not be wiser to leave an ovary alone if we do not feel justified in removing it. His experience at Bellevue has made him dubious as to the complete elimination of fresh gonorrheal or septic infection by preliminary curettement, or catheterization and irrigation of infected tubes. The frequency with which a diseased appendix is found after laparotomy is a strong argument in favor of its general removal. The principal indication for secondary operation, however, is pain, and hemorrhage may often require it. He remarks in regard to the diagnosis, and says that the prognosis should be a guarded one as to complete relief, though in operating in certain obvious conditions—neoplasms, persistent hemorrhage, etc.—we may confidently expect positive results. When it comes to the question of separating dense adhesions or dissecting out exudates, we should not forget that they may recur in spite of everything. There is generally relief, however, and it is sometimes permanent. The cure of fistula is often difficult and prolonged, and even then recovery may be doubtful. While he has confined his remarks on secondary operations to abdominal section, he admits that for the simple removal of the uterus and the remains of the adnexa he would prefer the vaginal route, but he can not admit that adhesions above the pelvic brim can be thus treated. A surgeon can hardly be too radical at his second seance and he usually has the full cooperation of his patient on this occasion. The man who discovers a sure method of preventing the re-formation of adhesions will deserve the lasting gratitude of the world.

15. **Strangulated Hernia.**—Erdmann analyzes 58 cases occurring in a practice of about eight years: 31 being inguinal hernias, all males, of whom 26 recovered. The details of the five deaths are given. Strangulation in every one of these cases was at the external abdominal ring. There were 19 cases of femoral hernia; 4 in males and 15 in females. There were 3 cases of excision of the intestine, 2 recovering; 6 cases of umbilical hernia, all females, and 1 death. He would use general anesthesia in these cases if the patient has not been vomiting, but in case of vomiting, local or spinal anesthesia should be employed. He prefers, however, local anesthesia in all instances as being less likely to cause vomiting and inspiration pneumonia and lessening shock. There is no reason for not allowing the hernial gut to remain in the wound for a number of hours if there is a question as to its viability. If time shows that it is non-viable, a secondary operation with excision and radical cure can be proceeded with. He also returns the omentum when not gangrenous unless it is matted together by adhesions or hypertrophied. In excising the omentum he never uses the locked or chain ligature because it puckers up the mass. He prefers to take up small sections and make individual ligations, keeping the omentum in its spreading relationship to the intestine. The youngest case was a male thirteen days old; no anesthesia; recovery. The oldest was a female aged 86; femoral hernia; local anesthesia; recovery. The majority of the cases seem to occur during the warm weather when general relaxation is greatest. He does not believe in taxis. The after-treatment is simple. A little rise of temperature, ½ to 1½ degrees, is nothing to be feared, but the dressings should be taken down occasionally so that the wound can receive proper attention. A movement of the bowels is sought for in all non-excision cases the second day, and a light diet given until the temperature is normal. In excision cases enemas are used for the first week and rectal alimentation from four to six days; food by the mouth after the sixth, and a light diet after the tenth. The complications of inspiration pneumonias and solitary follicle ulceration are briefly mentioned. In uncomplicated cases he allows the patient the head and back rest after the fourth day and to be out of bed on the thirteenth or fourteenth in inguinal and femoral hernia. In abdominal hernia they are out of bed in three weeks with a snug binder.

16. **Tuberculosis.**—Freudenthal calls attention to laryngeal and pharyngeal disorders in the diagnosis of early tuberculosis, pointing out the characteristic appearances, anemia of the soft palate with a congestive condition of the uvula and fauces, which is an early symptom, and congestion of the larynx with pallor of the epiglottis. The use of the old Koch tuberculin is considered by him comparatively safe. He has had only a limited experience, however, in 31 cases, and can not record any unpleasant results. The individual dose ranges from .5 to 2 mg., increased if there is no reaction to 3 or 5 mg. and even more. He thinks it should be tried on a larger scale. He speaks well of electric light as a therapeutic agent in tuberculosis, and also of carbonic acid gas, though its use seems to have been forgotten. In summing up his experience, which will be published more fully later, he says that the addition of CO_2 to treatment with the so-called blue rays of light has given encouraging results and promises more for the future.

25 *The New Biologic Test for Human Blood, with a Report of Its Employment in a Recent Murder Case. (Concluded.) A. Robin.

20. **Intestinal Anastomosis.**—Hepperlen uses a gelatin capsule for the bobbin or cylinder over which to suture the intestine. It serves as a firm support and is readily absorbed after the operation. He has them made of various sizes, having them slightly formalinized so that they will retain their shape at least fifteen minutes anywhere within the alimentary canal, and then completely dissolve. He describes his technic as follows:

> When the capsule is placed in position I insert a few interrupted sutures through all the coats of the bowel to hold the parts in coaptation. I then complete the work by using a suture that I have never yet seen recommended. I use a fine intestinal silk, twenty-four inches long, doubled, with a needle on each end, having the knot where the ends of the silk are tied in the center. I start my first suture under the mesentery attachment, inserting a needle with each hand at the same time through the two outside coats of the bowel, an eighth of an inch from the cut margins; pick up a loop about one-twelfth of an inch in length, according to the method of Lambord, draw the parts together and tie them at each stitch. Continuing thus until I have completely encircled the bowel, I close the mesentery opening with the same suture, being careful to pass my needles under the small vessels in the peritoneal coat so as not to constrict the blood supply more than necessary.

The figures appended to the text illustrate the method. The advantages he claims are first, its simplicity; second, it can be introduced, practically without handling the parts, in about a quarter to an eighth of the time required for any other stitch, and third, when the bowels are sewed together by this method they are held more firmly than by any other stitch he knows of. In fact, in using experimentally much pressure where this method has been employed, he has had the intestine give way at other parts than at the point of suture. By the aid of the capsule and suture recommended, end-to-end anastomosis can be performed in five to ten minutes.

22. **Senile Pneumonia.**—In this clinical lecture Solis-Cohen calls attention to the treatment of pneumonia in elderly persons, and the various drugs to be used. Alcohol is given in the form of champagne, which he thinks is better as causing less stomach irritation, and it is more readily accepted when alcoholic stimulation is required. A saline infusion under the skin was given, which is a useful practice when the injection is done slowly and does not exceed eight to twelve ounces at a time. Hot flaxseed poultices were kept about the thorax

during the day and at night were replaced by a lamb's wool jacket for the better part of a week. In using poultices it is important that they should be well made and retain their heat for at least four hours so as not to disturb the patient too frequently. It is not wise to awake the patient either for food, medicine or any applications. At one time in the treatment oxygen was given by inhalation. It is a useful remedy but is usually put off too long. He describes his method of giving it, using the purified gas under compression in a cylinder to which a wash bottle and inhaling terminal are attached. He gives the oxygen very quietly for a considerable period of time; in severe cases from one hour to six or twelve, or even more, removing it only when needed to give the patient rest or sleep or food. After two or three hours of continuous administration of oxygen there will usually be sufficient improvement to warrant its intermittence for a couple of hours. Half an hour's use of oxygen in every two or three hours may suffice. The administration should be entrusted to skilled hands and the dosage regulated according to circumstances. He remarks as regards temperature that a high temperature is a favorable symptom; a low temperature, as a rule, is bad. Hence this indicates the danger of antipyrin medication. Many patients, he thinks, suffer from heart failure owing to the use of the coal-tar antipyretics either for the pneumonia or because previously employed.

23. **"Writer's Cramp."**—Norstrom describes "writer's cramp," holding that it is not necessarily a nervous affection, and pointing out that in many cases at least it is myositic and with a tendency to hardened nodules in the muscles, often multiple. The massage applications to be used are effleurage and proper friction. He thinks that in many cases in the future a careful examination will reveal the presence of peripheral changes of the type described. Not all the cases perhaps are due to chronic myositis or all curable by massage. There are some cases where no deposits are found, but these are exceptional. He mentions several of this type. Massage can not be effective when nothing tangible can be detected in the muscles, but in the majority, the condition, he holds, is due to myositis with localized lesions.

24. **Rectocolonic Lavage.**—Murray describes the rectal tubes which he has devised and which he thinks meet the indications better than any others. The tubes are solid and rounded at the head with a double perforation allowing inlet and outlet; are very soft and pliable; the distal outlet and inlet made on a curve. Being made of soft rubber they can not break and can be used with water of a higher temperature than can be done with metal or hard rubber. The paper is illustrated, which makes the descriptions very intelligible.

25. **Biologic Test for the Blood.**—In this continuation of his paper Robin describes the tests as made in a special medicolegal case, and also gives his conclusions as follows:

1. Human blood can be distinguished from that of other animals, except, perhaps, monkeys, by means of antiserum.
2. Antiserum may be obtained by immunizing rabbits against human blood.
3. For immunization, it is most convenient to employ the blood obtained from human placenta, which can be secured aseptically without much difficulty.
4. From six to eight injections, 8-10 c.c. each, should be made at intervals of three to five days, and the serum secured at least a week after the last injection.
5. At the end of the immunization period it is well to test the potency of the antiserum by securing a small quantity of blood from the ear vein or any of the deep-seated vessels.
6. To obtain the serum from rabbits for testing purposes, it is not necessary to sacrifice the animal as sufficient serum can be secured from any of the large veins or arteries, the femoral being the most accessible.
7. Care should be taken to have all solutions perfectly clear and the blood sufficiently dilute. The antiserum should be used pure.
8. Control tests on blood from different domestic animals should invariably be made.
9. With all the precautions observed, a distinct clouding within thirty minutes and a precipitate within two hours is certain evidence that the blood is human.
10. In medicolegal cases the tests should be repeated at least twice, so as to exclude any possible error.

26. **The Shiga Bacillus in Infants.**—The material used by La Fetra and Howland was obtained during the months of July, August and September. Sixty-four cases were examined consecutively and 62 gave a positive reaction. From an analysis of the cases they give the following facts as specially worthy of notice:

1. The unexpectedly great prevalence of the dysentery organism in cases of diarrhea in infants, at least during the summer months. Thus, out of 64 consecutive cases examined in the Vanderbilt clinic, 62 were positive. As has been mentioned before, this is the first large series of cases examined seriatim that has been made and the result is certainly striking. It is all the more so when we consider that these were cases in dispensary practice, where with the severe the very mildest cases may be seen. Duval and Bassett examined 25 successive cases and found the organism in 19, but it should be stated that the patients were observed in a sanatorium at a distance from Baltimore where, of course, only the more severe cases were sent from the dispensaries, while ours were all ambulant patients and their stools were examined whenever there was the slightest sign of any digestive disturbance. Our cases were also seen very early whereas, in hospitals, the cases are rarely seen until their initial symptoms have passed.
2. All types of diarrheal disease, as characterized by their clinical symptoms, are to be found among these cases. Some were examples of severe and some of mild ileocolitis; others could only be classed as the mildest form of intestinal indigestion. The course of the disease, while usually short, was prolonged in eight cases.
3. As compared with cases of "summer diarrhea" of other years those in this series were in general much milder; and possibly this was due to two factors: the cool summer and the increasing knowledge among the tenement population of the care of infants and their food.
4. The striking number of breast-fed infants, 14 in 62 cases, more than 20 per cent. of all.

In the series of Duval and Bassett previously mentioned, there were 4 breast-fed cases and a few others in addition have been reported. The great number in our series is accounted for by the fact that all stools from patients with diarrhea were examined. As will be remembered of our 14 breast-fed children, not one was severely or even moderately ill, and only one had blood in the stools. Such cases would therefore not be sent to hospitals, and so usually their stools would not be available for examination.

5. The serum treatment was not given in a sufficient number of cases to warrant any conclusions. While of apparent benefit in some cases, there were others in which no effect whatever was noticed. It may be that larger dosage is necessary; but, if so, the serum must be more concentrated than at present.

27. **Septal Distortion.**—Quimby's theory of septal distortion is that it is due to defective development of the jaws and teeth. Children with irregular teeth, high palatine, or narrow alveolar arch and distorted nasal septum should be treated by the dentist and rhinologist together. Of course this is not to be done till after ossification or after puberty; before this time the teeth are seldom sufficiently developed to make a satisfactory final regulation. If they are of a triangular variety, the earlier work should be especially directed to the correction of the nasal defect, and the regulation of the teeth left for some years later. A case is reported which he thinks illustrates the truth of this theory. The bending of the septum, he concludes, was due to imperfect articulation and undue vertical pressure from the developing maxillary bones, the pressure being relieved by separation of the maxillæ. The cartilage was pressed into the groove thus formed and the condition relieved.

28. **Gonorrhea.**—After a review of the literature Bierhoff gives an account of his experience with the modification of Lewin and Frank's method for the abortive treatment of gonorrhea with protargol injections. He has employed the method in 30 cases. In 50 per cent. the result was positive and in 15 negative. In the positive cases the gonorrhea had distinctly disappeared in 12 on the second day, in one on the third, in 2 on the fourth. Of the negative cases the gonorrhea had definitely disappeared in 2 after the fifth day (and thus might perhaps be included among the positive), in 3 cases after the tenth day, in one after the sixteenth day, in 2 after the twenty-first day and in one each after the twenty-second, thirty-fifth,

thirty-sixth and fortieth day respectively. One case is still under treatment. That a posterior urethritis developed in only 2 of the series, he thinks is the best argument for the utility of the abortive treatment.

30. **Ocular Signs of Syphilis.**—Reber reviews the different ocular lesions that may occur. A syphilitic primary sore is likely to be at the margin or just within the margin of the lids. It may be due to infection carried by the finger, as frequently occurs, or from the use of the tongue for the removal of a foreign body which is a common practice among the lower classes. Secondary syphilis may infect the cornea, uveal tract, *optic nerve or retina, but has a marked predilection* for the uveal tract. Every iritis is open to the suspicion of being syphilitic until other causes are demonstrated. Choroiditis is perhaps as frequently syphilitic in origin as iritis. It almost always leaves a scar in the choroid that may be studied years afterwards. Iritis, on the other hand, may leave no traces if successfully treated. The optic nerve is as likely to be tertiary as secondary in its involvement. Most frequently involved in the tertiary processes, however, are the intra- and extra-ocular muscles. Finally, tertiary lesions may appear in the lacrimal sac as extensions of similar lesions in the nose and accessory sinuses, and also in the lids as ulcers or broken-down gummas. Gumma of the iris is somewhat rare, but sometimes offers a classic picture of this phase of syphilis. Hereditary syphilis commonly affects the cornea in childhood and young adult life, though the ocular muscles are also sometimes hereditarily involved. Interstitial keratitis is the form usually assumed. The flat nose, bluish-gray white corneas, mouths with scarred corners, depressed cheek bones and imperfect teeth make a clinical picture which should be easily recognized. Deafness is frequently an accompaniment of the ocular lesions. Since syphilis generally attacks the eye savagely, the patient calls for treatment early and the results are, therefore, usually very gratifying. The form of mercury will be determined by the practice of the ophthalmologist, and Reber is convinced that one thing is certain, namely, that the pilocarpin or sweat cure tremendously assists the efficiency of whatever antisyphilitic remedies are used.

31. **Nervous Syphilis.**—Peter describes the lesions of the central nervous system, in immediate syphilitic infection, summing up briefly that the brain symptoms are multiple and variable in character, and not systematically grouped. Among them are paralysis of the cranial nerves, Argyll-Robertson pupils, irregularity of pupillary margin, inequality of pupils, apoplectiform and epileptiform attacks, recurrent palsies usually without loss of consciousness, numbness in extremities, increased reflexes, headache, vertigo, somnolence and altered mental states. These are signs which point to syphilis of the brain and its coverings. Syphilis of the cord is also distinct in its symptomatology. The essential point is the widespread involvement of the entire cord. There is a distinct group of symptoms, first described by Erb, characterized by a slow oncoming spastic paraplegia, atrophic at times, muscle contractures with bladder involvement, slight disturbance of sensation and a tendency to improve and then relapse. The essential point is the involvement of the entire cord, more extensive in some regions than others, giving rise to complete loss of function in certain parts and preservation in others.

33. **New Stain for the Diphtheria Bacillus.**—Andrade finds the following a good way of staining which he thinks has advantages. It decolorizes all other bacilli with the exception of the yeast cells and some large non-identified cocci, the bacilli of diphtheria appearing as a pale blue rod with deep reddish-brown granules in the almost colorless field. He uses Borrel's blue, 1 c.c., in 50 c.c. of a watery solution of vesuvin, 1/100,000. The method of staining is as follows: Prepare the films in the usual way. 1, Borrel's blue, five minutes; 2, wash in distilled water; 3, Lugol's iodin solution, one minute; 4, wash in distilled water; 5, decolorize in absolute alcohol until no more blue is given off; 6, wash in distilled water, dry and mount. The smears should be thin and easily spread. The best results are obtained with cultures from eighteen to twenty-two hours old, grown at 37 C.

38 *Recent Investigation of Certain Diseases Associated with Bacteriemia: Typhoid Fever, Pneumonia, Scarlet Fever, etc. Ludvig Hektoen.
39 Resection of the Elbow—Osteotomy for an Old Pott's Fracture with Deformity—Cyst of the Thyrolingual Duct—Ovarian Cyst and Pus Tube. J. H. Dunn.

38. **Bacteriemia.**—Hektoen describes the condition of bacteriemia in three diseases, especially in typhoid where the presence of bacilli in the blood is one of the most valuable diagnostic symptoms. The fact that typhoid bacilli are quickly killed by the human blood and that typhoid bacilli increase in this disease in this medium is explained by him as possibly due to the typhoid bacillus neutralizing, by the production of its destruction, the complement in the blood serum. He also suggests from the evidence that there is really a difference in the biology of the organisms of paratyphoid and typhoid fever. Pneumococcemia in pneumonia is also discussed. It is a constant and characteristic feature. He emphasizes the facts that pneumococci are demonstrable in the blood in certain cases before the primary symptoms can be detected, and that the subcutaneous or intraperitoneal injection of pneumococci into rabbits may give rise to foci in the lungs resembling lesions of lobar pneumonia, and that injection of pneumococci into the bronchi causes a rapid absorption of cocci into the blood. The destruction of pneumococci, he thinks, is largely due to leucocytes, since the blood serum itself is without destructive effect and high leucocytosis is indicative of a favorable prognosis. The leucocytes seem to exert a defensive rôle in pneumonia, and it seems that alcohol and ether have a paralyzing effect on them, as shown in rabbits. The last disease mentioned is scarlet fever, in which the streptococci are in the majority of cases demonstrated in the blood. Whether they are the cause of scarlet fever or not, it may be said that there is a very general invasion of the body in fatal cases. In practically all the cases of scarlet fever there is a great increase in the number of streptococci in the blood. Against the theory of their being the essential germs may be cited the absence of any general invasion of the body by the streptocccoci in the so-called foudroyant cases of scarlet fever. Furthermore, it is impossible to differentiate the streptococci which occur in scarlet fever from other familiar streptococci, and while one attack of scarlet fever gives rise to a lasting immunity, there is no evidence that an attack of scarlet fever produces any immunity to streptococcal infection. Moreover, in smallpox, diphtheria and measles there is also frequent streptococcal invasion in the blood, yet these diseases can not be said to be due to streptococci. He thinks it reasonable to conclude that while in the cases of the majority of children dying from scarlet fever the death is due to streptococcal infection, there is still no strong evidence of a direct etiologic relationship between scarlet fever and streptococci, even though the latter are of such paramount importance in the disease. There is a great need of an efficient antistreptococcic serum. He also makes the suggestion that there is possibly too little care exercised against the diffusion of streptococci in scarlet fever cases in the hospitals, severe cases being placed alongside the mild ones and the chance of further streptococcic invasion in the latter being thus favored.

40 Cystitis. J. Henry Dowd.
41 *Modern Management of Inflammation of the Middle-ear and Contiguous Structures. F. Park Lewis.

41. **Middle-Ear Diseases.**—Lewis describes the methods of treatment of middle-ear disease. He advises that paracentesis should be free, the use of local treatment with cocain and

adrenalin in the early stages before suppuration has commenced, drainage in chronic cases, and the usefulness of limiting the food supply in some early cases to abort acute mastoiditis. The last is strongly suggested by his success in one case in connection with other measures, such as cleansing of the ear and filling the meatus with protargol solution. The conclusions are that every otitis demands careful individual attention and close observation. In a large number of the cases judicious local treatment will render operation unnecessary, but when it is required it should be done early enough to prevent involvements which may prove fatal, and it should be done thoroughly. The main vital structures of the body are involved, and abnormalities of formation are common. It should never be undertaken except by those who have had experience either on the cadaver or have familiarized themselves thoroughly with the bony anatomy and the technic of the operation.

48 Bougie in Abdominal Cavity for Five Days. E. E. Haynes.

45. **Exophthalmic Goiter.**—Posert opposes surgical treatment as the statistics do not show any more favorable results than with medical treatment. As we do not know which theory of the disease is correct, it is hard to decide between excision and operation on the cervical sympathetic, and the danger of anesthesia is to be considered. Under cocain the operation is bloody and the possibility of fatal hemorrhage is to be considered. A scar is also left and a skillful operator must also be at command, therefore, surgical treatment should not be resorted to until other means have failed. The method he prefers is the use of faradic electricity. It is a nerve stimulant, produces a better blood supply, promotes metabolism and prevents the rapid proliferation of connective tissue which strangles the cells and inhibits the natural function. Nine cases were under his care, of whom five recovered, one died from intercurrent disease and three others have been lost sight of.

47. **Intestinal Parasites.**—Raines reports a case in an infant of twenty months who, in two weeks, passed 1,992 round worms, ranging from one to nine inches in length. The medication was santonin and calomel, followed by castor oil, and a salt enema. The mother, a mulatto, stated that the child had sneezed out a worm while at table one day, the first one seen.

49. **Oysters and Sewage.**—The state of Rhode Island has leased 3,000 acres of water for oyster cultivation in the Providence River and Narragansett Bay. Fuller has investigated the water there as to the bacteria and finds that the sewage contamination extends for six and a half miles down from Providence on the river. It does not exist in Narragansett Bay, but as the river has more oyster beds than all the remaining Rhode Island rivers, the importance of this sewage pollution is evident. Narragansett Bay proper is not polluted by the sewage of either Providence or Fall River.

54 *Some Additional Cases of Blastomycetic Dermatitis. T. Caspar Gilchrist.
55 Case of Lymphatic Leukemia with Purpura. Frederick C. Shattuck.
56 *Removal of Warts, Moles and Other Facial Blemishes. Geo. T. Jackson.

54. **Blastomycetic Dermatitis.**—Gilchrist reports several new cases, quoting one from McCarrison, published first in the *Indian Medical Gazette*, which is of interest as giving a new locality for the disorder. As far as the treatment is concerned, the administration of potassium iodid internally as suggested by Bevan, as well as exposure to the *x*-rays until a mild burn is produced, will, he thinks, cure the condition except in severe systemic cases. He remarks on its wide distribution, cases having been recorded in Germany, France, Italy, England, South America, India, as well as over 40 cases in this country. Another point of importance is the confirmation of Hektoen's observation that the blood of a patient suffering from this disease will agglutinate the blastomycetes.

56. **Warts and Moles.**—Jackson describes the methods of getting rid of facial deformities and warts. The ordinary wart is not common on the face. In elderly persons the senile wart may appear and may turn into an epithelioma. The best treatment for the seed warts when practicable is to scrape them off with a curette, a few at a time, touching the surfaces left with pure carbolic acid. Where this is not practicable the best method is to apply to the tumor a saturated solution of salicylic acid with collodion. By repeated applications it will come off. It must be remembered that these things disappear of themselves in time, and nothing should be done that will leave a scar. Filiform warts should be snipped off with a clean pair of scissors, and the base touched with pure carbolic acid. Senile warts may be removed with saturated salicylic acid solution, but if they show any tendency to enlarge they should be treated as if they were an epithelioma, thoroughly curetted and the base cauterized with nitrate of silver or treated with arsenical paste or chlorid of zinc. The tendency to become malignant must be kept in mind, and any trifling treatment is worse than nothing. Nevi appear in various forms, as the common vascular nevi or telangiectasis, port-wine marks and spider cancers, or they may take the form of vascular tumors. Pigmented nevi are sometimes spoken of as permanent freckles, and often long fine or coarse hairs will be found growing in them, forming the hairy nevus. Fibrous nevus is a fibroma, and varies from a small French pea to a small marble in size. To remove vascular nevi of all kinds nothing is so good as liquid air. One or two freezing applications with this agent carries them off, though it may cause a great deal of pain. Electrolysis is another reliable agent. In simple telangiectases the vessels may be destroyed by passing a fine steel brooch into their course and using a current of about 2 milliamperes for half a minute. In so-called spider cancer the best plan is to pass a fine cambric needle into the middle of the prominent point and turn on a current of two milliamperes for a minute to destroy them. A red-hot needle or a drop of fuming nitric acid will do the same, but may leave a scar. In children they may disappear, and it is well to wait for a while. Painting the parts with collodion will perhaps do some good. Where pressure can be made, a bandage may be used, but the danger of producing sloughing must be considered. Port-wine marks are very satisfactorily treated with galvanism, but the treatment is a little tedious, and fuming nitric acid, the acid nitrate of mercury or ethylate of sodium may be employed, applied with a sharpened stick wound with absorbent cotton, in a series of dots. Cavernous angioma may be possibly destroyed by electrolysis, or if that can not be used, by touching them with fuming nitric acid or puncturing with a red-hot awl, allowing it to cool on the spot. Pigmentary nevi may be destroyed by electrolysis of fuming nitric acid, which will give more satisfactory results in the larger ones. Pure carbolic acid will remove some of those of a light-brown color; glacial acetic acid will remove these nevi. Hairy nevi are satisfactorily removed only by electrolysis. It should be used as in removing superfluous hairs, and if these occur they should be destroyed before the underlying nevus is attacked. Fibrous nevi can, of course, be cut off, but electrolysis will be more painless and equally effective. Freckles resemble pigmentary moles, but are not permanent. Jackson's favorite prescription for preventing freckles is calamin 1.3, zinc oxid 4, glycerin 8, aqua calcis 24, aquæ rosæ ad 120. The face should be kept covered with this lotion when out of doors. There is little use

of removing freckles, for they return. They may be blistered out or faded out with peroxid of hydrogen. Usually brides apply for this treatment. Xanthoma, another facial blemish, is a yellow patch which comes on the eyelids. Electrolysis is the best agent for its removal. In conclusion, Jackson speaks of the removal of hairs and claims that the electrolytic treatment, if done by an experienced hand, is perfectly successful. Radiotherapy has been proposed, but is still on trial.

57 *Is the Usual Treatment of Post-partum Hemorrhage Correct? W. Gaston McFadden.
58 Insomnia. Eliot Gorton.
59 Berlin as a Post-graduate Center. C. R. Schaeffer.

57. **Post-Partum Hemorrhage.**—McFadden opposes the teaching that it is necessary to remove the clot in cases of post-partum hemorrhage. He says let us consider the physical conditions. We have a large coagulum formed, assuming the general contour of the surrounding walls, perhaps slightly pressing against them. You introduce the syringe with a long flexible catheter attached, and press it up to near the fundus, keeping the point of the catheter in contact with the uterine wall, just as you do in introducing the blade of your forceps. The syringe should be filled with Monsel's solution, and as you press it out it will trickle down the concavity of the uterine walls and will be kept in close contact with them by the retained coagula, the removal of which would disturb the open sinuses and increase the flow of blood. He would encourage the formation of coagulation rather than remove the clot, using merely very gentle pressure on the fundus until the uterus shows no further disposition to dilate and the mouths of the bleeding sinuses are closed. Then after the inertia of the organ passes away it will resume its normal physiologic function of contraction and expel the clot by its own restored muscle force.

60 The Best Method in the Treatment of Tuberculosis. W. A. Dickey.
61 Epileptic Automatism, with Report of a Case. Charles J. Aldrich.
62 *Echinacea—Some of Its Uses. W. F. Shumaker.
63 Measles. W. H. Baldwin.
64 Mesogastrium—from Personal Autopsic Abdominal Inspection in 400 Males, 150 Females and 60 Children. Byron Robinson.

62. **Echinacea.**—Shumaker gives the results of administration of this drug, the modus operandi of which he can not explain, the preparation being the fluid extract of the root—dose ¼ to ½ fluid dram—or specific echinacea—dose 5 to 30 drops. He finds that the glandular system seems to be stimulated, the stomach improved in its functions, the appetite increased, while the bowels operate better and the nutrition is improved. He thinks the drug stimulates the retrograde metabolism better than any single remedy known. He has used it in infants a few days old, and at every age without any bad results. He thinks it specially valuable in typhoid fever, in which it can be given without interruption from the start with any kind of temperature. In smallpox it relieves the itching and shortens the febrile period, and also modifies pustulation. In anthrax it prevents the formation of new colonies or boils and causes subsidence to a certain extent of those already existing. The dose should be large and repeated every hour until twenty-four or thirty-six doses have been taken. If any of the abscesses have an opening, the remedy should be applied locally in the strength of 1 part to 3 parts of boiled water. As a remedy for burns it has no equal, and less cicatricial tissue follows its use than with any other remedy. He uses echinacea 1 part, boiled water 2 to 6 parts, locally applied, keeping this up until the healing process separates the saturated gauze from contact with the part. In senile gangrene his confidence in its usefulness has been built up on the results of its use in less than a dozen cases. It stops sloughing and encourages the line of demarcation. In snake bite he has had no experience with it, but where rattlesnake bites are frequent, many cases are reported by those whose integrity he can not doubt, testifying to its value.

70 Nitrous Oxid and Ether Sequence. L. S. Chamberlain.

67. **Loco Diseases.**—Sayre is the dean of the school of pharmacy in the University of Kansas, and has chemically analyzed the *Astragalus molissimus*, the weed to which is generally attributed the so-called loco disease in cattle and horses. He finds no constituent in it which accounts for the condition, but does think that much may be due to fine irregular hairs which grow on the surface of the leaves. He has extracted a new crystalline substance, but this has shown as yet no toxic activity, and another from a fresh plant, which seemed to be neutral, but has an acid reaction toward some of the bases. This, however, has as yet been obtained in too small quantities to be tested physiologically.

75 Remarks on Syphilis of the Nervous System. Hugh T. Patrick.
76 *Practical Clinical Notes on the Administration and Action of Iodonucleoid, or Organic Iodin. G. Frank Lydston.
77 *The Serum Treatment of Hay Fever. Lewis S. Somers.
78 The Anterior Fontanelle. J. R. Clemens.
79 *Graves' Disease and Its Relation to the Psychoses. Arthur W. Rogers.
80 *The Prevention of Heart Disease. Robert H. Babcock.

71. **Epilepsy.**—In this first communication Kiernan discusses the pathology of epilepsy, the portions of the brain involved and the causes of convulsions. The great elements in epilepsy are the cerebral irritability, the excitability and the autotoxic state that exists. Elimination is checked, toxic material accumulates and the convulsive centers are excited. Epileptic instability is essentially the lack of balance of the degenerate or hereditary defective, plus, not rarely, a higher ethical and intellectual background.

72. **Acid-Fast Bacilli.**—Acid-fast bacilli, both the pathogenic and other kinds, and their literature are reviewed by Rosenberger, who reports experiments made with three-weeks' old cultures of the organisms. He states his conclusions that in doubtful cases in which acid-fast bacilli are encountered, a diagnosis of tubercle bacilli can be positively made by after-treatment of the stained spread with sweet spirits of niter or glacial acetic acid, which completely decolorize other acid-fast organisms than the tubercle bacillus, such as the grass and butter smegma bacilli. Where only a few organisms are found inoculation experiments should be made.

74.—This article appeared elsewhere. See The Journal of March 19.

76. **Iodonucleoids.**—Lydston concludes that this is a non-irritating and thoroughly assimilable preparation of iodin, less likely to produce iodism from a given quantity of the contained iodin than any of the iodin salts he has used.

77. **Hay Fever.**—First referring to Dunbar's serum, Somers gives his own experience with a serum made from animals inoculated with the pollen of golden rod, and employed both as a serum and as a powder. He finds that it produces a prompt and positive amelioration of the symptoms of fall hay fever in the majority of cases, and in a smaller number this favorable result is soon accompanied by the complete disappearance of the affection. Where there is little or no action after its use, pollen evidently does not predominate as an etiologic factor, but whenever results are obtained they are favorable. While he can not speak from personal experience on the effect of this serum on hay fever occurring at other

times of the year than the fall or when given in advance of the attack, it is certainly decidedly palliative, irrespective of the severity of the attack. Its effects on future attacks remain as yet unknown. Larger experience may modify some of these statements.

79. **Graves' Disease.**—Rogers claims from observation of 13 cases in the Milwaukee Sanatorium, that while there is no characteristic psychosis, his experience coincides with that of the great majority, that in three-fourths of the cases the maniacal types are found. The physical symptoms of the disease are not modified by the mental condition. He also holds that Graves' disease is indicative of a neurotic temperament and the mental and physical symptoms are both evidence of the same defect. The insanity is a further development of a neurotic and hysterical condition observed in even the mildest cases. Graves' disease as a rule does not make the prognosis of the insanity any less favorable.

80.—See abstract in The Journal, xli, p. 1040.

January.

81 *Mitosis in Circulating Blood. George Dock.
82 Case of Infection with Bacillus Pyocyaneus with the Primary Focus in Decubitus and with Special Reference to the Hemolytic Action of the Organism. Frances N. Boynton.
83 Pelvic Inflammation from the Standpoint of the General Practitioner. Reuben Peterson.

81. **Mitosis in the Circulating Blood.**—After first giving a résumé of the literature, Dock reports his own observations. The material included 20 cases of myelogenic leukemia, 3 of chronic, small-celled leukemia, 2 of acute leukemia, 2 of fatal megaloblastic anemia, 40 cases of chronic pernicious anemia and several hundred cases of secondary anemias, chlorosis and leucocytosis. Mitotic figures were found in both cases of acute anemia, in 2 of chronic pernicious anemia, in 1 of severe anemia with splenomegaly in an infant, not rachitic, but possibly syphilitic, in 8 cases of myelogenous leukemia and in 1 case of acute leukemia. Most of his examinations were made on preparations fixed in ether and alcohol and stained with hematoxylin and eosin. In the mitoses of 7 cases of leukemia, in severe anemia and in 3 cases of leukemia only the red cells were involved. He has never encountered a lymphocyte undergoing mitosis in the blood nor has he ever seen it in polymorphonuclear leucocytes. The occurrence of mitotic figures in normoblasts has rarely been noticed by previous writers, but in leukemia many of the most unmistakable figures were in cells, not much above the average size. Some years ago he expressed the opinion that mitoses are more frequently found in white than in red cells in leukemia, but a larger experience has made him reverse this opinion. The number of mitotic figures varies much in different cases, and in the same case at different times, and the phases of mitosis offer some interesting facts. The preparatory phase in which the chromatin shows a coarse meshwork, is strongly suggested by many nucleated red cells, especially certain megaloblasts. The earliest appearance that can be positively identified is the spirem with rather coarse skein, which has been rare in his preparations. The metaphase is rather more frequent, but the commonest figure by far in red cells and leucocytes is the diaster without signs of division of the cell body. In trying to discover the significance of the presence of mitotic processes in circulating blood, he has examined the associated conditions. The mitotic red cells in leukemia are not encountered merely in cases of the greatest anemia, nor are they always met with in these cases. The facts on the whole seem to go far toward the explanation of the phenomenon. The presence of both the nucleated red cells and myelocytes indicates a defect in the blood-forming organs. The presence of mitoses in cells can easily be explained by assuming that cell formation is active and that some of the cells happen to migrate in some stage of division. In the case of nucleated red cells one is tempted to see a teleologic process and suppose that mitoses indicate active regeneration of the blood, but this can not easily be proven. At present Dock does not think we are justified in claiming that mitosis in the circulating blood has any definite diagnostic or prognostic value. The atypical mitosis is rather more serious in its indications than the normal process, but probably only because it is found with extremely active cell development and because this is often a part of unfavorable conditions.

90 The Present Status of the Profession in the Treatment of the Opium Habit. A. R. Williamson.

84. **Auto-intoxication.**—This article, which is a preliminary paper of a series, gives the history of the theory of auto-intoxication and considers the subject in general. The author gives the system of his classification, which will be followed in the subsequent papers: "1. Intestinal auto-intoxication: absorption autotoxicoses. 2. Catabolic auto-intoxication: retention autotoxicoses; autolysis; acidosis. Histolytic autotoxicoses; nucleolysis. Histoenzymic autotoxicoses. Combined retention—histolytic autotoxicoses."

87. **Typhoid Fever.**—Edwards describes the method of uterine anastomosis used in a case of resection from typhoid perforation. A bobbin formed of a coiled spiral with a thread through each end forms the support, which is extracted from the bowel at the close of the suture, by being unscrewed through the last stitch as a shirt stud is removed from a shirt. The substance he prefers is celluloid, though he sees no reason why hard rubber or leather might not also be used.

89. **Cardiac Failure.**—Eisendrath had experience with a number of cases at the time of the late Iroquois Theater fire in which he used the methods of resuscitation described in cases of cardiac failure in some of which asphyxia was apparently complete. One of the methods mentioned is the use of adrenalin; another that of Koenig, consisting in making on the precordial region a number of sharp pounding or pressure movements. He has tried this method in nine cases in cardiac syncope from chloroform. The technic consists in making 120 movements per minute over the precordial region. A modification which might be tried in extreme cases is that of resecting the fourth and fifth costal cartilages and taking hold of the heart, using direct massage. He also refers to an English surgeon's method of direct massage through the diaphragm. The second method was the one proposed by Laborde, making rhythmic traction on the tongue 16 to 18 times per minute, bringing it out as far as you can each time. The third method was the administration of adrenalin solution as suggested by Crile. A boy was brought into the hospital with a crushing injury of both legs and in a severe condition of shock. He was given 5 minims of a 1-1,000 solution of adrenalin hypodermically and then 1 minim of the 1-1,000 solution every hour for five hours. Transfusion was also employed. He improved and made a rapid recovery.

1. **Cardiac Rhythm.**—This paper seeks to explain a special form of cardiac irregularity where the heart is at no time regular and two beats of the same character do not follow each other. This has been known under the names of delirium cordis, mitral pulse, pulsatio irregularis perpetua, etc. Mackenzie's explanation of the condition is that it is due to the ventricles taking on the inception of the rhythm instead of it beginning with the large veins as they enter into the auricles, as is normally the case. Whenever there is a continuous irregularity as distinct from occasional or rhythmic irregularity, the ventricle is giving the rhythm. The cause is to be sought in the irritability of the heart muscles and not in a disorder of its nervous regulation. The exceptions to this are rare. Hering's experiments demonstrate that a rising ventricular pressure can produce premature contraction of the ventricle apart from its nervous connections. Mackenzie has had several opportunities of noticing the beginning of symptoms associated with attacks of continuous irregularity and is convinced that dilatation and ineffective action of the heart is secondary. When irregularity begins there is an uneasiness in the chest, shortness of breath and an increasing sense of weakness. Coincident with these are definite changes in the circulation, the radial pulse becomes larger and compressible, the veins of the neck are engorged, the face dull and dusky and the lips blue. The area of the heart's dullness extends beyond the right of the sternum and the superficial structures of the chest wall become tender to pressure, as he has noticed in dilatation of the heart. These symptoms are those met in advanced cases, and he suggests that it is the irregularity that is the cause of the inefficient heart's action for this reason and not dilatation that causes the irregularity. The treatment should be directed to the lessening of the irritability of the heart muscle and to protect it from being exposed to the causes that increase its activity. The best remedy he finds is prolonged rest in bed.

2. **Hemoglobin Investigation.**—Schott has used the Dare hemoglobinometer and reports cases showing the effect of the Schott treatment, not merely on the heart diseases, but on the general condition of the body as well, including increase of the hemoglobin percentage.

3. **Diabetes.**—The researches of Mossé published two years ago show that potatoes are often well borne in diabetic glycosuria and are capable of being substituted for wheat and bread in proportions enough to keep up the alimentary ratio. To the potash salts Mossé attributes the superiority of the potato diet. Sawyer's experience has confirmed these findings and he points out that to retain the potash salts in cooking potatoes should be steamed with the skins on. He also suggests the use of potato flour in bread, cake, etc., for diabetics, and gives the following prescription:

Bran and potato bread. Take half a pound of flour of steamed potatoes, quarter of a pound of bran, half an ounce of German yeast, half an ounce of butter, one egg. Twenty-four hours before making the dough cook the potatoes by steaming them *in their jackets, then peel and break up into flour with the fingers.* Mix all the ingredients together. and let the paste stand near the fire for an hour to rise. Bake in greased tins for an hour *and a* half.

He also lays *down a diet for diabetics as follows:*

May Eat.—Butcher's meat of all kinds, except liver. Pork, ham, bacon, poultry, game, potatoes steamed in their skins, fish, oysters, crabs, lobsters. Animal soups, not thickened except by potatoes. Mutton broth, beef-tea. *Bran and potat*[illegible] potato [illegible] and cakes, eggs, cream, butter, cheese, greens [illegible] cress, lettuce, mushrooms, nuts, jelly or [illegible]

May Not Eat.—Any bread or biscuits but those made of bran and potato. Sugar, asparagus, broccoli, cauliflower, carrots, parsnips, French beans, peas, turnips, arrowroot, macaroni, rice, sago, *tapioca, vermicelli, pastry excepting potato* cakes, puddings, fresh and preserved fruit.

May Drink.—Water, tea, coffee, soda-water, claret, *hock*, spirits and water unsweetened, bitter ale (very sparingly), milk (very sparingly).

May Not Drink.—Cocoa, chocolate, champagne, porter, stout, home made wines, liqueurs, cider, sweet wines, ale.

5. **Veronal.**—Jordan thinks veronal is a useful means of producing sleep in doses of 4 to 5 grains. Larger doses may be re-

quired in severe mental excitement, etc. He says that no remote after-effects of any kind have been observed, that immunity from the bad effects on the vital organs is the chief recommendation, and that there does not seem to be a probability of creating veronal habit.

6. **Oxygen in Cystoscopy.**—Faulds prefers the use of oxygen gas for dilating the bladder because he thinks it has a beneficial effect on the accompanying cystitis and a clarifying action on the urine. It should be used with great caution. The patient should be warm and comfortable and the gas should be pure. The gas must enter the bladder slowly and with great care. If cystitis exists it will be necessary to use a local anesthetic. Oxygen can be left in the bladder without disadvantage and often to the patient's benefit.

7. **Aseptic Surgery.**—Lockwood's third lecture treats of the accurate closure of wounds, drainage, dressings and the influence of environment in operation. He speaks highly of the use of transplanted skin flaps as doing away with the necessity of skin grafts, being better in some respects in its results. Drainage, he thinks, is unnecessary, excepting in infected wounds, though in certain operations, like those on the gall bladder and rectum, it is indispensible. The essential qualities of the dressing are sterility and dryness. He still uses the outer Listerian dressing, which has been largely abandoned in general practice. He finds it specially useful in the radical cure of hernia and in cases of laparotomy when vomiting is likely to occur. In hot weather it can be dispensed with after the first forty-eight hours. The lecture is largely taken up with the effects of different environments on the prognosis of surgical wounds and is illustrated with a number of cases.

8. **Muscular Structures of the Heart.**—Keith describes the support of the heart in the thorax, the effects of its changes during systole and diastole, and the manner in which different parts of the heart work.

9. **Head Injuries.**—English discusses late traumatic abscesses and traumatic epilepsy. He thinks the operative treatment of epilepsy is not curative, but may be palliative for several years; for this reason operation is not to be discarded. Suitable cases are those in which there is evidence of injury, or the epilepsy is jacksonian with localized convulsions, or the disease has not lasted for more than two years, and there is no neurotic family history. With general convulsions the chances are slight. There are cases in which the relief from fits has lasted for many years, but these are rare, for it is usual for them to return in two or three years. Traumatic insanity is also discussed at some length and the author offers the following conclusions:

> 1. While some degree of mental impairment is comparatively common after injuries to the head the changes are seldom sufficiently marked to be included under the heading of insanity. 2. Insanity may result from injury to any part of the head. 3. Traumatism leads to insanity in two ways: Direct insanity due to the actual injury to the brain or its membranes apart from hereditary or other predisposing causes, and indirect insanity—that is to say, any form of insanity occurring as the result of lowered resistance of the brain due to injury in patients with a predisposition to insanity, hereditary or otherwise. 4. Every variety of mental change may be produced by traumatism, although some forms are commoner than others. 5. It is at present undetermined whether injury to the prefrontal region is more likely to be followed by mental disturbances than injury to other parts of the brain. 6. Only a small proportion of the cases of traumatic insanity are open to relief by operation, for a localizing indication in an accessible region must be present. 7. The results so far have been encouraging, and although the operation must necessarily be exploratory, it is fully justified in suitable cases, especially in face of the otherwise hopeless condition of these patients.

11. **Motor Symptoms in Mania and Melancholia.**—Stoddart holds that in mania an irritating product is formed within the cortical neurons and the frequency of hallucination in mania supports this view. In melancholia, on the other hand, a paralyzing product is formed, and in agitated melancholia there is a combination of deleterious influences—a paralyzing product in the neurons and an irritating body in the plasma which bathes the nerve cell. In a few cases of mania there is, in addition to the irritating body within the nerve cell an irritating body in the plasma. Whether we are to infer a new formation of cytotoxins or increased formation or deficient elimination of substances normally occurring, there is no evidence to show, but he thinks it is well to bear in mind that there is in melancholia a general tendency of the cells in the organism to fail in the excretion of their normal metabolic products. He thinks the delusions of melancholia arise from a feeling of inactivity in the stimulating cortical neurons.

13. **Filaria Perstans.**—Bastian holds that we know very little about the internal anatomy of the *Filaria perstans* and are unable to properly refer it to its true taxonomic position. It is an error, he thinks, to say that nematoids pass through one or more metamorphoses, since so far as known they attain maturity by steady and progressive development. They stand in no need of being harbored by intermediate hosts, but have independent existence from their emergence from the egg, and plants and vegetables in use as well as water may be the real sources through which they attain entry into the human body, where they develop as facultative parasites.

14. **Congenital Hypertrophic Stenosis of the Pylorus.**—Cautley reports a case with certain features which seem to indicate to him that the affection may exist apart from the typical symptoms, that an apparently mild case can induce severe wasting, and that operative treatment is indicated, though food can pass through the pylorus. There is little doubt that the extent of the condition may vary in different cases, and the diagnosis and decision as to operation be very difficult. Mild cases may occur and the symptoms be limited to dyspepsia and occasional attacks of vomiting, but terminating in later life with dilatation of the stomach and hypertrophic stenosis of the pylorus.

15. **Smallpox.**—Nash thinks the red light treatment of smallpox is still a subject for investigation, but that there is some evidence in its favor.

16. **The Bacillus Coli.**—Eyre has investigated the intestines of a large number of animals, including fishes, and in all he found the *Bacillus coli* in abundance. He thinks that further study in this direction is indicated before assuming that the presence of the *Bacillus coli* is always synonomous with sewage contamination.

17. **Meniere's Disease.**—In the case reported by Parry the insertion of a seton in the neck produced marked alleviation of symptoms. He has looked over the literature and finds no cases where a seton has been tried in this condition. His case was a severe one and he believes a milder case would yield much more beneficial results.

18. **Alopecia Areata.**—Whitfield reports four cases of alopecia which had resisted treatment until relief followed attention to ocular defects. He thinks that in some cases nervous irritation consequent on undue effort to focus on fine objects causes the onset of the falling out of hairs in people whose health is not robust, and in any case inquiry into the condition of vision will do no harm.

21½ Symblepharon and Its Treatment; Two Cases Treated Successfully by Transplantation of Flaps of Mucous Membrane from the Mouth. Harry Gidney.

19. **Blood Examination.**—In an examination of 3,413 cases, parasites were found by Powell in 2,652. The great majority, 2,542, were malarial. In 94 cases relapsing fever spirilla were found. In 15 cases the plague bacillus and in 1, filaria nocturna. The leucocyte count was also found useful, giving a suspicion of pneumonia, internal abscess, filaria and other worms. He thinks it a safe estimate to say that nine-tenths of the cases of fever in Bombay, which last ten days or more, are due to either tubercle, enteric fever or abscess. His findings confirm Christopher's and Stephens' observations that the large mononuclear cells are always increased in malaria. If after a search of ten minutes no malaria parasite is seen, but the mononuclear cells seem increased, he continues his search, but if their percentage is low, he discontinues the search. In chicken-pox he finds the large mononuclears also increased, and in liver abscess he gets but little help from the blood examinations. Another point which he has formerly drawn attention to is the increase of eosinophiles in case of guinea worms. In 117 cases of plague the blood was examined, and in 15 of these the bacillus was found. In the beginning of the year there was a particular type of septic plague in which the rule was to find the bacillus in every field. The patients always died. He can also confirm Miss Corthorne's observation that the coagulability of the blood as a rule is diminished in plague. In relapsing fever there are many cases which never relapse, and are called malaria. It is only a systematic examination of the blood that determines the condition. He remarks as to the peculiar facies of spirillum fever cases, an ashy complexion, a quiet, sad, resigned, or docile expression which contrasts strongly with the dull, blear-eyed, obfuscated plague patient. Pneumonia is often difficult to diagnose, and he thinks there are cases of so-called *pneumonia* where the lungs are not involved. Where sunstroke is common, cases of fulminating pneumonia are also found. He asks if some of these cases of sunstroke might not be acute pneumococcus infections. Blood examinations were negative in the majority of cases of plague; also in many cases of pneumonia, tuberculosis, pleurisy, enteric fever and occasionally in venereal diseases, leprosy and liver abscess, smallpox, chicken-pox, etc. He has never seen anything suggestive of Malta fever in Bombay.

32. **Serum Treatment with Whey.**—Blondel ascribes remarkable therapeutic value to subcutaneous injections of what he calls "milk serum." The milk is quickly coagulated by adding an acid and then heating to 100.5 F. It is then neutralized with soda, cooled and filtered through a bougie. Daily subcutaneous injection of 20 c.c. of this serum produces no disturbances or inconveniences in a healthy man, but it evidently *stimulates metabolism*. In disease it reduces the temperature and lowers the blood pressure. These effects are constant and durable. The mechanism is not that of an antitoxin, but the "lacto-serum" acts by its re-enforcement of the *normal* processes of defense on the part of the organism against all toxins in general by its oxidases and the leucocytosis which it induces. He cites a number of instances to show its efficacy in various infections. In puerperal fever its action is most beneficent at the stage when the toxins have passed into the blood and the temperature remains high after curetting and disinfection of the uterus. Parallel cases illustrate best of all the advantages of this *milk-serum treatment*. *A little quinin given* with the serum seems to enhance its action in puerperal fever. In a severe case of erysipelas the temperature dropped from 40.5 C. to normal in five hours after injection of 10 c.c. of the lacto-serum. The local symptoms also gradually subsided to a complete cure by the sixth day.

33. **Tincture of Horse-Chestnut in Pelvic Affections.**—De Veney confirms by new experiences his previous announcements in regard to the peculiar efficiency of tincture of *horse-chestnut* for soothing the pain and reducing the size of hemorrhoids. He gives it in 10 drop doses before meals twice a day, *increasing gradually* by 10 to 15 drops a day, but with great care not to go beyond the dose needed by the individual subject. Too large a dose exaggerates instead of soothing the pains. In his experience this treatment has cured in a single day rebellious cases of hemorrhoids accompanied by rectitis with glairy stools, when the tincture was supplemented by equal parts of tincture of aloes or by a 1 cg. pill of silver nitrate morning and night. In case of indolent hemorrhoids due to habitual constipation, *he adds to the tincture equal parts* of tincture of nux vomica. He finds the horse-chestnut tincture also useful for external application as an adjuvant in some cases of hemorrhoids and varices, but its principal field is in reduction of congestions in the small pelvis. It acts by means of its influence on the sympathetic system, *modifying the* circulation throughout the small pelvis, and giving the internist another weapon against the so-called surgical affections of this region.

36. **Intoxication from Meat.**—Chevalier reviews the various symptoms characteristic of intoxication from diseased or rotten meat and botulism. Treatment should be symptomatic. If fifteen to twenty hours have elapsed, the stomach pump will probably be useless and a microbian infection is probably superposed on the intoxication. The intestines should be evacuated and disinfected. For the latter purpose he prefers beta naphthol, benzonaphthol, betol or salol, combined with pulverized charcoal. Bouchard has established that *the charcoal*

reduces the toxicity of substances in the intestine. The bile function should be stimulated with calomel and in severe cases the glycogenic functions of the liver may be stimulated with injections of ether. Diuresis should be maintained by drinking freely, especially lactosed milk, which is the most efficient diuretic in such cases. Warm drinks to promote sweating and tepid baths will also be found useful. Convulsions, etc., should be treated symptomatically.

38. **Red Treatment of Smallpox Among the Chinese.**—Regnault describes the methods of treatment of smallpox in China and Annam. The eruption is washed off with a lotion colored a brilliant red with some harmless vegetable dye. The parts are thus stained red. In Annam red curtains are also hung up around the bed. These red applications have been extolled for centuries as effectual in smallpox, which has been known and studied in China for three thousand years.

43. **Neurasthenia of Dyspeptic Origin.**—This article is taken from Robin's work on "Diseases of the Stomach." It treats of the particulars of gastric neurasthenia, the chemical conditions and the therapeutic conceptions of neurasthenia, summarizing in conclusion the indications for treatment and the means of realizing them. After curing the dyspepsia he first tries the glycerophosphates, magnesium or fluorids, sending the patient into the country. If this fails, he tries iron and arsenic, supplemented by strychnin, hypophosphites or phosphoric acid in dosage which he minutely details. If these fail, he abandons drugs and restricts all treatment to physicotherapy, hygiene and psychic measures. If all these fail, the Weir Mitchell treatment may be applied. He relates examples of the various forms of these "nervous echoes" of digestive disturbances.

44. **Auto-observation of Cocain Intoxication.**—Archambault's throat was sprayed with cocain for removal of a small polyp. Between 1 and 2 gm. of cocain were used and symptoms of acute intoxication developed afterward, first bulbar and then cortical, the two phases lasting a total "five hours of horror," as he describes it, barely escaping a fatal termination. He relates in detail the various subjective symptoms, the anesthesia of legs, arms and face, loss of the sense of space, an indescribable anguish with intolerable pains in the heart and stomach region. After three hours of repeated artificial respiration, the head low, sinapisms to the body with 2 c.c. of ether and 1.5 gm. of caffein subcutaneously, the cortical phase developed with violent excitement and exaggeration of the pains. He was unable to leave his bed for six days, but by the tenth day no traces were left of his intoxication experience. [A somewhat similar experience was related by a confrère at a recent meeting of the Berlin Internal Medicine Society, February 15. A physician had swallowed inadvertently a cotton wad soaked with cocain which he had been applying to a papillomatous swelling in the nose. He drank at once some strong coffee and a quantity of brandy, but the excitement and distress were not relieved and the dyspnea became threatening. Artificial respiration had to be kept up until the respiration center could recuperate, and the physician in charge sent to the neighboring fire department for the life-savers. Three men responded to the call, bringing the oxygen apparatus, and as they had been drilled they raised and lowered the patient's arms, while the third squeezed the oxygen bulb at each inspiration. The patient was thus saved after several hours' work. Large amounts of grape sugar were found in his urine during the first three days and also paired glucuronic acid, the latter not vanishing until the seventh day. In both this and the case above the patients thought they were dying, and made arrangements for the funeral, etc. Archambault remarks that the reassurances of the physician are peculiarly needed in cocain intoxication.—Ed.]

52. **Digestive Tract in Pernicious Anemia.**—This article, as it appeared in Danish, was reviewed in The Journal, page 407.

53. **Involuntary Swallowing of Air by Dyspeptics.**—Mathieu has found that 5 to 6 per cent. of all cases of stomach affections in his experience present more or less marked aerophagia. The subjects are unconscious of it and merely complain of the eructation of gases and more or less flatulence. He has established that frequently what they suppose to be an eructation is in reality an involuntary swallowing of air. The flame of a lighted candle held to the mouth does not blow out but remains immovable, showing that there is no emission of air. Sometimes the air is belched up as soon as it enters the stomach, sometimes it accumulates until the distension becomes marked and the air escapes into the intestine with a characteristic sound. One subject found that this swallowing of air occurred more than five thousand times during the day, but never at night or when he was absorbed in his business. The swallowed air may present the complete picture of severe gastrointestinal flatulence. He distinguishes between the aerophagia of nervous dyspepsia, the spastic aerophagia of severe neurasthenia and hysteria and the secondary aerophagia accompanying a severe gastric affection. He describes these forms in detail. As soon as the subjects can be convinced that their troubles are due to this cause they easily conquer it. The spasmodic swallowing can be controlled or prevented by keeping the mouth open, using something to serve as a gag if necessary. The underlying dyspepsia must be treated, and another indication is for measures to reduce the excitability of the stomach. He prefers for this codein and cherry laurel water, but morphin and other antispasmodics may be necessary in certain cases. The best means to abort an attack is a saturated solution of chloroform. He gives it in tablespoonfuls at the beginning and during an attack, mixed with water, to a maximum of 4 to 6 tablespoonfuls a day. Antiseptics for the intestines are not needed. The gaseous fermentations to which the flatulence was ascribed not existing in reality, measures against them are only liable to entail drug gastritis. Isolation may be necessary for severe neurotic cases. (Compare review of Stern's article on the subject, page 676.)

54. **Weber Test for Occult Stomach and Intestinal Hemorrhages.**—Hartmann concludes from his research and experience that occult bleeding never occurs in nervous stomach affections, but that it is liable to be artificially induced even in healthy subjects when the stomach content is siphoned out. He consequently prefers to examine the feces as the routine measure. He has found that the findings of the Weber test are reliable only when no meat has been ingested beforehand, not even well-cooked meat. When used with these precautions and the foresight required it is a very valuable and frequently a decisive means of clinical investigation, especially in case of round ulcer of the stomach. The occult hemorrhages occur in both benign and malignant conditions entailing insufficiency of the stomach functions. The probabilities are in favor of the existence of a carcinoma when the blood findings in the feces are constantly and decidedly positive with good motility, and absence of free HCl and of lactic acid, even when all other signs of cancer are lacking. The Weber test was described in The Journal, xli, p. 1566, paragraph 92. Hartmann's experience is the result of the systematic investigation of every case of a gastrointestinal affection at the Marien Hospital at Hamburg last winter.

58. **Ficker's Typhoid Diagnosticum.**—See editorial last week, p 775.

60. **Transmission of Tuberculosis from Man to Cattle.**—Ten cases of clinical tuberculosis are described in detail, the bacilli from which were inoculated into ten calves. In 2 of the cases the bacilli were not at all or very slightly virulent; in 3 weakly and in 5 extremely virulent. Among the 5 cases of apparently primary tuberculosis of the digestive tract in children, the bacilli in all but 1 displayed marked virulence. The only source for the primary tuberculous affection in the intestines which could be discovered in 2 cases was insufficiently sterilized milk. The parents were healthy and no cases of tuberculosis were known in the environment. In both cases the bacilli proved exceptionally virulent for the calves. Fibiger adds that he found evidences of tuberculosis in 116 out of 213 cadavers examined. They included 5 cases of unequivocal primary intestinal and mesenteric tuberculosis, 2 of probably primary tuberculous affections of the digestive tract and 8 of isolated tuberculosis of the mesenteric glands or lymphatics of the colon. This is a proportion of 6 per cent. of all the cadavers examined and of 11 per cent. of the cadavers with a known tuberculous history. The number of children's cadavers was 79, of which 25 were tuberculous, and in 4 the affection was in the digestive tract and evidently primary. This is a proportion of 5 or 6 per cent. of all the children cadavers and of 16 to 20 per cent. of all the tuberculous children. Heller and Wagener published last fall that they found 16 cases among 76 child cadavers, and 28 among 600 cadavers of all ages, the deaths due to various causes. Few are able to examine the digestive tract of child cadavers with Heller's painstaking technic, and consequently more careful examination might show an equally large percentage in others' material. Even as it is, the statistics that have been published show that primary tuberculosis of the intestines is not a rare affection.

61. **Is Tabes Due to Syphilis or to Some Social Factor?**—Rosenbach sharply criticises the statistics which Erb marshals to sustain his argument that syphilis is the main factor in the origin of tabes. Rosenbach mysteriously hints that they open quite *another perspective* for the pathogenesis of tabes than what Erb intends. (See page 620.)

62. **Hemolytic Property of Serum in Uremia.**—Senator has examined the blood of 3 uremic subjects in respect to the hemolytic property. The findings were contradictory. In his last case, which he describes in detail, there was no inhibition of hemolysis while it was marked in the others. He urges further study of the subject and refers to Micheli's recent statement that an antiautohemolytic action occurs exceptionally, independent of morbid changes, but seems to be more frequent in uremia than in other conditions.

64. **Ultramicroscopy.**—Among the interesting points noted by Rachlmann with the new "ultramicroscope" is that the action of bactericidal fluids can best be studied with this instrument. The cessation of movements among the bacteria occurred at a constant moment for given disinfectants and given strengths. The improvement consists in the focusing of the light on the field, and he found bright summer sunlight the best for the purpose. Chemical changes in fluids can be visually traced and certain physiologic processes divined from the findings. Turning a weak electric current into a fluid containing bacteria and albuminoids caused the entire swarm to rush to the positive pole, while they all returned to their original position as soon as the current was turned off, but not a trace of life could be detected in the fluid thereafter.

65. **Hemolysis by Cancer Extract.**—Kullmann's research on rabbits has demonstrated that an extract of cancer tissue is powerfully hemolytic.

66. **Routes of Tuberculous Infection in Child's Body.**—Westenhoeffer believes that Koch is right in attributing minor importance to tuberculous milk and meat as the source of tuberculosis in man, although Koch, he thinks, was mistaken in denying the identity of human and bovine tubercle bacilli. He also agrees with von Behring in ascribing to early infancy the inception of tuberculosis, but he does not regard it in the same light as the latter. His opinion is that the infant becomes infected during the period of the first dentition, when it is *putting everything it can reach in its mouth,* and the attendants give it what it can not reach, rub its gums, and test the warmth of the milk by touching the tongue to it or putting a finger in it. The inflamed condition of the gums favors infection. As the child cries and is restless, its rattle is picked up from the floor and given to it to bite on, etc. The child creeps on the floor and then sucks its thumb for hours. The mother feels of its gums just after she has been, perhaps, washing the handkerchiefs of her consumptive husband. He appeals that the profession must not wait for the child to be brought for medical advice, but the state, *community,* societies, the citizen and all who have raised the antituberculosis standard must go to the infant and surround him with hygienic care, transferring him to some other environment if necessary. He thinks that the infant's hands should be washed a hundred times a day if necessary, and nothing should be given back to it which has once fallen on the floor or, better *still, not give it anything to bite on.* These relations of the nursling to the family are the true source of tuberculosis; infection from cows is unimportant in comparison. He announced in the course of his remarks that the meat of cattle affected with tuberculosis never contains tubercle bacilli, with the sole exception of meat from cattle with generalized miliary tuberculosis.

74. **Orange-Colored Perspiration.**—Harz found a small, nonmotile bacillus accumulated thick on and in the hairs in the *axillæ* as the cause of the orange sweat. It had not caused

any disturbance except the coloring of the sweat, and consequent staining of the linen. He calls it the *Bact. auratum.*

76. **Tetanus Toxin in Tissues.**—The brain, liver, lungs, muscles and other organs from animals that have succumbed to tetanus are able to induce tetanus when injected into mice. This occurs irrespective of the amount of blood in the tissue scraps. The symptoms observed differ, however, in some respects from typical tetanus.

81. **The Negri Bodies in Rabies.**—Bertarelli found these bodies in the cadaver of a lad of 12 who had succumbed to hydrophobia. They were found exactly as described by Negri, but he does not think that the causal connection with the disease is yet established.

82. **Bacteriology of Milk Ducts in Bovines.**—Uhlmann found numbers of bacteria and streptococci in every section of the papillary duct of cows, goats and sheep. It is, therefore, impossible to obtain an absolutely germ-free milk from the domestic animals under any circumstances.

86. **Naphtha in Disinfection.**—Kupzis states that the alkaline by-products of Russian naphtha possess high disinfecting power. It diminishes in proportion as their boiling point rises.

95 Chemical Changes in Paralyzed and Degenerated Muscles. T. Rumpf, Gronover and Thom.—Weitere Untersuchungen über Polyneuritis und die chemischen Veränderungen gelähmter und degenerierter Muskeln.

89. **Study of Coagulation of Blood.**—Morawitz ascribes the coagulation of the blood to the concerted action of at least three substances, thrombogen, thrombo-kinase and the calcium salts. The first is found only in the blood and lymph, the second can be produced by all the tissues.

90. **Elimination of Water Through the Skin.**—Schwenkenbecker thinks that water evaporates through the skin outside of the secretion of the sweat glands. This cutaneous perspiration is a regulating process, but the amount averages as much as 28 gm. an hour for a young man of ordinary size on a moderate diet and at moderate work. He conducted experiments on a large number of subjects, the results of which are tabulated, and the technic described. He comments on the paucity of our present knowledge in regard to the water metabolism, which was his inspiration for the present monograph.

94. **Influence of Blood Pressure on Fluids in Tissues.**—Hess thinks that the variations in the blood pressure have a direct effect on the concentration of the blood only in the veins, not in the arteries. The concentration of the blood may differ in these two systems. This is soon compensated and regulated by the streaming of the blood into the arteries, and he ascribes to the lungs this regulating mechanism. The rôle of regulator is favored by the independent circulation in the lungs. He describes the mechanism as he understands it, and comments that this promptly functioning regulating arrangement enables the body to supply normally concentrated blood to the organs, even in case of extreme variations in the blood pressure. After loss of blood the organism aspirates lymph at once to substitute the missing quantity of blood, but the restoration of the concentration to normal is a more gradual procedure. He thinks these views explain the changes in the blood at high altitudes, and in case of uncompensated valvular defects. He urges comparative examination of blood taken from an artery and from a vein as liable to solve the problem of the changes observed in these conditions. He gives the particulars of research on 17 dogs, and emphasizes the importance of this regulating function which he has discovered in the lungs.

104. **Nose Obturator.**—Aufrecht's convenient little instrument for arresting bleeding from the nose consists of a long, narrow bag of thin rubber, somewhat smaller in diameter at the center. A stiff tube with numerous perforations is inside the rubber bag, and the whole is connected with a rubber bulb. The bag is introduced collapsed into the nose, and then inflated with the bulb.

106. ***Potassium Permanganate in Opium Poisoning.***—Moor's research explains the efficacy of subcutaneous injections of potassium permanganate in morphin poisoning. The permanganate combines with fluids containing albumin to form a powerfully oxidating substance, which is not altered by the blood and yet can give up its oxygen to morphin. No other alkaloid in his tests was oxidized in this way except quinin.

116. **Cancer and Soil.**—Hoeber is "police medical officer" at Augsburg, Germany, and presents a comprehensive study of the conditions which accompany cancer in that city of 84,097 inhabitants. The average death rate is 24.74 per 1,000, of which 5.5 per cent. are due to neoplasms. The number of fatal cancers in women is 65 per cent. to 35 per cent. in men. He gives a number of tables and maps showing the cancer houses, the soil and geological foundation, etc., and the coincidence of tuberculosis. He was unable to discover any connection between the occurrence of cancer and the height, drainage and other conditions of the houses. Both cancer and tuberculosis were most prevalent in the poorer quarters.

117. **Simultaneous Cancers of Different Kinds on One Subject.**—The coincidence of cancer in the stomach and glioma in the brain has been observed by von Hansemann in one case.

In another a glioma of the brain was accompanied by a cholesteatoma of the base of the brain. The latter case was the more remarkable as the first symptoms were observed after a fall from a horse, the subject an intelligent and previously healthy lad. The coincidence of carcinoma and sarcoma is extremely rare, but he has occasionally encountered carcinomata with sarcomatous stroma. They mostly occur in the ovaries, but he found one once in the esophagus, and once in the gall bladder, or pharynx, and they have been noted in the thyroids of animals. There are not more than 20 on record, and they usually affected young subjects, and were peculiarly malignant. In regard to pluricentric carcinomata, he states that he has seen a number, and notes that the disposition to plural carcinomata is especially marked in the paired organs. He mentions the peculiarity of diffuse carcinoma, involving an entire organ, to retain the function of the normal organ cells, as, for instance, no diabetes occurs in case of diffuse carcinoma of the pancreas, and no compensatory hypertrophy of the sound kidney is observed when its mate is affected with an infiltrating cancer. Superficial carcinoma is frequently multiple, especially the forms which are preceded by some inflammatory cutaneous affection. The coincidence of independent cancers has been observed in only a few instances in his experience. In one case a cancer in the stomach was accompanied by a cancroid on the right foot. In another, a carcinoma developing from an ulcer in the stomach coincided with carcinoma in both ovaries. In another, a carcinoma of the stomach was accompanied by a branchiogenic carcinoma in the neck; another presented a scirrhus of the stomach with an adenocarcinoma in the rectum; and still another, a cancroid in the esophagus with an adenocarcinoma in the stomach. These are all he has found in 1,000 cases of carcinoma since 1895. He has collected 22 examples from the literature in which carcinoma occurred simultaneously at neighboring points or at different parts of the alimentary canal or in parts with no connection between them, the only points in common in the latter group being that both cancers were carcinomata and on the same subject. He has never known of a case in which there were more than two cancers. In conclusion he remarks that the causes of cancer may be as manifold as there are different kinds of cancer. He thinks that the curable cancroids and the peculiarly malignant pluricentral carcinomata may prove to be quite separate entities. The possibility of a parasitic origin seems most probable for certain forms of sarcoma, especially those which develop regularly in multiple eruptions. He regards a parasitic origin as inconceivable for certain kinds of carcinoma and sarcoma, but for other kinds it is possible, but not established to date.

120. **Cancer Statistics.**—Wolff's investigations have revealed a number of cancer nests *in his part of Germany*, with a population of 11,703, showing 159 cancers in nine years. The stomach was affected in 86, the uterus in 25, and 98 of the subjects were women. In several instances three members of one family were affected. He calls attention to the predominance of cancers in organs with an opening to the exterior, like the stomach and uterus. He also suggests that exposure to the light and air seems to reduce the malignancy of cancer. Cutaneous neoplasms are more benign and exhibit a slower growth than those developing in the enclosed cavities in the body. In order to obtain more concerted action in cancer research he pleads for compulsory notification of cancer.

121. **Etiology of Cancer.**—Scherk *suggests the possibility* that the cause of cancer may lie in some disturbance in the anorganic balance in the vital processes in the cell. An altered proportion of mineral matters in the blood and organic juices may prepare the soil for bacteria or protozoa with cancer as the result.

122. **Improved Tuberculosis Antitoxin—*Hemoantitoxin*.**—Maragliano now produces a 20 per cent. solution of his tuberculosis antitoxin in an aromatic and alcoholic vehicle, containing likewise 5 per cent. of hemoglobin and 10 per cent. glycerin. A tablespoonful is administered before meals four times a day, and patients take it with relish. Figari relates that this antitoxin treatment by the mouth has scored in the clinic as fine results as those obtained in experimental research with the antitoxin by the mouth. He gives the details of 18 cases and mentions particularly the marked increase in the agglutinating power and the antitoxic and antibacillary properties acquired by the serum.

124. **Phono-Myoclonus.**—Bernabei applies this term to a continuous rumbling noise heard in the muscles in certain subjects when the ear is applied to any part of the body. The sound is loudest over the front of the chest, legs and buttocks, faintest over the abdomen, extremities, head and neck. The sound is audible whether the muscles are contracting or at apparent rest. Four pronounced cases in which it occurred typically are described by Sicuriani, who attributes the sound to incessant, rapid contraction of the muscle fibrils. All the subjects were neuropaths, and these sounds may aid in the diagnosis in the incipient stages of nervous disease.

125. **Danger of Protracted Organ Treatment.**—Ghedini submitted 25 animals to organ therapy, continued for two or three months. Each of the animals became weak and emaciated. He, therefore, warns that while the benefits of organ treatment have been established beyond question for certain cases, its continuous application is liable to prove injurious.

126. **Brain Organ Therapy.**—Fatal doses of strychnin were administered to animals, and while the controls all died those protected with cephalopin were saved. This is the oil extracted from brain substance, and it displays the action of an efficient organ extract. Twelve cases of epilepsy were apparently much benefited by injection of a few c.c. on alternate days. One patient has had no recurrence of her daily seizures since she began taking 2 c.c. of the cephalopin on alternate days, a month ago. It has also proved effective in other nervous affections.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE USE OF ETHYL CHLORID AS A GENERAL ANESTHETIC IN GYNECOLOGY.

E. E. MONTGOMERY, M.D.,
AND
P. BROOKE BLAND, M.D.
PHILADELPHIA.

DISCUSSION OF ANESTHETICS IN PRESENT USE.

The suggestion of a new agent for the purpose of securing general anesthesia will possibly seem unnecessary at this time, inasmuch as the agents now employed fill nearly all the indications required in anesthetic work. When we come, however, to analyze the action of these drugs, we find each of them has disadvantages which make us long for something by which these particular annoyances can be obviated. The length of time required to secure narcosis and to eliminate the drug, aside from the actual danger of the agents, make ether and chloroform unsatisfactory agents to secure anesthesia for an examination or for a short operation. The frequently prolonged nausea and vomiting associated with or following the administration of these agents for even a short time causes the patient to hesitate about undergoing the subsequent operation when they have been employed for merely diagnostic purposes. Perhaps in no department of medicine is the term anesthesia more repugnant than to the gynecologic patient; for in many instances the condition for which the patient consults the gynecologist has been induced by parturient trauma or infection, and during this time she has been anesthetized by one of our older agents, and, therefore, has learned of their annoying after-effects. Hence, if we can assure our patient that we can administer an agent free from these annoyances, the term will not have the same terrifying influence. The greater freedom from muscular action frequently renders an examination under anesthesia necessary in order to secure an accurate diagnosis on which subsequent therapeutic or surgical measures are to be based. Many will undoubtedly assert that nitrous oxid or the ethyl bromid would meet every indication for such diagnostic purposes, but they are not without disadvantage. Both act quickly and are evanescent in their effects, and the latter drug is likely to produce severe nausea. The former requires a special apparatus for its administration which is rather cumbersome to transport, and its administrator must exercise care to maintain its effects sufficiently long to permit of a prolonged examination or the performance of an operative procedure. The ethyl bromid is free from the above objections, but leaves an offensive garlicky odor on the breath which persists for two or three days.

The agent under consideration in this paper is free from these objections; indeed, so satisfactory is its action as to cause us to wonder that its salutary effects should have been so long overlooked. One probable explanation for this has been its excessive volatileness, which rendered it rather difficult to utilize and the associated expense which still renders its use unlikely in a general clinic.

CHEMISTRY OF ETHYL CHLORID.

Chemically, ethyl chlorid is one of the haloid substitution products derived from ethyl alcohol, and it is formed by the halogen element, chlorin, replacing the hydroxyl group in the alcohol. Various methods are employed in the preparation of this agent, but those most frequently used are as follows: First, by passing gaseous hydrochloric acid into a boiling solution of zinc chlorid in twice its weight of alcohol ($C_2H_5OH+HCl = C_2H_5Cl+HOH$); second, by the action of perchlorid of phosphorus on alcohol ($C_2H_5OH+PCl_3Cl_2=HCl+PCl_3OC_2H_5Cl$); third, by the action of chlorin on the hydrate of ethyl. Physically, ethyl chlorid is a clear, colorless liquid of rather pleasant odor, with an aroma somewhat similar to chloroform. It evaporates very rapidly at ordinary room temperature, and, therefore, must be kept in hermetically sealed vehicles. The specific gravity of this substance is 0.92. Its boiling point is 12.5 C. It is a highly combustible agent, and in burning emits a yellowish-green flame.

PHYSIOLOGIC ACTION.

[illegible] ction of ethyl chlorid still remains [illegible] question, though the general teaching, and that almost generally accepted, is that the influence of the agent on the circulation is at first to increase the frequency of the pulse-beats. After anesthesia is complete, however, the pulse will invariably regain its normal calmness. This primary disturbance of the circulation is undoubtedly due to nervous excitement and not to any direct influence of the drug, for, as is well known, this primary acceleration of the circulation is always found to precede the initial administration of any anesthetic. The arterial tension is, as a rule, decreased. Wood and Cerna, from their experiments with this agent on animals, found that it lowered arterial pressure during deep narcosis, and that as soon as the anesthetic was withdrawn, it regained its normal condition. Koenig, from his experiments on animals, has reached practically the same conclusions. Moreover, he found that the decrease in arterial tension was of centric origin. due to the influence of the agent on the pneumogastrics, since it disappeared after the vagi were cut.

Following the section of these nerves the arterial pressure increased and remained thus until the completion of his experiment. This observer further discovered that the pneumogastrics did not react to irritation when anesthesia was complete. Malherbe and Roubinovich carried out some experiments with Potain's sphygmomanometer in order to determine the exact influence of ethyl chlorid on the arterial pressure in man. The conclusions they reached are, in the main, in accord with those epitomized by the other investigators mentioned. Of the 24 cases examined by Malherbe and Roubinovich, arterial tension was decreased in 22, and the frequency of the pulse-beats followed equally the modifications in the degree of arterial pressure; during deep sleep diminishing and increasing and attaining finally the normal number as consciousness was restored. McCardie, from his large personal experience with this agent, also claims that the arterial tension is, as a rule, lower during the administration of ethyl chlorid, and that during deep narcosis the pulse becomes slower than normal, but usually maintains its regularity. Royer carried out certain experiments with this agent in his service at the Jefferson Medical College Hospital, and he found that its influence on the circulation was in accord with the observations of the other men mentioned. From our own personal experiments with this agent we found that in patients with a normal circulatory apparatus there was usually a slight decrease in arterial tension. There was no decided disturbance in the pulse-beat. At the beginning of the administration, however, there was a certain increase in the frequency of the pulsations, but this, of course, was due to the psychic disturbance of the patient, and not from any direct action of the drug. The respirations were generally stimulated both in frequency and depth, and from the perusal of the literature we find that this was observed by all of the investigators mentioned in this paper. A point of great importance, and one which we desire to set forth with emphasis, is that very little irritation results from the administration of ethyl chlorid on the respiratory mucous membrane. Furthermore, the distressing and often embarrassing condition of excessive secretion was scarcely ever observed from its administration. Malherbe and Roubinovich discovered in the urine of some of their patients which was normal before the anesthetic was given, the presence of albumin and bile pigments after the restoration of consciousness, but these substances disappeared in a few days. They conclude, therefore, that the kidneys and liver participate in the intoxication induced by ethyl chlorid.

SAFETY.

Regarding the safety of ethyl chlorid as a general anesthetic, from our experience we confidently believe that it is one of the safest now at the disposal of the practicing physician. McCardie asserts that it is the safest of all anesthetics except nitrous oxid, and that the death rate might be placed at one in many hundred thousand. Cumston ventures the statement that on account of the facility with which it is given and its harmlessness, an experienced assistant is not required. This assertion, however, does not seem to us justifiable. Cumston further asserts that chlorid of ethyl may be given to subjects at any age, and particularly at the two extremes of life at a time, he says, when the organism does not as yet present, or, on the other hand, has lost that vitality which is requisite to support the shock of our older anesthetics. Despite the harmless qualities of the drug, we believe that its administration or the administration of any anesthetic, should be trusted only to one skilled in the employment of such agents and trained to recognize their dangers. Seitz of Konstanz reports 16,000 cases of ethyl chlorid narcosis collected throughout the world. Among these there was but one death, and that in a very unfavorable subject. Ware has collected 11,207 cases of ethyl chlorid narcosis, and in this number one death is recorded. This fatality also occurred in a patient who exhibited many physical signs contradictory to the use of a general anesthetic. Soullier of Lyons records 8,417 cases of ethyl chlorid narcosis, and in all this number there were no symptoms induced that would condemn the employment of this agent. Lotheissen, on the other hand, asserts that statistics indicate that chlorid of ethyl stands, as regards its mortality, next to chloroform. This author asserts that death from chloroform anesthesia occurs once in 2,075 times, and from ethyl chlorid once in 2,550 times. The unfortunate result recorded in Lotheissen's series of cases occurred in a patient who manifested evidence sufficient to contraindicate the employment of any general anesthetic.

From a review of statistics and our own experience, we believe that the figures mentioned by Lotheissen relative to the chlorid of ethyl are far too high, and that his convictions regarding its safety have undoubtedly been fostered by the serious results obtained in one of his patients. The wide diversity of opinion regarding the safety of this remedy as a general anesthetic is due, we believe, to its comparative newness. In our judgment it is decidedly safer than chloroform and possibly safer than ether, and undoubtedly safer than its sister anesthetic, bromid of ethyl. This statement, too, we believe future experience will prove. Moreover, we have never observed a symptom from its use that rendered us apprehensive. Indeed, the assertion of Weissner would seem to indicate that the drug is really safer than ether. He states that in Prof. von Hacker's clinic in Innsbruck, ethyl chlorid is used whenever it does not seem safe to use ether or chloroform, as in high degrees of circulatory interruption, fatty degeneration of the heart, disease of the respiratory organs, persons enfeebled by great loss of blood, and those suffering from nervous shock. It is universally taught and accepted that the employment of any of our older anesthetics, such as ether or chloroform in patients with any of the conditions mentioned above, should be used, if at all, with anticipating caution.

ADMINISTRATION.

Ethyl chlorid was probably first used as a general anesthetic by Heyfelder, in 1848. In 1880 it was tried on animals by a committee of the British Medical Association and its use condemned, and for a time its use as a general anesthetic was abandoned. In 1895-96 Carlson and Thiesing again took it up and its use became more general, particularly in the practice of dentistry. Soullier of Lyons, in 1895, carried out clinical experiments with this agent in the hospitals at Lyons. He records 8,417 narcoses with ethyl chlorid without any direful results.

The first scientific work, however, and the first systematic employment of ethyl chlorid were probably done in 1897-98, by Ludwig and Lotheissen in Prof. von Hacker's clinic at the University of Innsbruck. Weissner later became chief of von Hacker's clinic, and carried on observations in 400 cases of ethyl chlorid narcosis. McCardie, in 1902-03, studied the value of the drug in 620 general narcoses, and he is enthusiastic in his praise of the agent, claiming that it contains all the requisites of a perfect anesthetic, and these we find are set forth by Tuttle as: 1, Safety to the patient; 2, insensibility to pain; 3, complete relaxation; 4, easy and rapid production of effect; 5, freedom from dangers and disagreeable after-effects; and, 6, simplicity of administration. Tuttle believes, too, that these facilities are nearly all inherent in ethyl chlorid.

Ethyl chlorid can be administered for the purpose of inducing general anesthesia by simply spraying it on a gauze compress, though perhaps the employment of one of the specially devised inhalers would be advantageous. One of the best inhalers now in use is the Ormsby ether inhaler devised by Hewitt. This instrument contains a movable air chamber which can be heated in hot water, and, therefore, prevent freezing and thus economize the use of the anesthetic.

Cumston recommends the inhaler devised by Tiemann & Company of New York, and in his hands it has proved very satisfactory, besides it is inexpensive. This inhaler is composed of an oval rubber cone containing a fenestrum in its roof about three cm. in diameter. Into this hole or opening, a tube five cm. in length is secured, through which the ethyl chlorid is sprayed into the cone. To prevent the anesthetic coming in contact with the patient's face several layers of sterile gauze are previously secured over the end of the tube. The same object is accomplished by inserting loosely a small plug of cotton in the lower end of the tube, with a single piece of gauze over the opening. We have employed this inhaler in our practice also, and it always gave us good results. In our experience a cone made of ordinary cardboard covered with gauze, with its base so constructed as to fit snugly over the face of the patient, has proved of good service in our hands. Several layers of gauze are secured over the opening on to which the anesthetic is to be sprayed. A rapid evaporation or escape of the anesthetic is prevented or minimized by placing a gauze pad over this. In administering ethyl chlorid for the purpose of securing general narcosis, the patient should be prepared as is done for the administration of any general anesthetic. The cone is applied tightly over the patient's face in order to prevent excessive intake of air. The patient is then instructed to breathe naturally. The agent is sprayed on to the cone more or less constantly from a tube with an opening sufficiently large to allow the rapid escape of the agent on to the cone. Should this not occur and if anesthesia is not promptly effected, two tubes should be used.

The time required for complete anesthesia is usually from one-half to two minutes, but with some persons a longer time is sometimes necessary. We have never failed to secure operative anesthesia, though in a certain number of our cases relaxation was more marked than in others. Most observers assert that complete muscular relaxation is never obtained, and this statement we believe in the main correct, though in our series of cases we noted in a few instances narcosis equivalent to complete relaxation. Lotheissen asserts that in cases of incomplete relaxation, the previous hypodermic administration of heroin would readily overcome the condition. It is asserted that excitement sometimes results from the administration of ethyl chlorid, and this condition McCardie says is due to the too free admission of air, though, at the same time, a certain amount of air must be allowed in all cases.

In our series of cases defensive disturbances were rarely noted. Thus far the teaching has been that ethyl chlorid finds its true service in the domain of minor surgery, or in that class of cases where prolonged anesthesia is not required, and many observers claim that it is of decided advantage preliminary to the administration of ether. A few men have used the drug for various major operations and report having had patients under its influence for many minutes. We ourselves have employed ethyl chlorid for almost every condition indicating the use of a general anesthetic. We have used it preliminary to the administration of ether, and heartily concur with the opinion of many men that the agent rapidly overcomes the excitation that results from the first stage of ether narcosis. Further, it undoubtedly decreases the amount of ether required, and, therefore, to a certain extent, combats the post-etherization nausea and vomiting. We have had patients under the influence of the anesthetic as long as fifty-four minutes, and under its influence have performed hysterectomy and the various combined operations on the pelvic floor and intrapelvic viscera.

USE IN GYNECOLOGY.

In gynecologic work ethyl chlorid will be especially employed for administration to allay the pain and relieve muscular contraction in abdominal pelvic examinations. Its employment will frequently permit of an accurate diagnosis in what would otherwise be an obscure case. The short time required for anesthesia, the rapidity with which the patient will recover from its effects, and the decreased tendency to nausea and vomiting, will allow its employment in office practice, with the assurance that the patient can return home without the need of prolonged attention.

The same indications will lead to its employment in all operations of minor character where prolonged anesthesia will not be required. In enfeebled patients requiring vaginal incision for pelvic drainage, it is an ideal agent, for its administration need not be begun until everything is prepared for the incision, so that the patient will be under its influence only a few minutes.

Probably its most effective employment will be as a preliminary to the administration of ether or chloroform, by which the distress and sensation of asphyxia produced by the latter agents will be avoided. A nervous woman may be brought quickly under the influence of the ethyl chlorid, and the ether or chloroform follow without the patient experiencing any of the ordinary discomfort of an anesthetic, and consequently, without a struggle. Her convalescence from the effects of the anesthetic is more rapid because she has not undergone so thorough a saturation with it.

DISADVANTAGES.

The principal disadvantages of the agent as a general anesthetic are:

1. The patient passes under and out of its influence so quickly that the administrator must be unusually expert to avoid, on the one hand, profound anesthesia, and on the other, the emergence from its effects at an important stage of the operative procedure.

2. The expense of the drug excludes its use in a general clinic, but the increased employment of this agent which must necessarily follow the general recognition of its advantages, will doubtless result in a reduction of its cost.

The Gauge of Sanitation.—The death rate of infants and young children—those under five years of age—is the true test of the sanitary conditions and of the sanitary administration of a community.—*Texas Medical News.*

THE ETIOLOGY OF TABES DORSALIS.

ARTHUR CONKLIN BRUSH, M.D.
Neurologist to the Kings County, Brooklyn Eye and Ear, and Williamsburg Hospitals, St. Giles Home, and Brooklyn and East Brooklyn Dispensary.
BROOKLYN.

Tabes dorsalis was one of the first of the diseases of the spinal cord to be recognized, and is one of the most frequent types of sclerosis which occurs in the cord; yet after more than half a century of study, there still exists a wide difference of opinion, both as to its etiology and pathology.

All our real knowledge as to its pathology may be summed up as follows: That it is a degeneration of the posterior columns of the spinal cord, or of the peripheral spinal sensory nerves, or both; and that this process involves primarily the posterior spinal ganglia or analogous neurons, and later involves the cord and peripheral nerves. But how these changes are caused, pathology has as yet offered us no explanation, and we must still rely for an explanation on the facts furnished by clinical observation.

Tabes is a disease most common in young and middle life, but its usual long and slow development often causes it to remain unrecognized for years, and thus the real cause may escape detection and the disease be assigned to some intervening factor. In a recent paper by Bramwell, who has analyzed 155 cases, the numbers, according to the age of onset, were, in the third decade, 79; fourth, 77; fifth, 35; sixth, 18; and seventh, 2. In 565 cases collected by Bonar, Thomas, Riley and Bramwell, there were in the second decade, 12.9 per cent.; third, 43.9 per cent.; fourth, 31.4 per cent.; and fifth, 11.6 per cent. In Fulton's 55 reported cases, the numbers according to decades were, third, 5; fourth, 16; fifth, 19; sixth, 7; and seventh, 2. A record of 103 cases of my own arranged according to the age of invasion, shows for the second decade, 1; third, 3; fourth, 47; fifth, 35; sixth, 16; and seventh, 1.

These figures, then, support the contention stated and are also held by some authorities to indicate that, by occurring at a time of life when the resisting powers are beginning to be impaired while the activity is undiminished, it is a disease of lowered vitality. This latter contention is also supported by the fact that the disease is much more frequent in males and those who live in cities. In my own cases, only four lived in the country, and only six were women.

The majority of writers assign numerous causes as the producing factors for tabes, such as syphilis, injuries to the cord and peripheral nerves, overexertion, exposure to cold and wet, acute rheumatism, typhoid and typhus fevers, diphtheria, pneumonia, influenza, alcoholism, sexual excess, severe hemorrhages, prolonged labors, and Fulton states that a number of his cases suffered for months or years from chronic gastro-intestinal disorders before the development of the tabes. Besides those cases for which we can find a recognized cause, we not infrequently see cases for which we are unable to assign an etiology. The relative frequency of these assigned causes as shown by Bramwell's reported cases, was, syphilis, 72.3 per cent.; alcoholism, 6.4 per cent.; injuries and exposures, each, 3.8 per cent.; mental worry, overexertion, diphtheria and scarlet fever, each, 1.3 per cent. In Fulton's cases, the frequency was, syphilis, 42 per cent.; alcoholism, 22.1 per cent.; influenza, 20.3 per cent., and typhoid fever and injuries to the spine, each, 7.4 per cent. In my own cases, the assigned causes were, syphilis, 59.9 per cent.; alcoholism, 5.7 per cent.; secondary to multiple neuritis, 4.3 per cent.; injuries to the spine, 4.3 per cent.; injuries to the lower limbs, 2.9 per cent.; blows on the back, 4.3 per cent.; rheumatism, 1.4 per cent.; sexual excess, 1.4 per cent.; diphtheria, 4.3 per cent.; and unknown, 11.5 per cent.

It is evident, then, that tabes is a disease which may either follow a large number of different causes, or that these assigned causes are not the real exciting causes; and that the tabes existed before the occurrence of the assigned cause and was aggravated by it, or attention was first directed to the tabes by the intercurrent disease. This situation is further complicated by the fact that it is impossible, either in private or hospital practice, to obtain clinical histories on which to base an opinion which meets with the requirements of a reasonable certainty. The only solution of this problem at the present time appears to be to take up each assigned cause and study the method by which it might produce the disease.

Led by the high percentage assigned to syphilis, it seemed at one time as if the majority of the profession had adopted the theory that tabes was simply a sequela of syphilis; and in those cases in which the occurrence of syphilis could not be proved, it was to be accounted for either on the theory that the infection was so slight that the symptoms escaped recognition, or on the grounds of heredity. This theory is, however, combated on the following grounds: That syphilis is common among the Japanese and negroes, while tabes is rare; that the tabes does not usually appear until long after all the manifestations of the syphilis have disappeared. (In my own cases this period averaged eight years and the extremes varied from two to thirty-three years. In Bramwell's cases this period was more than ten years in 59.5 per cent.) That the number of syphilitics is large, while the number of them who develop tabes is extremely small. In Leyden's 108 tabetic cases, only 28 were proved to be syphilitic, a percentage not above non-tabetic cases; and Lewin found no tabes in 800 syphilitic females, and Glueb found no tabes in 3,000 consecutive cases of syphilis. Beside these arguments against a purely syphilitic origin of tabes, it is further shown that antisyphilitic treatment has no effect in tabes; that the lesion is as degenerative in the non-syphilitic cases as in the syphilitic; that the disease is not a syphilitic one in its pathologic sense, and that all the morbid changes found in tabes also occur in other non-syphilitic diseases. The conflict of opinions of writers is thus shown in their works as follows: "No syphilis, no tabes" (Ferrier); "tabes is a syphilitic process" (Weigert); "it can not be said that tabes never develops unless the patient has had syphilis" (Bailey); "that syphilis is not the only cause" (Gowers); "it is not a syphilitic process or a sequela of syphilis" (Peterson and Burr); "that syphilis is the most important cause, but distinctly not the only cause" (Bramwell); and "that less importance is now being given to syphilis and more attention to the rôle of other poisons" (Fulton).

It is undisputed, then, that syphilis is a cause of tabes, but the method by which it acts has not yet been explained. Syphilis is supposed to be a germ disease, but whether it is the direct action of the toxins on the neurons of the posterior columns, or some secondary change in the metabolism of the body which acts in a similar manner or simply a lowered vitality of these parts or defective blood supply from vascular disease, is not yet in evidence. That it is due to the direct action of any syphilitic toxin seems impossible when we take into consideration the long period which elapses between the disappearance of all the other manifestations of the infection and the earliest signs of the tabes. Its action, then, if it is a cause, is very different from any other member of its class. The second contention is not yet based on any evidence of the existence of such a body, nor do either of these explanations offer any reason why the posterior columns of the cord are thus involved. A more reasonable explanation can be found in the fact that the posterior columns of the cord are of all the parts of the central nervous system the most poorly supplied with blood, and its venous supply is such as to tend markedly to retard the return of the blood; and thus any cause which tends to diminish either the quantity, quality or pressure of the blood supply to the cord would show its most marked action on the nutrition of the posterior neurons. This seems to be the most logical explanation of the relationship of syphilis and tabes, from its tendency to cause arterial disease.

When we consider the relationship of trauma and tabes, we again find ourselves confronted with a wide difference of opinion among writers. Bailey states "that it is improbable that injury or shock stand in any direct causal relationship to the disease." Prince, "that there is no published case which meets with the requirements of certainty." Gowers, "that one of the causes which can sometimes be clearly traced is injury." Golebiewski, "that the exciting trauma in tabes may act centrally or peripherally. The central injuries are hemorrhage into the cord, concussion or contusion; and the peripheral injuries are sprains, fractures or dislocations of the spine and contusions of the lower extremities." Excluding, then, those cases in which attention was first directed to an already existing tabes by some injury, let us examine the methods by which trauma might cause the disease. It is an established fact that disease of the peripheral portion of the spinal neurons may at times ascend to the columns and gray matter of the cord; and thus disease of the sensory fibers which ascends to the posterior ganglia may, by causing disease in them, cause similar diseased conditions of their central branch and thus ascend to the posterior columns of the cord. It will be remembered that the majority of the fibers of the posterior tracts of the spinal cord are but the central neuro-axon of the posterior spinal ganglia and depend on them for their nutrition. In this way, then, it must be admitted that tabes might be produced. Besides this method, and more frequently, the cord or its membranes may be injured by fracture, dislocation, undue bending of the spine or blows on the back, producing concussion, contusion or hemorrhage into the cord. This may be directly the cause of both the gray matter or tracts of the cord, or a chronic meningitis may occur ending in thickening of the membrane, compression of the cord and peripheral nerves with secondary degenerative changes.

In support of the theory of this method of the production of tabes, the histories of the following cases are of interest:

Case 1.—Male, aged 43, seen in Kings County Hospital. Four years before admission he fell down a flight of stairs, injuring his right knee. Since that time he has had loss of power in the right leg and thigh, with severe pain and hyperesthesia. Eighteen months before admission he began to notice unsteadiness in walking, numbness of his feet, and attacks of diplopia. Examination showed atrophy of the right thigh and leg, with the classical signs of tabes.

Case 2.—Female, aged 53, seen in Kings County Hospital. Ten years before admission she fell and received a contused wound of the right knee. Since then she has suffered from severe pains in the right thigh and leg; one year before, they occurred on the left side, and she noticed at that time difficulty in walking. Examination showed a large scar on the right knee and a well-developed tabes.

Case 3.—Male, aged 43, seen in consultation with Dr. W. Kinne. Two years before he had received a severe blow on the back which rendered him paraplegic and anesthetic below the third ribs with both urinary and fecal incontinence. He gradually improved so that he was able to walk with a cane. Two days before he was seen, he developed severe lightning pains in his body and limbs. Examination showed a well-marked tabes.

Case 4.—Male, aged 53, seen with Dr. L. S. Pilcher. Two years before he had received a severe blow on the back. This was followed by severe pains radiating from the spine into the hips and thighs, numbness of the feet, and retention of urine. Examination showed a forward displacement of the last two dorsal and first lumbar vertebræ, with a well-marked tabes.

Case 5.—Male, aged 38, seen in Kings County Hospital. Five years before he was in a trolley collision and received a fracture of two ribs and a contusion over the lumbar spine. Since that time he has suffered from spinal pain and rigidity, and two years later he developed severe pains in the chest and abdomen, often associated with vomiting. Examination showed a marked thickening about the lumbar vertebræ, spasm of the lumbar spinal muscles, producing spinal rigidity, and a well-marked tabes.

Case 6.—Male, aged 75, seen in consultation with Dr. C. D. Kevin. Always in good health until fifteen years before, when a cellar grating fell on his back. Since then he has suffered from severe pains in his back, radiating into his hips and lower limbs; numbness of his feet, and increasing difficulty in walking. Examination showed a well-marked tabes.

Case 7.—Male, aged 33, seen in Kings County Hospital. Seven years before he fell from a ladder and received a contusion over the lumbar spine. One year after he began to notice difficulty in walking and girdle sensations. Examination showed a well-developed tabes.

In none of the cases were we able to obtain from the family history or the personal history, or from the physical examination of the patient, any evidence of syphilis or other producing causes.

Alcoholism has been, next to syphilis, the most frequent assigned cause for tabes in my own cases. All had been addicted to the excessive use of the drug for years, and showed the well-known physical changes produced by this agent. In all there was a history of a peripheral neuritis, lasting a year or more before the development of the tabes. Of this class the following history is typical:

Case 8.—Male, aged 30, seen in Kings County Hospital. He had drank to excess for years, and had been treated in the hospital six months before his present admission for multiple neuritis, and discharged as cured. Present condition had been of three weeks' duration. Examination showed a partial paraplegia, most marked in the extensors, with foot drop, absence of knee-jerks, anesthesia dolorosa of the feet and legs, delayed sensations, and pain on pressure over the nerve trunks. He recovered except for severe pains in his lower limbs, and at the end of three years presented the ordinary clinical picture of tabes.

The explanation of this alleged etiologic relationship of alcohol to tabes is assumed to be found in the well-known toxic effect of alcohol on the nervous system, and its also well-known power to produce vascular disease. Besides this, alcohol also appears to have a selective action on the co-ordinating structures, as is well shown, not only in acute intoxication, but also in those cases which bear the name of pseudo-tabes or alcoholic tabes.

The method by which exposure to cold and wet might act as a producing cause for tabes is no more clear than the method by which it acts to produce other diseased conditions. The only case of this kind which has come under my observation was one in which the exposure first produced a neuritis which seemed to secondarily involve the cord.

Case 9.—Male, aged 67, a pastry cook, seen in Kings County Hospital. He gave history of two previous attacks, each of which occurred after exposure when overheated. The first occurred nineteen years before, and involved both legs, and the second one occurred one year later and also involved the arms. The present attack was of nine months' duration. Examination showed a well-marked quadriplegia, with foot and wrist drop, diminished knee-jerks, anesthesia dolorosa of the extremities, tenderness over the nerve trunks, and edema of the feet. The condition slowly improved, but at the same time he developed lightning pains, attacks of diplopia, and occasional retention of urine. By the end of three years he presented the ordinary picture of tabes, of which he died, and which diagnosis was confirmed by an autopsy.

The remaining alleged etiologic factors may be divided into three groups: 1, Toxins formed in the body as the result of some contagious disease; 2, toxins formed as a result of perverted metabolism; and 3, those factors which act by lowering the general vitality.

The first two groups may be considered together, for in both we are dealing with the relationship of a toxin to the nervous system. If we admit syphilis and alcohol as causes for tabes, it appears that we are now dealing with similar poisons, and that there is no substantial grounds for denial that other similar poisons might not act in the same manner. All these substances are known to be able to produce degeneration of the peripheral neurons, which may secondarily involve the cord, and also degeneration of the arteries. This contention is further supported by a recently reported case of Herzog, in which a tabetic condition followed a myelitis secondary to gonorrhea; and if the observations of Fulton as to the preceding digestive disturbances are correct, it would account for some of the cases in which we are unable to assign an etiologic factor. The etiologic relationship of the factor of the third group, such as sexual excess, prolonged labors and excessive hemorrhages, can only be explained on the theory that any cause in which the vitality is sufficiently reduced to produce degeneration of the neurons would, from the anatomic facts already cited, first show themselves in the posterior columns of the cord. This explanation, however, does not account for the fact that while these causes are very common, tabes ascribed to these causes is exceedingly rare.

To sum up, then, it appears from our present knowledge of the etiology of tabes dorsalis, that the disease can be as clearly attributed to other causes as to syphilis.

The "Goryous" Fourth.—Is it not about time to ask what, if anything, has been done, or will be done, to prevent the destruction of another four and a half hundred children following the next glorious and gory Fourth? When the extent of last year's statistics became impressed on the public mind, one heard some talk of legislation to suppress the toy pistol, and it began to look as if some definite steps would be promptly taken in this urgently needed reform. What has been done?—*Cleveland Medical Journal.*

A STUDY OF THE ANATOMY, PATHOLOGY AND ETIOLOGY OF SCOLIOSIS,

ALSO PRESENTING THE SCOLIOTONE, AN APPARATUS FOR ELONGATING AND LESSENING THE ROTATION OF THE SPINE IN LATERAL CURVATURE.*

COMPTON RIELY, M.D.
BALTIMORE.

In search for more definite etiologic factors and further pathologic conditions in scoliosis, I have found it necessary to make a thorough analysis of the spine, the various motions which it allows, and the physiologic relation which it bears to the pelvis, ribs and various muscles acting directly or indirectly on it. I also wish to say something in regard to treatment.

A STUDY OF THE ANATOMY OF THE SPINE.

The spine is a flexible column which tapers in size from below upward. In the cervical region the bodies are broader from side to side and have a tendency to limit the lateral as compared with the anteroposterior motion. Their superior and inferior surfaces are concavo-convex, and, of course, favor the motions in flexion and extension, and to a less extent from side to side, but have a tendency to limit rotation.

The articular processes in this region are oblique, and tend to permit flexion and extension and to restrict rotation; indeed, rotation can not take place without lateral bending, the greater part of all motions of the head occurring at the occipito-atlantal and atlanto-axial articulations. All of the processes in this region, both transverse and spinous, are short, which, of course, lessens the amount of leverage for rotation.

In the dorsal region the lateral and anteroposterior diameters of the bodies are about equal, their superior and inferior surfaces are flat, and have a tendency to limit flexion and extension, but favor rotation. The bodies being heart-shaped, favor oblique bending, especially as the apices of the heart-shaped bodies are forward. The articular processes are vertical, with the superior articular facets directed backward and outward, while the inferior look forward and inward; and this has a tendency also to limit flexion and extension, but to favor rotation. The spinous processes, being long and oblique and overlapping each other, limit extension, and, as they are close to the center of motion, favor rotation. The transverse processes are longer and directed outward and backward in this region, which circumstances tend greatly to favor rotation and to limit flexion and extension.

In the lumbar region the bodies are very large, and their transverse are greater than their anteroposterior diameters; this limits lateral motion more than flexion and extension, and also limits rotation. Their upper and lower surfaces are broad and flat, restricting flexion, extension and rotation. Their articular processes are vertical, and so arranged that the superior articular processes of one vertebra clasp laterally the inferior processes of the vertebra above it, making flexion and extension easy and rotation difficult. The spinous and transverse processes here are shorter than those in the dorsal region and their leverage for rotation less.

To sum up the result of this analysis, we see that the osteology in the cervical region is most conducive to flexion and extension; in the dorsal region, to rotation and lateral oblique bending, and in the lumbar region, to flexion and extension.

---

* Read before the American Orthopedic Association.

Now, in the dorsal region, in addition to the favorable conditions already named for rotation and lateral oblique bending, we have a most powerful set of levers, the ribs, which, through ligamentous attachments to the bodies and transverse processes of the vertebræ to the extent of one to two inches, according to the individual's size, when pulled on asymmetrically, may cause rotation and lateral oblique bending of the spinal column.

Now, while there are movable articulations between the ribs and dorsal vertebræ, their motion is limited, and when that limit is reached, they begin to act on the spine as rotators and lateral oblique benders in one-sided muscular action.

The costal cartilages being elastic and articulating with the sternum, do not limit asymmetrical positions and distortions.

The time of complete ossification of the vertebræ is not reached until the twenty-fifth or thirtieth year. The cartilaginous plates on their upper and lower surfaces do not begin to ossify until the twenty-first year, so that a constant rotation and a lateral oblique bending could readily change their shape.

In the pelvis the Y-shaped cartilages between the components of the ossa innominata begin to ossify as late as the thirteenth or fourteenth year, but the ossification of the ossa innominata is not complete until the twenty-fifth year. The sacral vertebræ unite between the eighteenth and twenty-fifth years. The sacro-iliac joints and symphysis pubis allow more play in childhood than in adult life.

Thus it will be seen how easily the pelvis can be distorted in growing persons, if faulty attitudes and irregular ossification from ill health, trauma, etc., are brought to bear.

On examination of the spine with the ligaments intact, one can easily see that the vertebral bodies are held together on all sides by a layer of inelastic ligaments, consequently no stretching of the intervertebral discs is possible, although unequal compression at any point may readily take place when force is exerted other than through the weight-bearing center. This inelastic ligamentous layer is reinforced to form the anterior and posterior common ligaments.

The elastic intervertebral discs of concentric vertical layers (and of heart shape in the dorsal region) favor compression, lateral oblique bending and rotation. The ribs being long, thin and naturally twisted, can be readily distorted by a continued disturbance of the muscular equilibrium of the trunk.

Each of the muscles of the abdomen, including the external and internal oblique, transversalis and recti, has partial attachment at one end to three or more of the eight lower ribs or their cartilages and at the other end to the pelvis. The first three are partially attached to the crest of the ilium, and with the recti are also partially attached to the os pubis; especially are their muscular portions attached to the iliac crest.

The external oblique, being the largest muscle of this group, having the most extensive bony attachment, which is the farthest from the center of the body and considering the direction in which it pulls, seems to be the most powerful for rotating and bending the spine. I think it never acts entirely independently of the muscles of the same or of the opposite side. This muscle is the only one of this group that is attached to the ribs proper, all of the others being attached to the costal cartilages. (The seven lowest costal cartilages are much longer than those higher up, and thus are capable of being more greatly distorted.)

As to the muscles of the back, I think, from my study of scoliosis, that they have been unjustly accused in the etiology of lateral curvature. The first and second layers are to support and control the movements of the shoulders. The other layers, except the iliocostalis and quadratus lumborum, are too close to the spine to have any appreciable power as rotators or even lateral benders, and they seem to be principally for erection of the spine.

PATHOLOGY.

Beely says: "We may consider the bones of the bodies as atrophied on the concave side and hypertrophied on the convex, but at the same time we must not forget that the atrophy in the vertical diameter is accompanied by a hypertrophy in the horizontal, and vice versa." From his description this malformation looks as if it must have taken place before complete ossification of the bodies. To this Bradford adds adaptive shortening of the ligaments and fascia of the spine.

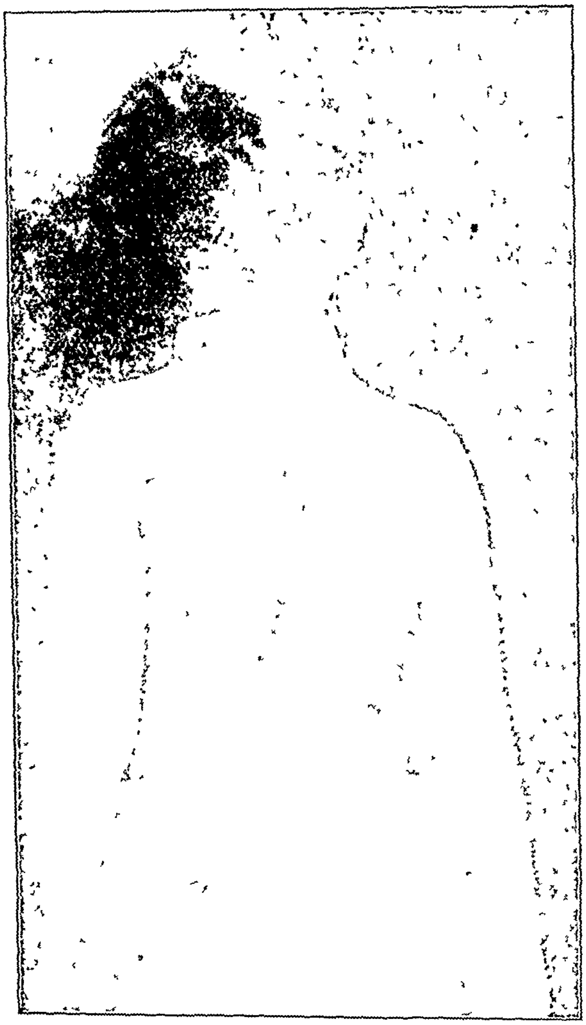

Fig 1—Patient showing scoliosis, rotation, lordosis and round shoulders

In addition to the wedge-shaped vertebral bodies and the contracted ligaments and fasciæ usually described by writers, I find that there is a distortion of the pelvis, the ribs and an inequality of the muscles of the abdomen. On the side of the concavity, the ribs are straighter at the posterior angles, more acutely curved anteriorly and are directed more obliquely downward than normal, while on the side of convexity there is the opposite condition, e. g., a more acute posterior angle, a straighter anterior extremity and a more horizontal direction of the ribs.

The ilium on the side of the concavity is tilted more forward, downward and outward than normal, while on the opposite side the ilium is more vertical and its crests more horizontal.

The abdominal muscles on the side of the concavity are longer and more tense, while on the convex side these muscles are shorter and flabby. The iliocostalis and the quadratus lumborum also seem shorter and more tense on the concave side of severe scoliosis, and the normal curves of the spine are increased.

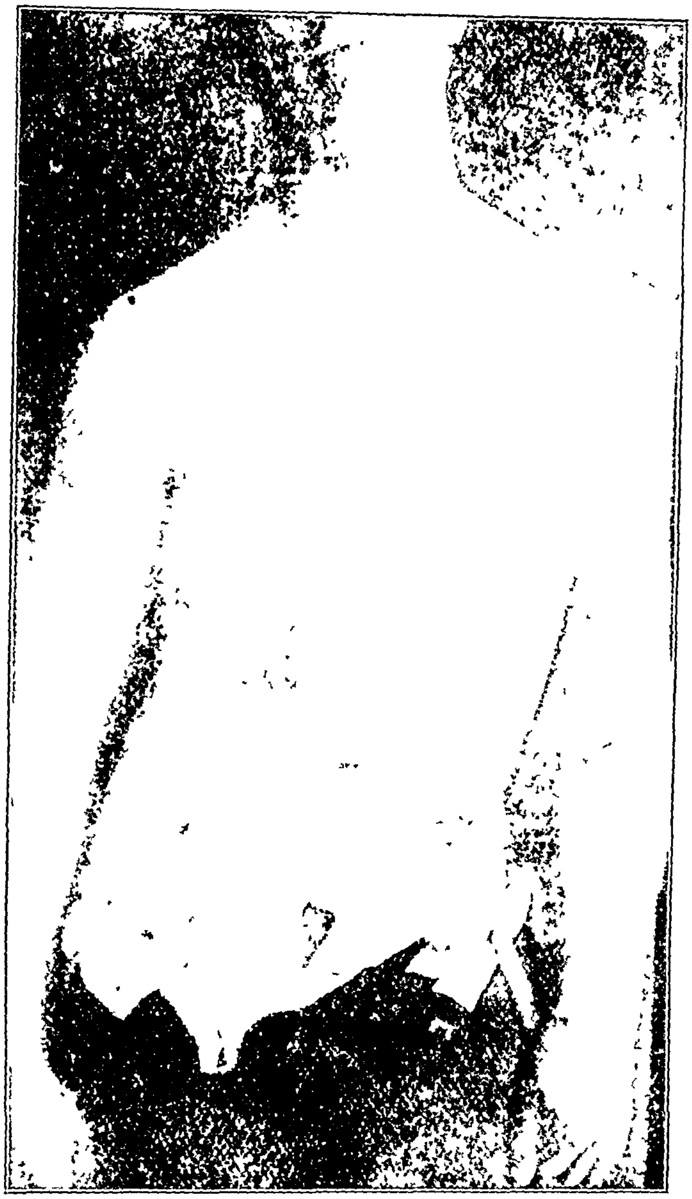

Fig. 2.—Left rotary lateral curvature in a normal individual produced chiefly by contraction of the right abdominal muscles.

Scudder has demonstrated that scoliotics are not up to the average in strength. This is easily explained when we analyze the existing conditions and see that the burden of supporting the spine is thrown mostly on one set of muscles, be they partly on one side or partly on the other. This weakened condition gives rise to the marked lordosis and stoop-shoulder (Fig. 1) accompanying these cases, the deformities being the result of the effort to maintain the equilibrium.

In the review of the literature on lateral curvature, I find a failure on the part of most writers to mention the distortion of the pelvis and ribs and the unequal length of the abdominal muscles on the two sides. McKenzie,[1] however, reports the case of a scoliotic girl, in which the right iliac crest was one inch higher than the left, and in which the left ilium was normally developed, while the right approached more nearly the vertical as in the male. These facts he attributed to the asymmetry in the development of the pelvis.

In examining the pelves of all the cases of scoliosis that have recently come under my observation, there seemed to be always an enlargement of one side. To prove this asymmetry of the bony pelvis, I made certain measurements. With the trunk bared, the shoes removed and the patient standing as nearly correctly as possible and without any undue exertion, measurements are taken as follows: 1. Between the anterior and posterior spinous processes of the ilium. 2. From the anterior superior spinous processes to the floor. 3. From the tip of the great trochanter to the floor. 4. From the anterior superior spinous processes to the internal malleoli. 5. Along Nélaton's line. 6. The shortest distance between crests of the ilia and the ribs on each side.

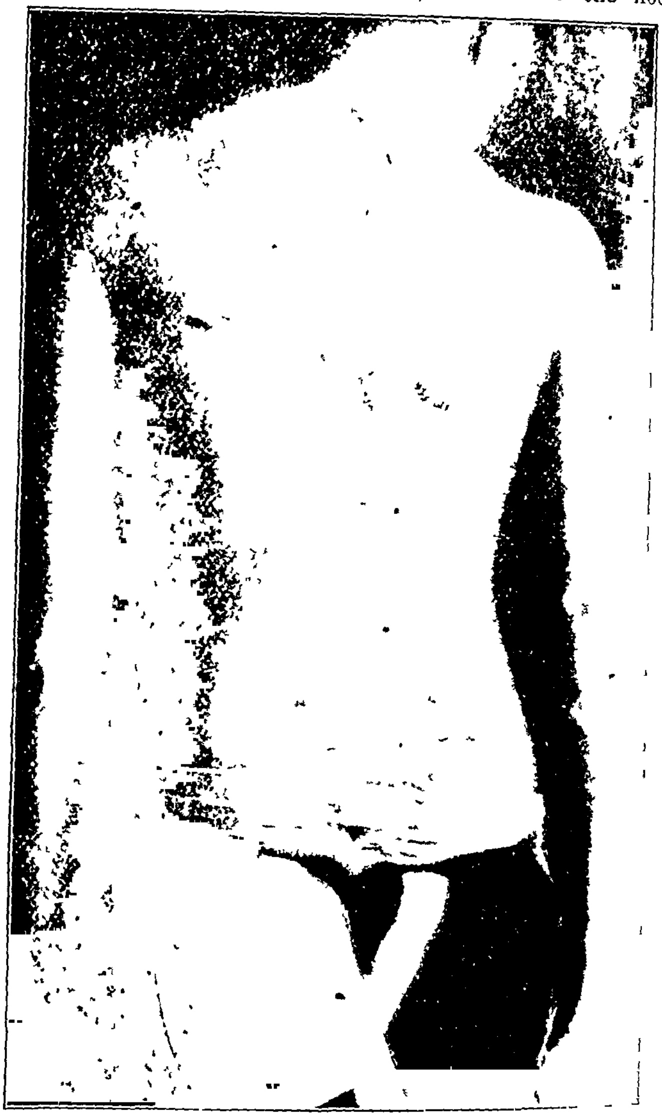

Fig. 3—Same individual, back view, showing increased obliquity of ribs on concave side of curve, also the narrowness of that side of the back

From these measurements I have found that the distance between the anterior and the posterior superior spines is about equal on the two sides; that the anterior superior spine was from one-half to three-quarters of an inch higher on the convex side when the legs are equal in length or when the leg is longer on the side of the convexity (as measured from the floor); that the distances from the anterior superior spines to the floor are nearer equal when the leg on the side of the concavity is longer; that it is impossible to get the correct length of the leg by measuring from the anterior superior spine to the internal malleoli, for they often measure the same between these points, when there is a considerable actual difference as measured from the great trochanter to the floor; that the trochanters are usually on Nélaton's line, and that the ribs are closer to the crest of the ilium on the side of the convexity.

ETIOLOGY.

Guerin claimed that scoliosis was produced by the active muscular contractions on the concave sides. Malgaigne taught that lax ligaments and weakened muscles on the convex side formed the predisposing causes. Bernard Roth thinks that the chief factors are weakness of the spinal muscles and long-continued standing or sitting in the relaxed or stooping positions. He has observed an inherited weakness of the muscles and ligaments, associated probably with excessive softening of the bone. He writes: "Anything which weakens the muscular system tends to produce lateral curvature."

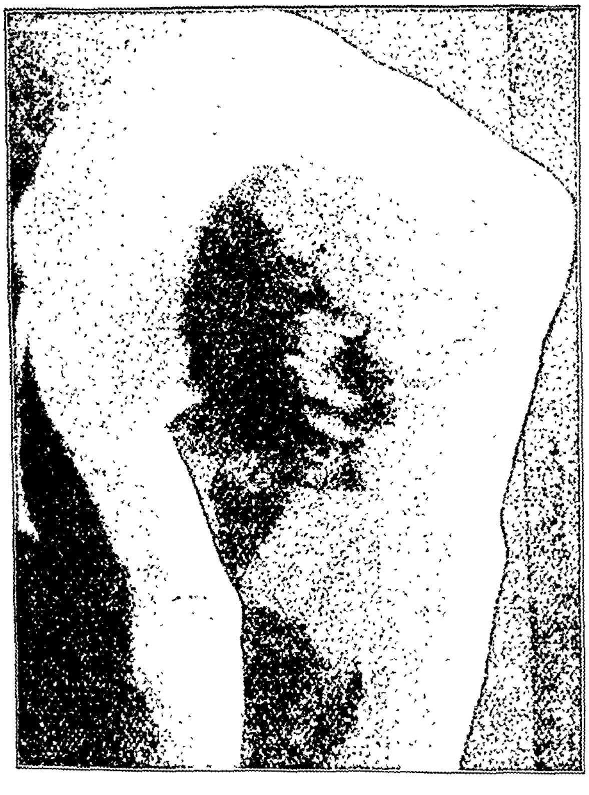

Fig. 4.—Same individual producing curvature and rotation in the forward-bending position by contraction of same muscles as in Figures 2 and 3.

Adams believed that, in the early stages of lateral curvature, spinal muscles on both sides are, as a general rule, decidedly passive, but that as the curvature advances the muscles on the convexity are called into increased action, and serve the purpose of limiting the extent and preventing the increase of the spinal curvature.

L. A. Sayre believed that rotary lateral curvature depends entirely on spinal muscular contraction. The spinal column, he says, is held in its normal upright position by the action of the muscles situated on either side of it, and which should exactly balance each other. If for any reason one set of muscles overcomes those on the opposite sides, the spine yields and a curve is produced with its concavity toward the side on which the stronger set of muscles is situated. Drs. Sayre and Adams differ in placing the strong muscles on opposite sides of the body. Schreiber believes that, in early stages of scoliosis, there are changes in the muscles, the muscular changes being due to long-continued stretching and disuse.

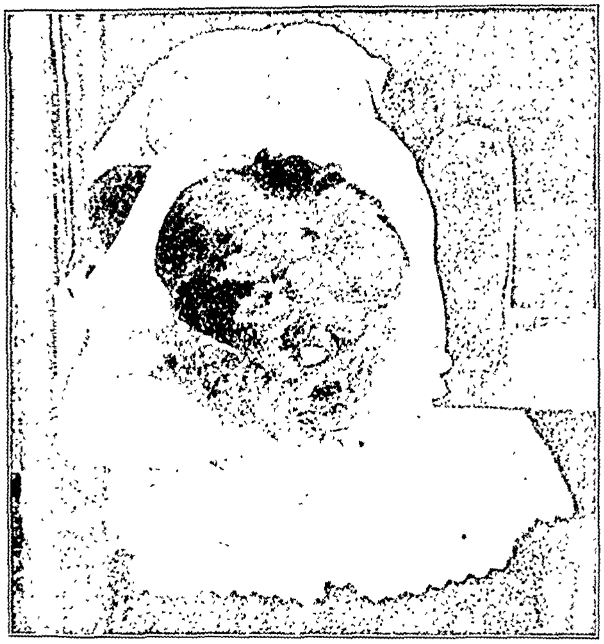

Fig. 5.—Resting on trestles; lordosis and round shoulder obliterated, back flattened, rotation and curve shown.

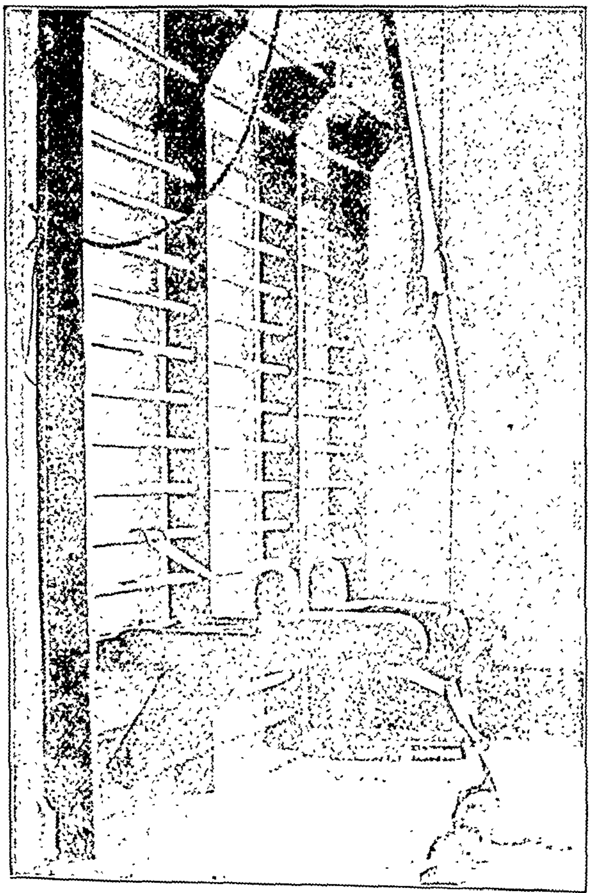

Fig. 6.—Scoliotone attached to rib stool.

Eulenberg holds that slight continuous muscular action is necessary for the maintenance of the upright position of the body; that this action must be equal on either side of the spine; that the most frequent cause of deviations of the spine is a disturbance of the power of the spinal muscle; that by frequently repeated passive torsion, necessary in assuming faulty positions, gradually the trunk muscles are weakened.

Lorenz sums up his opinion by the statement that anatomically, pathologically and clinically there is no foundation for a theory of a disturbed muscular antagonism, but that there is an element of general muscular weakness present in cases of lateral curvature, pure and simple, as has hitherto been assumed.

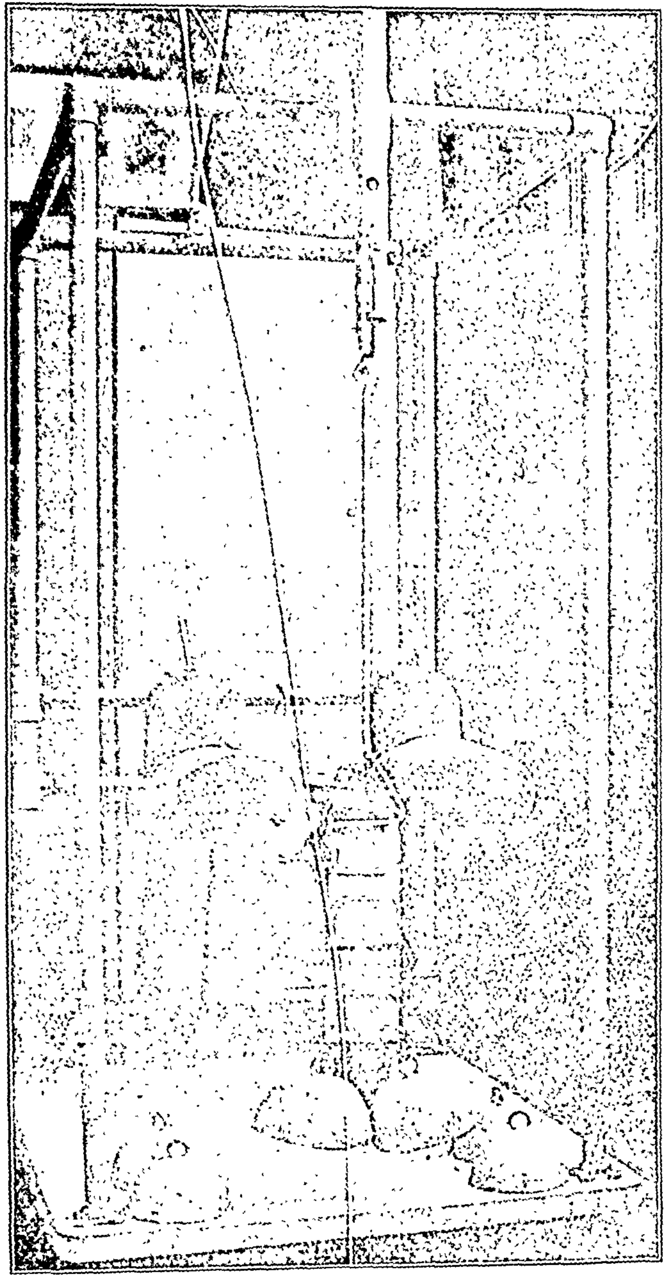

Fig. 7.—Scoliotone attached to gaspipe frame.

From my studies I am forced to hold the view that the distorted pelvis is the starting point of all cases (except those following paralysis, empyema and those accompanying Potts' disease); whether due to sitting or standing in faulty attitudes during the growing period before the bones have matured or while in a rachitic condition; unequal or irregular ossification; difference in the length of the legs caused by coxalgia, coxavara, congenital dislocation of the hip, acute inflammations, flat feet, etc.; that this is immediately followed by unequal action of the muscles of the abdomen (Fig. 2), so that those on the side, in which we find the anterior superior spine the lower, are put on the stretch, and hence act more forcibly in pulling the ribs downward, forward and straightening their angles (Fig. 3). The ribs in turn, through their long leverage on the spine, produce a dorsal concavity in it, and a rotation forward toward the same side.

On the opposite side, in which the anterior superior spine and the ribs are closer together, the abdominal muscles can not act efficiently and the ribs become more horizontal and curved at their angles (Fig. 4) and allow the bodies of vertebræ to rotate toward the convex side.

It is impossible at this time to present the full treatment antagonistic to these conditions, but I will mention a few of the most important points. Should there be an inequality in the length of the legs (as shown by the above measurements) they should be equalized, either by operation or mechanically, according to the cause. The patient should be imbued with the importance of assuming correct attitudes. Then we should establish a treatment by gymnastic exercises, jackets made over corrected casts and forcible machine correction that will tend to overcome the distorted pelvis, stretch and strengthen the weakened and shortened abdominal muscles, which further enables us to correct the distorted ribs, lordosis, stoop-shoulders, rotation and curves.

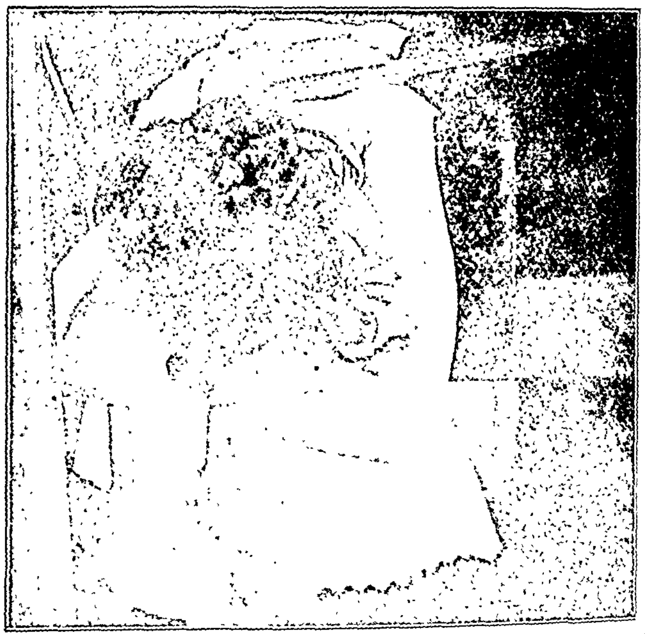

Fig. 8.—Rotation and curve corrected by application of weighted strap.

In conclusion, I wish to present the forcible correction machine, which I have called the scoliotone. This consists of two padded adjustable trestles, on which the upper thorax and pelvis are supported, with the legs at right angles to the body (Fig. 5). By these means we in a degree overcome the lordosis and round shoulders. On the end of each trestle is a padded upright, which causes counter-pressure against the axilla and the pelvis when the weights are applied. A strap armed with hooks to hold weights passes over the convexity, being made fast to the machine on the side of the concavity of the curve. This attachment of the strap to the machine is so accomplished by hooks that it may be adjusted by sliding along on a rod, so as to pull against the greatest angle of the deformity; and in addition, the rod to which it is attached may be lowered or raised, depending on whether we desire to act more on the rotation or curve.

This machine differs from Beely's in that it has fixed supports for the thorax and pelvis, while in his machine the patient rests on the feet and elbows.

This machine may be attached to the ordinary rib-stool (Fig. 6), or may have a quadrangular frame of gas-pipe to support it (Fig. 7). The weights are lifted by a lever, and the amount of weight varies according to the tolerance or resistance met in the individual cases. Patients can remain in this machine for a more prolonged period than in the majority of corrective appliances, and for the past eight months I have found it a most helpful aid in the treatment of this class of cases. It overcomes lordosis, straightens the spine antero-posteriorly from end to end, strengthens the abdominal muscles, and by means of the weighted strap tends to overcome the rotation and lateral deviation (Fig. 8).

A STUDY OF GONOCOCCUS METASTASIS; WITH REPORT OF A CASE.

JAMES McCOLGAN, M.D.
GRASS LAKE, MICH.
AND
JAMES M. COOPER, M.D.
ANN ARBOR, MICH.

Gonorrhea, as the term is ordinarily understood, is usually thought of as an affection of the urethra, or at most as a urethritis complicated by affection of the eye or joints, but the possibility of its being complicated by metastatic abscesses in various other parts of the body is not so generally kept in mind. It has only been within the last half century that practitioners as a whole have recognized the connection which exists between gonorrheal infection of the urethra and certain joint affections, and a thorough understanding of the nature of this connection has been possible for a much less time. It is generally admitted that Selle and Swediaur[1] were the first to recognize in the coincident urethritis the cause of what is now known as gonorrheal arthritis. Swediaur describes this complication of gonorrhea in his work entitled "Practical Observations on the More Obstinate Venereal Complaints," which appeared in London in 1784, reporting six or eight cases; and also in a treatise on syphilis, published in 1801.

According to John Elliottson,[2] Sir Astley Cooper, as early as 1806, gave notice of the fact that gonorrhea may be followed by painful disease of the joints. In his article on "Urethral Rheumatism and Ophthalmia," above referred to, Elliottson says: "I can remember the time when the most of the medical profession denied the occurrence of gonorrheal rheumatism, saying that a person with gonorrhea might, like any other, have rheumatism accidentally, or that a rheumatic patient might catch gonorrhea. My first knowledge of the occurrence of the disease was obtained from Sir Astley Cooper's lectures, which were delivered at St. Thomas Hospital in 1806-7 and 1807-8. How many years previously he had mentioned or seen it, I can not say."

In 1879, however, the discovery of the gonococcus by Neisser, and the observations made on it by Baumm, cleared up the question of the etiology of gonorrhea, and opened up new fields for investigation. Practitioners became divided into several schools as regards the question of gonorrheal rheumatism and gonorrheal metastasis in general. Some believed that the cause of the gonorrheal arthritis lies in the presence of the gonococcus itself in the affected joint, while others held that the arthritis, though due to the gonorrheal infection, was the result of the absorption of its toxins from the urethra. Still others asserted that the urethral lesion simply offered a port of entrance through which other pyogenic organisms could invade the body and so reach the joints or tendon sheaths. It was not long, however, before the gonococcus itself was discovered in the synovial fluid and membrane of affected joints by Petrone, Neisser, Long, Bordoni, Kamerer and Affreduzzi.

Attempts have been made at various times, notably by the earlier workers, to produce abscesses and other lesions by injections of pure cultures of the gonococcus, but with little or no success.

The writers have been able to find reported in the literature the following cases of suppurative lesions occurring during the course of gonorrhea, other than those in the urethra, in which attempts have been made to demonstrate the presence of the gonococcus as the exciting cause.

Smirnoff[3] found large numbers of gonococci in fluid obtained by puncturing an affected joint during an attack of gonorrhea. Sonnenburg[4] reported a case of caries of the hip occurring in the course of gonorrhea, in which gonococci were found on resection of the joint. Bockhart,[5] in a suppurating bubo and a periurethral abscess occurring during the course of a gonorrhea, found no gonococci, but the *Staphylococcus pyogenes aureus*. In another case he found gonococci in the pus of a kidney abscess which complicated a severe gonorrhea. Sahli[6] was able to demonstrate typical gonococci in pus corpuscles from a large abscess in the neighborhood of the knee joint.

Weichselbaum[7] found the *Streptococcus pyogenes* on the valvular vegetations in the heart of a 25-year-old man who had died from ulcerative endocarditis three weeks after the contraction of a severe gonorrhea. He also found some organisms on the valve flaps resembling in some particulars the gonococcus, although not grouped in the same way, and staining well with Gram's.

Haab[8] reports a case of a patient suffering from a severe general infection, with effusions in the knee and elbow joint and abscesses in the left axilla, and who had lost an eye from gonorrhea. In the abscess in the armpit there were found staphylococci but no gonococci.

Guyon and Janet[9] punctured the knee joint in three cases of gonorrheal arthritis, and in the seropurulent fluid were unable to find any micro-organisms either by the microscope or by various culture tests. They believed, therefore, that these cases were instances of the action of ptomains produced as a result of the growth of the gonococcus in the urethra.

In 1893, Lang and Paltauf[10] reported a case in which an abscess, associated with a teno-synovitis, occurred on the back of the hand, and in which the presence of the gonococcus was demonstrated both microscopically and by cultural methods.

Horwitz,[11] in 1893, reported a case similar to the preceding and to the one which is reported below, associated with a tendovaginitis. The gonococcus was obtained in pure culture on serum agar, and also demonstrated in cover slip preparations stained with methylene blue, being found both free and contained in the pus cells.

Bujivid,[12] in 1895, reported a case of abscess due to the presence of the gonococcus, unassociated with infection of any tendon sheath. The patient was suffering from a chronic gonorrhea, and two days after catheterization had a severe chill, after which abscesses developed in the right popliteal space, in front of the elbow, over the right external malleolus and on the inner side of the left leg. The author states that all of these had their origin in the muscles, and none in the cellular tissue or neighboring articulations. He therefore classes the gonococcus with the pus-producing organisms.

Young[13] reports five cases of subcutaneous abscesses in the course of gonorrhea, in all but one of which the gonococcus was found alone. In all of these the abscess was adjacent to the urethra or to some synovial membrane.

Deutschmann[14] found organisms which were characteristic gonococci with regard to form, size, grouping, staining reactions and cultural characteristics, in the synovial secretion of an affected knee of a child suffering from ophthalmia neonatorum.

The patient in the case studied by the writers is a woman of about 40 years of age, married, and a housewife by occupation. Her present trouble began July 25, 1903, as sharp shooting pains around the base of the right thumb and index finger, which after 24 hours became so severe that medical aid was summoned. The hand was found on examination to be slightly swollen, especially over the location of the pain. Her temperature was found to be 101 F. Any motion of the index finger was extremely painful, especially movements of the metacarpophalangeal joint. The patient's husband had been under treatment for gonorrhea during the previous month, and consequently the present trouble was suspected to be a complication of a gonorrhea which the patient had acquired from her husband; but close inquiry failed to elicit any history of such a condition. She was therefore placed on antirheumatic treatment, and the pain controlled by sedatives, but without beneficial result.

The swelling and redness became more pronounced, and August 2 an incision was made over the proximal phalanx of the index finger, both above and below, resulting in the evacuation of a small amount of purulent material. After this the temperature fell to normal, but in the course of a few days rose again, and the swelling extended to the palm and dorsum of the hand. August 16 free incisions were made into the diseased area under chloroform anesthesia, and a considerable amount of pus was evacuated. The pus cavities were curetted and washed out thoroughly with a hot carbolic solution. The subsequent treatment consisted of hot bichlorid irrigations and antiseptic dressings. Recovery was uninterrupted, but the involvement of the flexor tendon resulted in its shortening, which prevents the complete extension of the index finger. There was no ankylosis of any of the neighboring joints. This fact, together with the evident involvement of the flexor tendon, indicates that the condition was purely a tendovaginitis.

BACTERIOLOGIC INVESTIGATION.

The freely flowing pus, obtained at the second operation, was received on a sterilized platinum loop and transferred to liquefied gelatin and agar tubes (45 C.). The gelatin tubes were kept at room temperature, and the agar tubes in the incubator at 37 C., for some days, without, however, showing any growth. Unfortunately, tubes of serum agar were not at hand, and growth on this medium was not attempted. Thin spreads of pus obtained as above were made on cover glasses, dried in the air, and fixed lightly in the flame. A portion of these spreads were stained with Loeffler's methylene blue, the balance with a 1:10,000 solution of neutral red. On examination, these preparations showed the presence of groups of "biscuit-shaped" diplococci, although not in very large numbers—not more than one or two such groups to a field (1/12-inch oil immersion). Similar diplococci were also found within the cell bodies of the leucocytes, and in all respects as regards form, size, arrangement, staining reaction, and grouping were typical gonococci. They were readily decolorized by Gram's method.

Although the organism could not be cultivated on the media employed, the characteristic appearance of the flattened diplococci, the grouping, the presence of the organisms in the pus cells, the decolorization by Gram's stain, and, above all, the inability to grow on the ordinary media, on which the ordinary pus germs readily thrive—leaves no doubt that the organism in question was none other than the gonococcus of Neisser.

The fact that such metastatic abscesses, due to the gonococcus alone, can occur in various parts of the body, even in the absence of symptoms on the part of the urethra or other portions of the genito-urinary tract, being established, the importance of routine microscopic examinations of pus from such abscesses, especially those connected with tendon sheaths, is apparent. A patient such as the above becomes an especial danger, not only to herself, but to those with whom she is associated, unless the true condition is understood. It is readily seen that the liability of such a patient to contract a gonorrheal ophthalmia or to infect the eyes of others, is infinitely greater than when the disease is localized in the urethra. The transference of purulent matter to the eyes of such a patient or to those of her young children, from an abscess on her hand, is indeed more of a probability than a possibility, unless especial precautions are taken to prevent.

Aside from the danger to which the ignorance of such a condition subjects the patient and her associates, the clinical discovery of the gonococcus in such an abscess affords a clear indication as to subsequent treatment. It is probable that in all cases the organisms growing in such metastatic abscesses have migrated from the mucous membrane of the urethra, this locality being, par excellence, the most suited for their growth. It is also probable that here they will be found in greatest numbers, whether the patient presents symptoms of urethritis or not. Proper treatment directed to the urethral condition should, therefore, be employed in all cases. First, for the purpose of curing the primary condition; and, second, as a prophylactic measure against other possible metastatic complications, endocarditis or synovitis, and especially to forestall the more serious dangers to which every sufferer from a chronic gonorrhea is liable.

TREATMENT OF TYPHOID PERFORATIONS.

LOUIS FRANK, M.D.
Professor of Abdominal Surgery and Gynecology in Kentucky University, Medical Department; Surgeon to the City Hospital; Member of Surgical Staff of John N. Norton Memorial Infirmary.
LOUISVILLE, KY.

While the modern methods of treatment by the general practitioner have done much to reduce the percentage of deaths due to typhoid fever, the rôle played by the surgeon in lessening the death rate occupies a conspicuous place.

The tubbing and proper feeding do much to keep down temperature and maintain strength, but no medicinal agents nor the most careful management can overcome the great danger of intestinal perforation by ulceration. From a careful perusal of the literature and consultation of authorities we find that about 3 per cent. of all cases present this most dangerous complication, i. e., it is the cause of one-fourth to one-third of all deaths in typhoid fever.

---

[12] Centrabl. f. Bac. u. Parasit., Jena, 1895, xviii, 435.
[13] Jour. of Cut. and Gen. Urin. Dis., 1900, xviii, 241.
[14] V. Graefe's Arch. f. Ophthal., xxxvi, 1.

In 3,686 cases, Schultz found peritonitis from perforation in 1.2 per cent., Liebermeister in over 2,000 in 1.3 per cent., while Hölscher found it in 6 per cent. in 2,000 cases, and Murchison in 11.38 per cent. in 1,721 cases. Fitz shows the mortality to be 6.58 per cent. from perforation in 4,680 cases tabulated up to 1891. In more recent times, since the subject has been more thoroughly studied, we find that Armstrong reports 932 cases, with 3.66 per cent. perforations, and McCrea and Mitchell cite 8 cases occurring in 275 patients. This, in comparison with the present-day mortality, would mean a very large proportion of deaths in typhoid fever due to perforation, for under former methods of treatment these cases practically all died and to-day the death rate from this cause continues large.

In 1898, Keen reported a total of 83 cases of typhoid perforations operated on with 19.3 per cent. recoveries, to which a year later, he added 47 cases with 28 per cent. recoveries. This work was largely done in this country, due probably to the doubt as to the efficacy and advisability of operation existing in the minds of the European surgeons, as expressed by Eulenberg in his paper in 1891.

In Keen's monograph, which caused the profession to awaken to this subject, he says that the accident is a very rare one in children, but Elsberg, in a very recent communication, thinks it almost as frequent as in the adult. Basing the frequency of cases in children as seen by the surgeon, i. e., 48 cases in a total of 315, we must conclude that, though not occurring as often, it can not be considered as an infrequent complication in children. We would especially call attention to these figures, in view of the fact that typhoid fever is said to be not only much more seldom seen in children, but that it also runs a far milder and shorter course. It may be of interest to know that one of Chevalier's cases was in an infant of 11 months of age, and that this author, in a large experience with the young in the hospitals of Paris, believes it to be a source of great danger in them.

Recognizing these facts, we should then be constantly on the alert for the very first symptoms indicative of perforation. It may take place at almost any time, even during the first week of illness, though most often after the second week. This is contrary to the older teachings and also the opinions which are held by many practitioners, it being popularly thought that the end of the third and beginning of the fourth week of illness is the time when this danger may be expected. It is not always an easy matter to determine the date of the illness, even after careful inquiry, as many patients are ill for a variable time before a physician is consulted or before they take to bed. In some of the reported cases the signs of perforation were really the first warning the patients had that they were very ill and were also the occasion for consulting medical advice.

It is also a mistake to believe that after the fourth week this danger is passed, for as many cases have been reported as taking place in the tenth as in the first week. Of 193 cases of perforation, tabulated by Fitz, the time of occurrence was as follows:

First week 4, 2d week 32, 3d week 48, 4th week 42, 5th week 27, 6th week 21, 7th week 5, 8th week 3, 9th week 2, 10th week 4, 11th week 3, 12th week 1, 16th week 1.

SEAT OF PERFORATION.

In 85 to 90 per cent. of cases perforation takes place in the last twenty inches of the ileum, though it may occur in the colon, and several cases of appendiceal ulceration and perforation have been recorded. The sigmoid may be the seat of the opening or the jejunum, and in the table of Fitz above quoted, it occurred four times in a Meckel's diverticulum.

SYMPTOMS AND DIAGNOSIS.

No case of typhoid should be so mild as to cause us to lose sight of this dreaded accident. We believe that the symptoms are such that a diagnosis can be made correctly in the majority of cases, if one is on the lookout in the least. These symptoms are those due to the insult to the peritoneum, and are not dependent on the perforation *per se*. The classical signs are pain, rigidity, tenderness. With these we have thoracic instead of abdominal respiration, which means fixation of the diaphragm, inhibited peristalsis, absence of liver dullness, tympany, vomiting, increase in blood pressure as shown by the sphygmomanometer in all cases, leucocytosis, increased pulse rate followed by rising temperature and altered facial expression and shock. Let us very briefly analyze the symptoms:

Pain is not a necessary accompaniment of typhoid, and while it may be present during the course of the disease, it is not continuous or persistent, but is temporary. Nor is the onset sudden as a rule, unless as an indication of some severe and dangerous complication. Ordinarily it is relieved by an enema. On the contrary, the pain of perforation is sudden and may follow a stool or manipulation of the patient. It begins in the hypogastric, though more often in the right iliac region, and spreads thence gradually over the entire abdomen. Not infrequently a stool soon follows, giving some temporary, slight relief. The pain may increase and be continuous or may after a time cease entirely, which means that a general toxemia has supervened. Even in the smallest pin-hole openings this pain is present. Persistence of pain without the slightest evidence of shock, if accompanied by rigidity, is almost sure to mean perforation. Acute or sudden or continuous pain should always be a danger signal and cause the attendant to redouble his care and vigilance, making more frequent visits and getting into touch with a surgeon so as to be prepared for the emergency. It may denote, in the absence of perforation itself, an ulceration through to the serous coat of the bowel and the approach or early possibility of extension through all the coats. It is the peritoneal layer alone which possesses nerves of sensation, hence the pain at this stage. Ulceration, no matter how extensive so long as the peritoneal coat is uninvolved, causes no pain.

Rigidity is one of the most valuable signs of peritoneal damage we have. It is noticeable almost at the beginning and may be present even before the perforation. Just as pain may denote an impending perforation, so may rigidity be found before the damage has extended through the peritoneal coat of the bowel. Localized at first to the affected area, it soon spreads over the entire abdomen, indicating spread of infective material. Unlike pain, which may be well borne and not cause much complaint in certain stolid individuals or in those profoundly septic or which may grow less and even cease as toxemia advances, rigidity is constantly present. The patient can not voluntarily overcome it. Its presence in the diaphragmatic muscle causes the alteration in type of respiration from abdominal to costal.

Tenderness usually exists most markedly in the right iliac region, i. e., over the seat of perforation, and over the now most violently affected serosa. It soon becomes more or less general, but may be slight over the abdomen, except in the region above mentioned or the hypogastric region. Osler says the attendant must be constantly on the watch for the sudden occurrence of the above three symptoms.

Inhibited peristalsis is, according to Taylor, a very important symptom. Not infrequently we find, however, that the inhibition has been preceded by a very active peristalsis immediately following the perforation as indicated by the two or three copious evacuations, which at times follow the onset of the very earliest manifestation of pain. These stools may contain blood from the perforating ulcer. That inhibition follows we can readily understand, and as the infection progresses, it becomes complete, resulting in paresis, which, in my opinion, indicates absolute hopelessness of recovery in this as well as in other peritoneal involvements.

Tympany and absence of liver dullness with pain, are, to our mind, the only really indicative symptoms of the perforation *per se,* all other symptoms being those of the infection rapidly following the peritoneal insult. This symptom, however, is so rarely present early that it is difficult to see how one is to differentiate the symptoms of the perforation from those of the peritonitis, which latter are the ones on which we depend for a diagnosis. Escape of gas is apt to take place so gradually that it is hardly a symptom to wait for before making a diagnosis, notwithstanding the fact that its presence is almost pathognomonic. I have seen cases with little tympany even hours after the perforation had occurred.

Besides the above local symptoms referable to the abdomen or seat of lesion, we have other symptoms serving to corroborate the diagnosis. We should not lay too much stress on them, as the local symptoms are, without these, enough on which to place the strongest reliance and base a sufficiently strong presumption.

Vomiting may or may not be present; in fact, it is not a symptom in more than 7 to 10 per cent. of the cases reported.

Blood pressure, measured by the sphygmomanometer, according to the reports of Crile and the Johns Hopkins School, furnishes a most valuable means of diagnosis. The cases are, of course, too few as yet to say with absolute certainty what the exact value of a rapid rise in blood pressure as thus indicated is, but from my experience I am inclined to believe this instrument will or should come into as general use as the stethoscope.

Crile, in five cases at Lakeside, made a diagnosis by this means, all verified by autopsy or operation. In one case a second perforation was also indicated by a rapid rise in blood pressure. With subsidence of peritonitis the blood pressure fell rapidly to normal again.

Leucocytosis has been shown to be of value only in connection with the other symptoms. This is probably accounted for by the rapid outpouring of leucocytes into the peritoneal cavity as a result of the infection. As McCrea and Mitchell have shown, even with other symptoms it may be misleading, two of their cases with this evidence and other symptoms presenting no perforation at operation. Armstrong, with an experience of 34 operated cases, says it is not to be relied on. Elsberg says: "It can be used only with circumspection as a diagnostic symptom, while the absence of a leucocytosis does not exclude the possibility of a perforation."

Pulse and temperature, of all the signs of perforation, are the least valuable. The character of the pulse is a very valuable sign, but the rate is hardly to be depended on. Like temperature, it means very little in many instances, and both are so frequently misleading that no reliance can be placed in either as even fairly constant from a diagnostic standpoint.

Facial expression may not be altered, except to indicate pain. Not infrequently, however, the expression is pinched, anxious and indicative of a very grave change in the patient's condition. When there is much shock this is especially true, and we have the expression so graphically described by Warren in this condition, when, as Gross says, the "machinery of life has been rudely unhinged."

Shock may be very marked or absent or so slight as to pass unnoticed. When marked it is a symptom of value only as indicating a most desperate case. I wish here again to draw attention to shock as a symptom not of perforation *per se,* but rather of a rapid and profound poisoning. The text-books lay entirely too much stress on this symptom of perforation. In my own experience in the one case operated on it was never a symptom, and I have seen other cases in which it was entirely absent. Without bleeding, this symptom is one either of rapid sepsis, with consequent obstruction or of early impending death. Notwithstanding this, it is not an indication for delay in treatment.

Of all these symptoms, the most important are pain, tenderness and rigidity.

TREATMENT.

To obtain the best results, the operation should be done promptly within certainly the first twenty-four hours; better still, as soon as a probable diagnosis is made. Of the six recoveries reported by Armstrong, five were operated on within thirteen hours after the first symptom, and Cushing believes that with careful watching and early diagnosis, 50 per cent. to 60 per cent. should be saved. In other words, we should operate if possible before the peritonitis becomes too general and too virulent. As lives have been saved, however, even in very late cases, who can say when a patient is beyond hope of recovery? One life in 100 or even in 1,000 is worth saving.

Some will say that cases may get well without operation. True, but as Fitz says: "Since perforation may take place without any suggestive symptoms, and since suggestive, even so-called characteristic symptoms, may occur without any perforation having taken place, it must be admitted that recovery from such symptoms is no satisfactory evidence of recovery from perforation."

It is also true that sometimes we may make mistakes and find no perforation, but we must remember that a peritonitis may exist without perforation which may demand celiotomy to rescue the patient. Murphy has especially called attention to this and reported several cases. In these, while there is no perforation, the ulceration has extended through all the coats except the serosa, and we have the bacteria finding their way through this thin wall into the peritoneal cavity. The symptomatology may then be precisely the same as in perforation; in fact, exclusive of the hole in the bowel, the pathology and outcome are similar. Chevalier says: "Operate even when the diagnosis is not fully decided," which means, of course, to operate promptly. Do not wait for all the positive and confirmatory evidences of the trouble or the golden opportunity will have been lost. Nor should we be too greatly perturbed about shock when present, as it is in these cases no indication for delay. Some of the best results have been in patients operated on in shock.

As to the technic of the operation, I would only say, do not try to do too much. Do not lose time in useless tinkering and fussing. Do the work quickly—best through an incision in the right linea semilunaris—close the opening in the bowel, and be sure to amply drain the cavity. If the opening is not readily found, let it be and drain extensively. To prolong the operation needlessly is bad surgery. If the patient is a bad subject for a general anesthesia, use a local anesthetic.

Escher has recommended stitching the edges of the intestinal opening to the parietal incision, and Le Compte advises damming off the infected area, particularly when there are multiple openings near each other, with a gauze wall. An artificial anus presupposes only one perforation. The mattress Lembert suture is looked on as the best. Extensive flushing and leaving some of the normal saline solution in the belly, with of course drainage, is, I believe, the preferable way to overcome the peritonitis, although Finney and others continue to advise dry mopping of all infected areas.

In conclusion, I wish to read the following table of Elsberg and some additional cases I have found in the literature bringing the reported cases to date:

REPORTED CASES OF OPERATION TO APRIL, 1903.

	Adults.	Children.	Total.
Cases operated on	264	25	289
Recoveries	59 (22.4%)	16 (64%)	75 (25.9%)
Deaths	205	9	214 (74.1%)

ADDITIONAL CASES.

	Cases.	Recoveries.
Armstrong	8	5
Crile	4*	2
Chevalier and other Parisian surgeons	13	5
Frank	1	0
Harte	13	3
Méry	1	0
Total	40	15 37.5%

*One unoperated.

Of these last, 14 are reported as children with 5 recoveries, or 35 57 per cent.; 26 adults, 10 recoveries, or 38.46 per cent.

My own case was as follows:

A man, 32 years of age, in the third week of typhoid fever, living in the country, was seized with a sharp pain in the right iliac fossa, which disappeared after copious movement of the bowels. Two hours later his temperature became very slightly subnormal, and continued so or normal for twenty-four hours. When seen by me 60 hours later his temperature was slightly above 99 F., pulse between 86 and 90, though it rapidly rose to 112. There had been no vomiting, and distension of the abdomen had been present for only a short time after the sudden pain. The patient presented a good appearance, without pain or tenderness, and was not depressed. Tympany was present over the entire abdomen as far as the fifth intercostal space, with marked rigidity and absence of liver dullness. The pulse was hard and characteristic of peritonitis. Diagnosis of perforation was made, with prognosis of death, with or without operation. The patient asked that he be given the slight chance by operation. On opening the abdomen it was found filled with pus and fecal matter and the intestines distended above a point about eighteen inches above the perforation, below this point the intestine was flat. The perforation was closed with difficulty, the cavity washed out and five drains inserted. The patient was put to bed in fairly good condition, and next morning had a pulse of 130, no vomiting or pain. He died on the second day.

CONCLUSIONS.

From the foregoing we can make the following summary:

1. Perforations are to be expected in about 2.5 per cent. of all cases of typhoid fever.

2. Prompt surgical intervention is the best and only logical treatment.

3. Early diagnosis is most desirable, and will be the means of greatly reducing the mortality, as 55 to 60 per cent. would recover.

4. Diagnosis, sufficiently early to achieve these results, can only be made by careful watching, treating all cases as serious ones and a proper interpretation of the early, even the preperforative, symptoms, the suggestions of Cushing as to this stage being of value. At the first indication of this stage have the surgeon in consultation and be prepared to operate.

5. The sphygmomanometer should come into general use as an important aid to diagnosis.

6. More cases die from delay than from errors in surgical technic. Therefore, in doubtful cases, though a mistake may be made and no perforation found, operate.

7. No case, unless dying, is so desperate as to be beyond some hope of saving. So in operating, lose no time and be sure to drain.

8. Get into the abdomen quickly and get out more quickly.

(NOTE.)—Since this paper was written, Dr. W. D. Haggard of Nashville has reported, in a paper read before the American Association of Obstetricians and Gynecologists, three cases, with three recoveries.—L. F. (See THE JOURNAL A. M. A., Oct. 17, 1903, p. 979.)

A SIMPLE, ACCURATE AND RAPID METHOD OF LOCALIZING FOREIGN BODIES IN THE ORBIT.

VARD H. HULEN, A.M., M.D.
SAN FRANCISCO.

When the eye has been injured and there is a possibility that a foreign body remains, the very first procedure is to determine, if possible, the exact location of the object in reference to the eye. If the foreign body can not be seen with the ophthalmoscope we must resort to the x-ray, and should the result of such examination be positive, we then proceed to localization before any means whatsoever are tried for its removal.

As the vast majority of the foreign bodies in eye cases (iron, steel, copper, lead, glass, etc.) are revealed by the Roentgen ray, we can usually be certain of a positive result if the foreign body be present. The circumstances attending the injury often determine the probable substance of the foreign matter present. Fortunately most of such injuries to the eye are produced by pieces of iron or steel, and as these objects are attracted by a magnet we have thus an invaluable method for their removal.

Since the advent of the incomparable giant magnet of Haab, great advancement has been made in the successful treatment of these cases, but I do not at all agree with those who advocate using the Haab magnet in an attempt to determine whether or not an eye contains such a foreign body. I do not consider it good surgery or good sense to attempt to remove a piece of steel from the eye before its exact location is known. This being so, it is most desirable to have a method of localization that is simple, that is quickly used and that is absolutely accurate.

A number of methods of localization have been advocated, but the only one to be recommended, with which I am familiar, is the method of Makenzie Davidson. In London over two years ago I had the pleasure of seeing Mr. Davidson repeatedly apply his method with excellent results. But his method requires considerable special apparatus, a good deal of time, and I find the exact details are not easy to carry in the mind. For these reasons I sought a simpler and more rapid method, and yet one equally as accurate. Since August, 1902, I have employed a method of localization which has fulfilled all the requirements. With me it is original, but I do not suggest it as a new method, for not a few things in medicine presented as new later are proven otherwise.

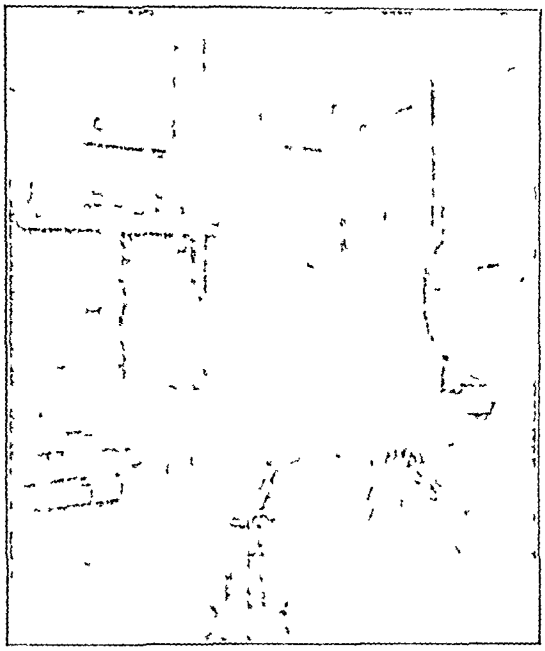

Figure 1.

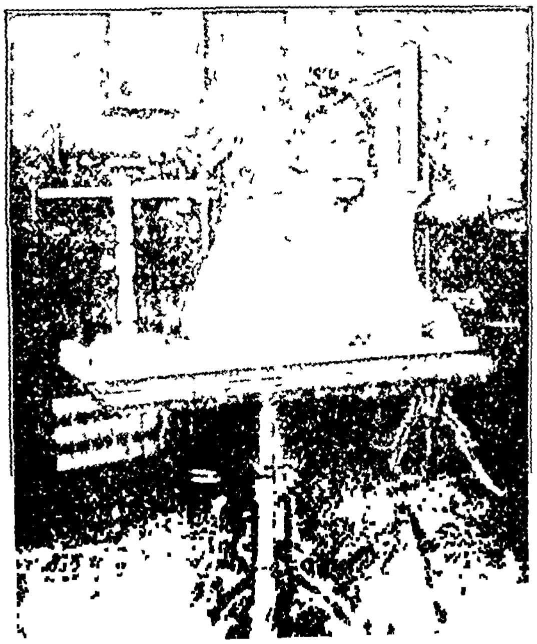

Figure 2

My "localizer" (Fig. 1) can be made by any carpenter, and the photograph presented is explanatory of its mechanism. As the head must be absolutely immovable, I have the patient hold her position firmly with her teeth, in preference to Makenzie Davidson's head fixation (Fig. 2).

The method of procedure is as follows: A piece of lead of suitable size and shape is securely fastened with adhesive plaster to the margin of the lower lid of the injured eye directly under the center of the pupil. (This marker might be fastened in the conjunctiva.) Then the distance from the upper extremity of this "marker" to the center of the cornea and also the distance the marker is anteriorly or posteriorly to the apex of the cornea is taken and recorded. A Crookes tube is next adjusted vertically in the holder of the localizer so that the luminous point of the anode and the point where the wires cross and the V-shaped sight are in a horizontal line. Then the distance from the anode to the cross wires is measured and recorded. The patient is placed in position, a photographic plate is put in the frame and Photograph 1 is taken. The patient remains in the same position, but the tube is raised a definite distance, usually three inches, and Photograph 2 is taken, and both pictures are sent to the dark room to be developed. The marker on the patient's lid is again inspected to be sure it has not shifted its position since first measured.

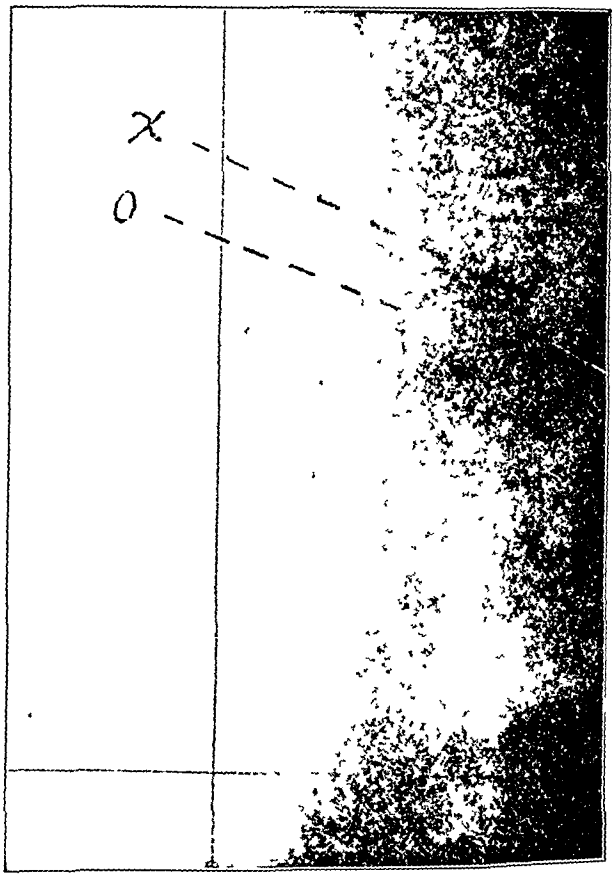

Fig 3.—Case 1. Photograph 1. X Foreign body. O Point of marker. In this photograph, as also in Figures 4, 9 and 10, the foreign body shadow has been marked over to make it more clear

With these two plates and the accurate measurements one can quickly determine the exact position the foreign body occupies in the orbit.

On a sheet of drawing paper make two vertical lines, the distance between them being that recorded for the distance between the anode and cross wires. Cross each of these lines near the bottom by a horizontal line, and mark the point of crossing of left line "1." Then mark a point "2" on this left vertical line, the same distance above as the tube was displaced vertically when taking the second picture. Then in Photograph 1 measure the vertical distance from the shadow of the *horizontal* wire to the upper extremity of the shadow of the marker, and on the right vertical line in the diagram beginning at the point crossed by horizontal line measure vertically this distance, designating that point "0, 1." In the same way measure and mark the vertical distance from shadow of horizontal wire to shadow of foreign body "X, 1." Now take Photograph 2, measure and mark shadows of the foreign body and marker on same vertical line as with Photograph 1, designating the point of the foreign body "X, 2," and that of the marker "0, 2." Then connect by a continuous straight line point "1" on left vertical line with point "X, 1," on right vertical line, also by a broken line with point "0. 1"; connect point "2" in a similar way to "X, 2" and "0.2."

It is evident that the point where the *continuous* lines cross represents the location of the "marker," and that the point where the *broken* lines cross is the exact location of the foreign body in the vertical plane. As the relation between the eye and the marker is known, draw schematically an eye according to its anatomic measurements in its correct position, using the vertical measurement previously made from the center of the cornea to the upper extremity of the marker. The location of the foreign body to the eye in the vertical and lateral meridians is thus made plain by our diagram.

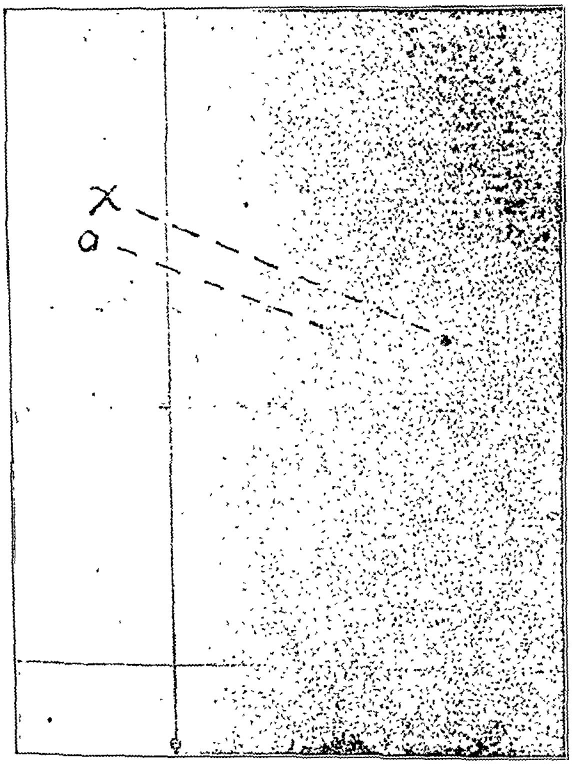

Fig. 4.—Case 1. Position 2.

Now for the upper part of the figure. Mark a point on the left vertical line "1" and also a short line at the corresponding horizontal point on the right vertical line. Then in Photograph 1 measure the distance from the shadow of the *vertical* wire to the shadow of the "marker" and mark the point of that measurement above the crossing of the short line "0', 1' "; also measure the distance from the shadow of the vertical wire to the shadow of the foreign body, and as above described, mark it "X' 1'." Connect point "1'" by a continuous line to "0,' 1' " and by a broken line "X', 1'." Then erect across the paper a perpendicular continuous line through the point corresponding to the marker and a broken perpendicular line through the point corresponding to the foreign body in the lower part of the diagram. Again it is evident that the points where these lines cross the above lines will mark the exact location of the marker and the foreign body in the horizontal plane. Again draw the eye in its correct relationship to the "marker," using the other measurement from the marker to the apex of the cornea. Thus the location of the foreign body in the relation to the eye in its horizontal meridian is revealed and the localization is complete and perfect.

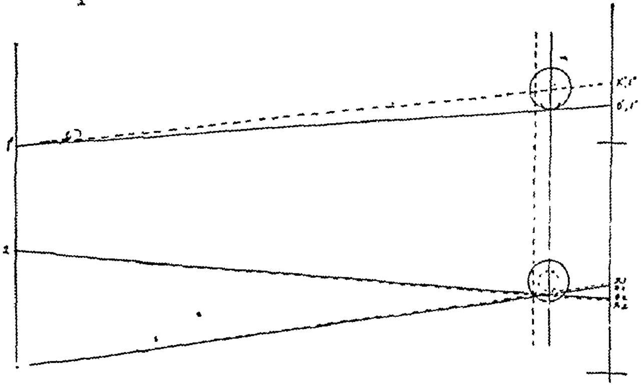

Fig. 5.—Case 1.

I need hardly say that after the idea has been grasped, one can draw this complete diagram unhesitatingly in far less time than it takes to read the description of how it is done.

Three foreign body cases are chosen from my records and reported for their interesting points, as well as to illustrate this method of localization.

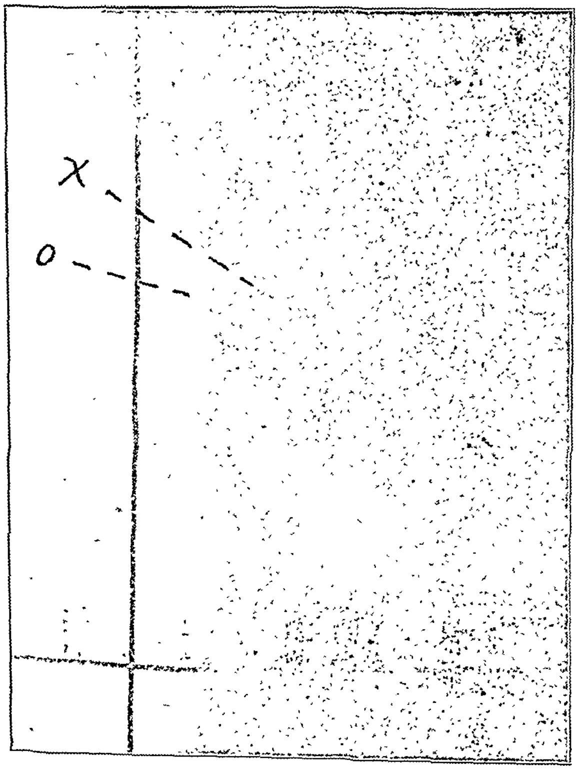

Fig. 6.—Case 2. Photograph 1.

Case 1.—Male, aged 43 years, expert machinist. Fourteen years ago he was struck over the right eye causing loss of vision of this eye from traumatic cataract. The sight of the left eye was perfect until Aug. 14, 1903, when a flying chip of cast iron from a neighboring workman's chisel injured it. He-placed himself in the care of an oculist within an hour after receiving the injury. Not much pain followed, and he was able to perform his toilet, but vision was rapidly lost. His oculist reported that at the *first examination there was a small* wound at the sclerocorneal margin below and to the temporal side, and a clot of blood or something in the vitreous to the nasal side. The patient did not believe the iron had entered the eye at all. A small magnet was applied and later the Haab magnet was tried repeatedly without any result or any sensation of pain or drawing feeling about the eye. Very slight reaction followed the injury, but he was kept under daily observation.

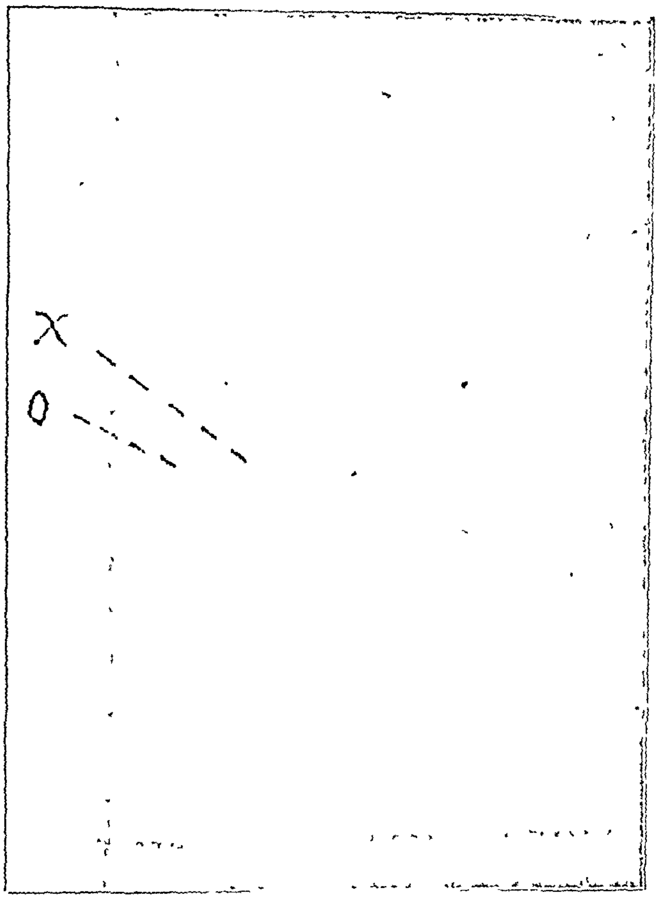

Fig 7.—Case 2. Photograph 2.

Four months later the patient consulted me. The left eye was free from pain and inflammation, a traumatic cataract obscured the pupil, a very insignificant scar marked the site of the injury. Vision =1/∞. Projection faulty. T.= —½. An *x*-ray examination showed the presence of a foreign body in the orbit.

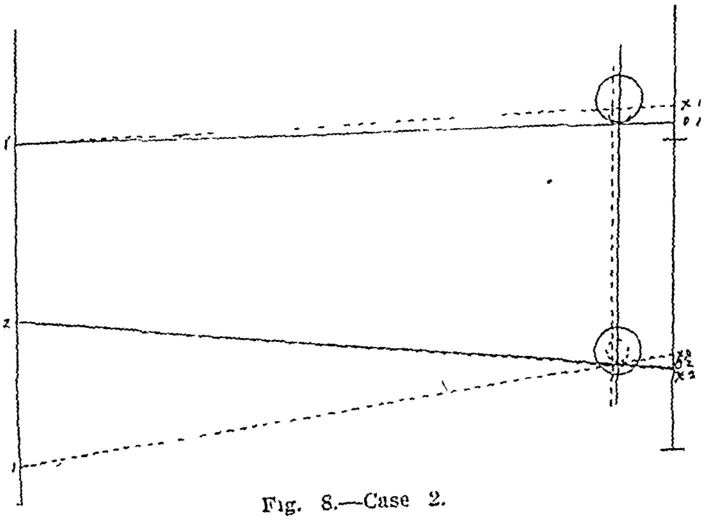

Fig. 8.—Case 2.

Localization by the method described above revealed the fact that the piece of iron was in the inner and lower part of the wall of the eye. As this condition seemed improbable I felt that some slight error had been made in my measurements, and that probably the iron was inside the eye, resting on the wall at the site shown. Then I tried my giant magnet again and again with a negative result. The patient was sent to the hospital, and next day, under chloroform, an incision, *guided* by the localization, was made with a cataract knife, cutting into the iron, but it was even then found impracticable to remove it with the magnet or forceps, and as the eye was hopelessly blind in any case, enucleation was done. Thus I became possessed of a most interesting and beautiful specimen, for the small elongated piece of iron was found to be in the wall of the globe, one point without and the other point within the eye. My localization had been absolutely accurate.

Subsequently the cataract was successfully removed from the right eye.

This case proves that the giant magnet is not at all a reliable test in the presence of an injury to the eye from iron or steel, for its negative result misled the patient's former surgical adviser, who counseled a let-alone plan of treatment.

Case 2.—Male, aged 22 years, logger in lumber camp; referred to me by an oculist confrère with the history that on March 17, 1903, while trimming a recently spliced wire rope with a hatchet, his left eye was injured by a flying particle He was treated by a local surgeon until the eye became quiet A month after the injury he had a severe pain in the other (right) eye, which led him to seek advice in San Francisco.

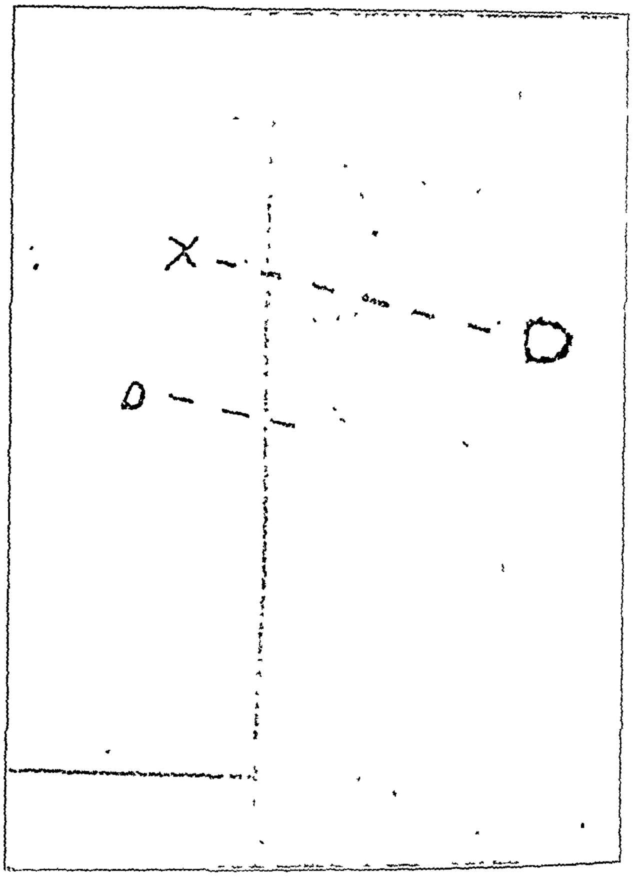

Fig. 9—Case 3. Photograph 1.

My examination, April 30, 1903, showed the right eye to be perfectly normal. In the left eye there was a small corneal opacity at upper edge of pupil, traumatic *cataract, posterior* synechia at point corresponding to corneal macula. *Vision* =3/200. Tension normal, eye perfectly quiet.

The *x*-ray revealed a small foreign body in the orbit. The repeated applications of the *Haab magnet* resulted negatively, as in Case 1.

Next day localization showed the particle to be in the eye below and slightly to the nasal side, probably resting *in the* posterior surface of the swollen lens. Not knowing the conditions I again applied the giant magnet, having the patient turn the eye as strongly upward as possible. After a moment he complained of pain; reducing the strength of the current I directed the patient to look straight ahead and then down, and the piece of steel entered the anterior chamber. A small section was made in the cornea and the foreign body was easily extracted. No reaction or change of vision followed the operation.

This case again shows the unreliability of the Haab magnet to reveal the presence of a piece of steel in the eye; it shows the accuracy of this method of localization, but—what is here most important—the exact location of the foreign body enabled me to remove it successfully with the Haab magnet, while before localization I failed.

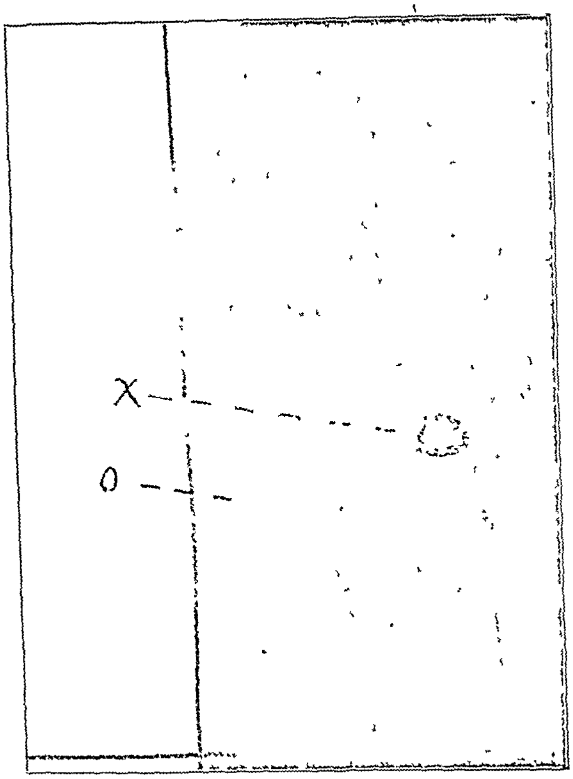

Fig 10—Case 3 Photograph 2.

Case 3.—Male, aged 36 years, blacksmith. Aug. 1, 1903, while striking, a flying piece from the sledge hammer struck him in the left eye, destroying the sight instantly. Aug 3, 1903, the patient was brought to my office by his oculist to try the effect of the giant magnet. Examination showed a penetrating wound of the cornea extending from the center downward and slightly outward 8 mm., a corresponding injury to the iris and the lens, no reflex from fundus. Vision = 0, globe soft.

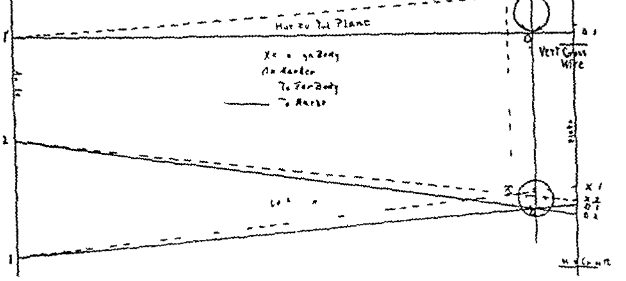

Fig 11—Case 3

The result of application of the Haab magnet to the eye in various positions was entirely negative

An x-ray photograph revealed the presence of a large foreign body in the orbit. Localization by the method detailed above showed the foreign body to be entirely outside the eye (see diagram). Although it was not necessary, enucleation was done by the oculist in charge of the case as the eye was hopelessly blind, and the healing would require the patient's detention in the hospital, etc. Thus we obtained the proof that my localization was correct; the wound of exit of the foreign body was found in the posterior and inner wall of the globe. Both the wounds of entrance and exit were as clean cut as if made with a sharp knife. The axis of one wound being almost at a right angle to that of the other, showed that the foreign body twisted on itself in its passage through the eye. The wall of the eye was unusually thin.

This case again shows the necessity of exact localization, for it seemed quite improbable under the circumstances that so large an object would go entirely through the eye.

Because of the known position of the foreign body in the orbit the eye could have remained with perfect safety had a cosmetic result been of more importance than time and expense. The piece of steel in this case was 8 mm. in one diameter by 5 mm. in the other. We knew the foreign body to be quite thin from the faintness of the shadow in the x-ray picture, as well as from the clean-cut lines of the wounds.

751 Sutter Street.

STRICTURES OF THE FEMALE URETHRA.

WITH REPORT OF CASES.*

H. L. E. JOHNSON, M.D.
WASHINGTON, D. C.

Strictures of the female urethra are narrowings of the intima of the canal of a greater or less degree, which impede or prevent the passage of the urine by the natural course from the bladder. They are congenital or acquired, single or multiple, and may be classified as stenosis or obstructive, atresia or retentive, atresia, nonretentive, when the urethra becomes occluded from disuse associated with vesicovaginal fistula and atresia with urine discharged through the umbilicus via a patulous urachus. Various modifications of these varieties are found associated with malformation of the bladder.

Congenital atresiæ are usually located at the neck of the bladder. or in the upper third of the urethra, but obliteration of the entire canal, or its absence, has been noted. Acquired cases, if traumatic, are situated at or near the site of the injury, while, if non-traumatic, they are found usually in the middle third of the urethra.

Statistics are lacking as to frequency. The few authors who mention the condition agree that it is uncommon. About twelve years ago I read a paper before a Washington society, reporting a case of acquired stenosis, with retention, calling attention to the absence of statistics, and the large number of standard authors who made no mention of the disease. Some recent text-books mention the subject only casually, while others do not mention it at all.

The causes are congenital malformation, traumatic, internal or external, associated with abnormal, prolonged or instrumental labors. Injuries of the genitals from burns, scalds, falls, cicatrices following operations and contractions from free use of caustics. Inflammation and infection from gonorrhea, urethral chancre and chancroid, septic instruments, urethral masturbation, tumors and adhesion bands in vagina. Tumors within the urethra are said never to cause stenosis or atresia.

The pathologic alterations resulting from congenital malformation, inflammation, infection, pressure and trauma, may present any degree of structural change from obliteration or occlusion of a portion, or the entire urethra with fistula and bladder ureter or kidney complication; to the simplest submucous connective tissue infiltration, restricting only slightly the lumen or elasticity of the canal.

---

* Read before the Tri State Medical Association of the Carolinas and Virginia, Danville, Va.

The symptoms of acquired stenosis resemble those of cystitis, frequent, scanty, painful or difficult urination or retention. In some instances the urine is normal, leading to error in diagnosis by directing suspicion to surrounding organs, the tubes, ovaries or uterus especially when displacement exists. The urine may contain blood, pus or mucus, and hydronephrosis may result from retention. Congenital atresia without fistula presents unmistakable physical signs of retention or distention. Atresia co-existing with fistula or other malformations has no distinctive symptom, except the closed canal.

Diagnosis is based on discovery of stenosis or atresia by the use of olive-pointed sounds, bougies or metal catheters. The condition of urine, even in advanced cases, is often misleading. Infrequency of the disease causes delay in diagnosis; therefore, no physical examination in "disease of women" should be considered complete until the catheter has been passed into the bladder.

Prognosis is favorable in acquired stenosis or atresia, except where advanced bladder or kidney disease exists from infection or distention. In congenital atresia, it will depend on the complications in individual cases.

Treatment of acquired stenosis or atresia consists in gradual or rapid dilatation with olive-pointed sounds, bougies, metal catheters, urethral or uterine dilators, and in some cases, cutting or incision. Constitutional medication should invariably follow surgical correction of stenosis or atresia from urethral chancre. Cicatricial bands in the vagina contracting the urethra should be incised, stretched and loosened up. Bladder and urethral irrigation and flushing should be practiced in all cases. Treatment of congenital atresia will depend on the extent and the character of complications. It may be necessary, in extreme distention, to puncture the bladder to evacuate its contents, or incise, making either a vesicovaginal or a urethrovaginal fistula, before opening the atresia, closing the incision or fistula after the integrity of the reconstructed urethra is assured. Atresia complicated with vesicovaginal fistula should be dilated or incised, subsequently closing the fistula. Atresia complicated with urine escape at umbilicus through patulous urachus, should be dilated or incised without making a vesical fistula. After changing the course of the urine, the patulous urachus is supposed to close and atrophy. (A patulous urachus is sometimes observed in abdominal surgery.) Reed advises as follows:

> Where atresia of the upper part of the urethra is associated with the vesicovaginal fistula, the operator may cut out the portion of the urethra and unite the neck of the bladder to the portion of the urethra below the excision. If atresia exists between a urethral fistula below and a vesicovaginal fistula above, the readiest way to deal with it is to thoroughly loosen up the tissue and bring the upper edge of the vesical fistula down to the outer edge of the urethral fistula. To unite such a fistula, however, a combination of the transverse and longitudinal operation may be done. A transverse incision may be made by making an artificial vesicovaginal fistula just above the neck of the bladder. The upper edge of this can then be stitched to the lower edge of the urethral fistula, and, after healing has taken place, the edges of the original vesicovaginal fistula can be closed by stitches placed so as to bring the edges together from side to side, leaving a longitudinal scar.

Case 1, 1892 (referred to above).—Widow, aged 23, white. Bladder trouble for several years. Many physicians consulted. Urination frequent, painful, scanty. Urine examination, sp. gr. 1022, neutral, trace of albumin, no sugar by microscope, blood, pus, but no casts. Within one week, retention of urine for 20 hours occurred, bladder became distended, violent pain with tenesmus. Metal catheter located obstruction in middle third of urethra.. Considerable force required to pass through stricture. Subsequent treatment, gradual dilatation (to 36, French scale), and bladder irrigation. History of gonorrhea several years before.

Case 2, 1893.—Single, aged 19, colored, seen at my service at Emergency Hospital. Injured and burned by explosion of shotgun between thigh when a small girl. Extensive deformity from cicatricial contraction. Vulva distorted almost beyond recognition and drawn above pubes to left side. External meatus closed to pin-point size, by cicatrix. Urine passed by drops. Incised cicatrix, removing wedge-shaped piece, and dilated. Patient never returned. Subsequent history unknown.

Case 3, 1898.—Married, aged 25, white. Resided in a southern city. Pregnant six months, had supposed ovarian tumor, operation had been advised. Consulted me, February, 1898. Complained of frequent, painful, scanty urination since childhood. Examination in office. Pregnancy determined, together with a tumor size of a cocoanut, sensitive and fluctuating, located on the right side of the uterus. Introduced metal catheter, locating stricture two and a half inches from meatus, admitting small whalebone bougie, gradually dilated stricture and forced silver catheter through obstruction, urine escaping constantly. Tumor promptly disappeared. Gradually dilated to 36 (French). I could learn no cause for stricture. Patient returned to her home and was delivered by her regular physician. I have recently learned that there has been no subsequent trouble. The tumor had every appearance of being ovarian, until urine was drawn.

Case 4, 1900.—Single, aged 28, white. Neurasthenic, almost a nervous breakdown. Bladder weakness since infancy, almost incontinence. Still wets the bed at night. Been in sanitarium for spinal irritation, painful coccyx and hysteria, urine normal. Examination showed a small caruncle, urethra inflamed. Two strictures found at middle third. Gradual dilatation. Improved in health promptly. Nervousness disappeared. Complete control of bladder day and night. Patient now entirely well and married.

Case 5, 1903.—Single, aged 38, white. Pelvic symptoms for past 20 years. Polypus uteri, frequent, painful urination. Disturbed frequently at night. Polypus removed, uterus curetted. Urethra explored under ether. Five strictures of various degrees found. Rapid dilatation. Patient apparently restored to perfect health.

Case 6, 1903.—Single, aged 39, white. Always in bad health. Under physician's care more or less all her life. Uterine disease for many years. Urination frequent, scanty, painful, often wets the bed. Urine always reported to be normal. Menses almost constant, profuse, with clots. Examination, uterus enlarged, anteflexed, marked pelvic adhesions, cervix eroded. Under ether broke up pelvic adhesions, curetted uterus, explored the urethra, discovering two small strictures close together at middle third. Rapid dilatation. Patient has been steadily improving in health. All old symptoms have disappeared.

1821 Jefferson Place.

Poisoning by Honey.—The occurrence of severe poisoning following the ingestion of honey calls attention to the possibility of the collection by the bees of the active principles of some plants. Gelsemium and powerful narcotics thus have been the causes of giddiness, cardiac weakness, pruritus, amaurosis, edema of the glottis and even death. The occurrence is rare, but is to be remembered in view of the fact that the etiology in cases presenting some of these symptoms may not be readily discovered.

TAHITI FROM A MEDICAL STANDPOINT.

N. SENN, M.D.

Head of the Department of Surgery, Rush Medical College, in Affiliation with the University of Chicago.

CHICAGO.

Very few people who left the schoolroom twenty-five years ago would be able to locate Tahiti, and many of them have even forgotten the name. The children fresh from school recall it in connection with the difficulty they encountered in finding the little dot in the great trackless South Pacific Ocean, surrounded by a group of still smaller islands, called the Society Islands, so named in honor of the Royal Society of London by the famous explorer, Captain Cook.

Tahiti is nearly 4,000 miles distant from San Francisco, in a southwesterly direction below the equator, in latitude 17, hence in a latitude similar to that of the Hawaiian Islands, which are situated about the same distance north of the equator.

I had heard much of the beauty of this far-off island, and decided to spend my midwinter vacation by paying it a visit. Formerly the passage from San Francisco had to be made by a schooner, which required several months. For the last three years the island has been made readily accessible by a regular steamer service. The staunch steamer *Mariposa* of the Oceanic Steamship Company of San Francisco sails from that port every thirty-six days, makes the trip in twelve days, and remains at Papeete, the capital of the island, four days, which gives the visitor ample time to visit the most interesting points and make the desired observations.

The track of the steamer is over that part of the Pacific Ocean which is comparatively free from violent storms, between the storm centers east and west from it. The trade winds cool off the tropical heat in the vicinity of the equator, rendering the voyage at all seasons of the year a pleasant one. I know of no better way to spend a short midwinter vacation than a trip to Tahiti, the island paradise, the most interesting and beautiful of all islands. The twenty-five days of voyage on the ocean, the few days on shore, occupied by a study of its natives, their customs, manner of living, visits to the various points of historic interest, and the greatest of all genuine pleasures, the contemplation of nature's choicest exhibitions in the tropics, are best adapted to procure physical rest and pleasure, and pleasing as well as profitable mental occupation.

No writer has ever done justice to the natural beauties of this island gem of the South Seas. The towering mountains, the tropical forests, the numerous rippling streams of crystal water, shaded dark ravines, the palm-fringed shore, the lagoons with their quiet, peaceful, clear waters painted in most exquisite colors of all shades of green, blue and salmon, their outside wall of coral reef ceaselessly kissed by the caressing, foaming, moaning surf, the nearby picturesque island of Moorea, with its precipitious rugged mountains rising from the sea, the flat, basin-like, palm-clad atolls in the distance and the vast ocean beyond, all are pictures of which the mind never tires, and which engraft themselves indelibly on the memory.

The peaceful, quiet, sleepy little island is an ideal place for physical and mental rest. Nature has provided so well for the natives that labor on their part is rather a matter of choice than necessity. The few European and American inhabitants soon lose their inborn energy under the soothing and somewhat relaxing influence of the tropical climate, and limit the hours of their work to a minimum. The entire population, the laborer, the mechanic, the merchant, the rich and the poor, rest from ten until noon, and the doors of every shop are closed at five in the afternoon. The visitor will do well to follow the example of the natives, and devote the midday hours, the hottest of the day, to rest, and a short after-breakfast siesta.

THE CLIMATE.

The climate of Tahiti, although tropical, is favorably influenced by the trade winds and frequent showers. The breezes from ocean and land keep the heated atmosphere in motion most of the time, day and night. The entire island, from shore to the highest mountain peaks, is covered by forests and vegetation, which retain the moisture and attract the clouds, securing throughout the year a sufficient rainfall to feed the numerous mountain streams and water the rich soil of the mountain sides, valleys and lowlands along the shore. The temperature seldom exceeds 90 F., and during the coldest months, March and April, it occasionally falls as low as 65 F. The atmosphere is charged with humidity, and when this condition reaches the maximum degree the heat is oppressive, more especially when there is no land or ocean breeze. Papeete, partially inclosed by mountains, and on the leeward side of the island, is said to be one of the warmest places in the island.

Tahiti's summer time is our winter. I was fortunate in visiting the island during the latter part of January, which is the spring time there. It was the time when Nature makes a special effort to produce the luxurious tropic vegetation after the drenching rains of December. It was the time when the evergreen trees cast off here and there a faded leaf to be replaced by new ones from the unfolding buds. It was the season of flowers and the greatest varieties of fruits. For a winter vacation the months of January and February offer the greatest inducements. Those who are in need of a real rest and are fond of a long ocean voyage and enjoy tropic scenery and the wonderful products of the fertile soil of the tropics, should not fail to visit Tahiti, the little paradise built in the midst of the vast expanse of the Pacific Ocean.

INHABITANTS.

It was my privilege during my brief stay in the island to meet Tati, chief of the Papara district. He is a direct descendant of one of the two noble families of the island, the Tevas, and one of the most prominent and influential citizens of the colony. I asked him to what race the Tahitians belonged. He had a ready reply. He said: "We belong to no race; man was created here; this is the Garden of Eden." There is much force, if not truth, in this expression when we take into consideration the charming beauty of the island and the wonderful provisions which Nature has made here for the existence of man. Then, too, the Tahitian is a good specimen of manhood, intellectually and physically, far superior to the negro race and the Mongolian. The Tahitians are Polynesians, like the inhabitants of most of the islands in the South Seas, and there can be but little doubt that the Polynesians belong to the Malay race, having migrated from island to island, from west to east. The invasion of the island by so many Europeans during the last century has done much to destroy the original, genuine Polynesian type of its inhabitants, more especially of those who live in Papeete, the only city in the island. In the remote country districts the purity of the native blood has been preserved to a greater extent, as well as the primitive customs and habits of the people.

In stature the Tahitian compares well with any other race. The face is expressive of more than ordinary intelligence. The aquiline nose is commonly seen among them, and there are many varieties both of hair and complexion. In complexion they resemble more nearly the Japanese than the Chinese. The beard is thin, the prevailing hair jet black, straight or wavy and long; eyes large and black; no drooping or obliquity of the eyelids. Their face is generally roundish; no unusual malar prominences; forehead slightly receding, mouth large, lips thick, wide nostrils, ears large, chin well developed. Much has been said about the beauty of some of the women of the South Sea islands, but I am sure I do them no injustice if I say that these descriptions are overdrawn by sentimental writers and do not correspond when put to the test of comparison with the reality. Old European residents of Papeete agree in that the morality of the natives has not improved since they have been under the influence of civilization forced on them by the European invaders. The greatest fault of the people is their incurable laziness, a vice for which they are not entirely responsible, as Nature has provided so bountifully for their needs.

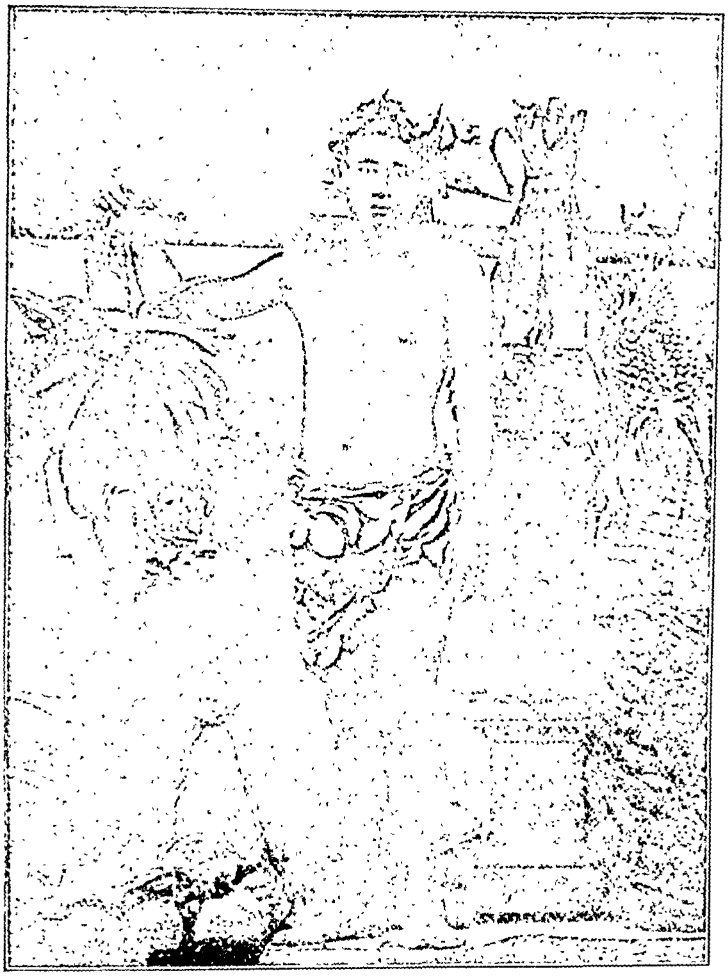

Fig. 1.—Type of Tahitian.

Robbery, stealing and murder are almost unknown; petty thefts, on the contrary, quite common. The people, young and old, are affable, extremely courteous and hospitable to a fault; the family ties strong and extending to the remotest relatives

FRIGHTFUL NATIVE MORTALITY.

The immediate effect of the European civilization on the health and lives of the natives was frightful. On this subject I will let Ariimaitai, a lady of noble birth and mother of the present chief of Papara, speak: "When England and France began to show us the advantages of their civilization, we were, as races then went, a great people. Hawaii, Tahiti, the Marqueses, Tonga, Samoa and New Zealand made a respectable figure on the earth's surface, and contained a population of no small size, better fitted than any other possible community for the condition in which they lived. Tahiti being the first to come into close contact with the foreigners, was first to suffer. The people, who numbered, according to Cook, 200,000 in 1767, numbered less than 20,000 in 1797, according to the missionaries, and only about 5,000 in 1803. This frightful mortality has been often doubted, because Europeans have naturally shrunk from admitting the horrors of their own work, but no one doubts it who belongs to the native race. Tahiti did not stand alone in misery; what happened there happened everywhere, not only in the great groups of high islands, like Hawaii, with three or four hundred thousand people, but in little coral atolls which could only support a few score. Moerenhaut, who was the most familiar of all travelers with the islands in our part of the ocean, told the same story about all. He was in the Austral group in 1834.

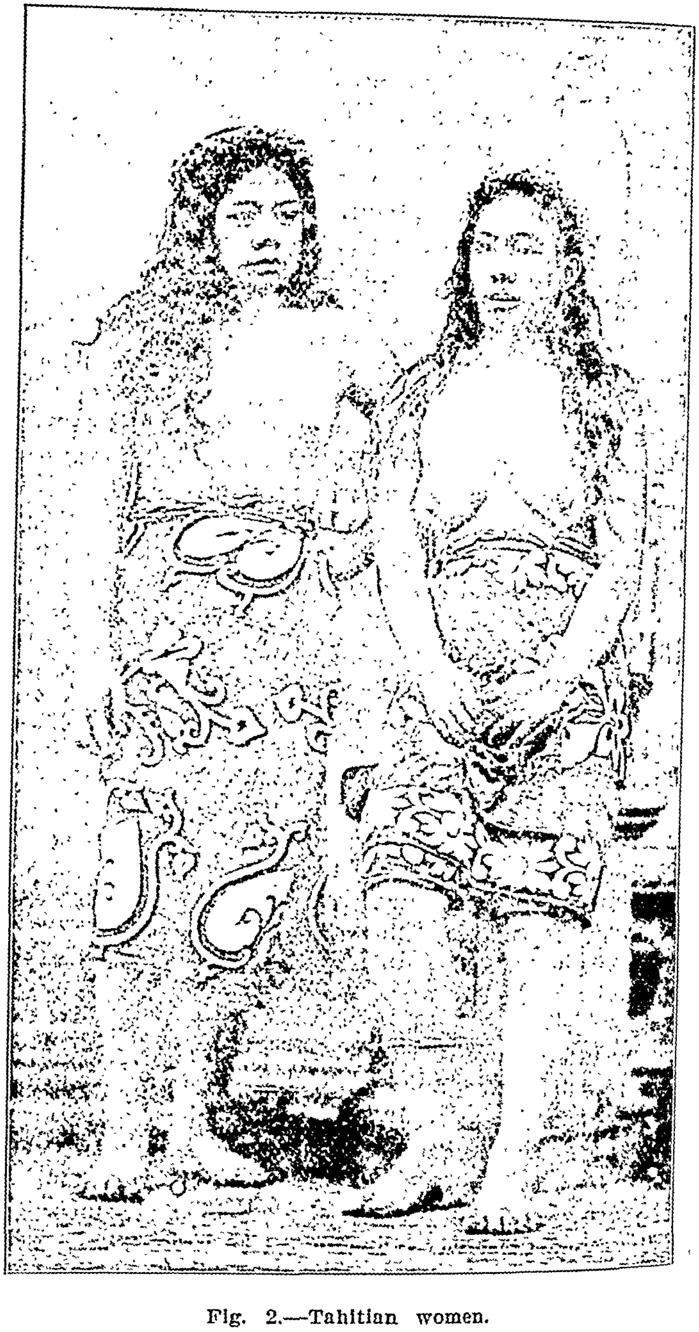

Fig. 2.—Tahitian women.

"At Raivave he found ninety or one hundred natives rapidly dying, where fully 1,200 had been living only twelve or fourteen years before. At Tubuai he found less than 200 people among the ruins of houses, temples and tombs. At Rurutu and Rimitara, where a thousand or twelve hundred people had occupied each, hardly two hundred were left, and while nearly all the men had died at Rimitara, nearly all the women had been swept away at Rurutu. The story of the Easter Islanders is famous. That of the Marqueses is about as pathetic as that of Tahiti or Hawaii. Everywhere the Polynesians perished, and to him it mattered little whether he died of some new disease or from some new weapon, like the musket, or from misgovernment, caused by foreign intervention. No doubt the new diseases were most fatal. Almost all of them took some form of fever, and comparatively harmless epidemics, like malaria, became frightfully fatal when the native, to allay the fever, insisted on bathing in cold water. Dysenteries and ordinary colds, which the people were too ignorant and too indolent to nurse, took the proportions of plagues. For forty generations these people had been isolated in this ocean, as though they were in a modern sanatorium, protected from contact with new forms of disease, and living on vegetables and fish. The virulent diseases which had been developed among the struggling masses of Asia and Europe found a rich field for destruction when they were brought to the South Seas. Just as such pests as lantana, the mimosa or sensitive plant, and the guava have overrun many of the islands, where the field for them was open, so diseases ran through the people. For this, perhaps, the foreigners were not wholly responsible, although their civilization certainly was; but for the political misery the foreigner was wholly to blame, and for the social and moral degradation he was the active cause. No doubt the ancient society of Tahiti had plenty of vices and was a sort of Paris in its refinements of wickedness, but these had not prevented the islanders from leading as happy lives as had ever been known among men."

These are strong words, but they are nevertheless only too true. Civilization brings to savage races curses as well as blessings. The primitive people are more receptive for new vices than new virtues. In 1880 the number of inhabitants had again increased to 13,500, but since that time it has been reduced to 11,000, as shown by the last census. The rapid depopulation of the island was caused by the introduction of new acute infectious diseases, such as measles, whooping cough, la grippe, etc., which among these people was attended by a fearful mortality. It was only last year that an epidemic of measles, a trifling disease with us, claimed several hundred lives and extended to nearly all of the islands of the entire group. The disease that is now threatening the extinction of the race in a short time is pulmonary tuberculosis. The natives are extremely susceptible to this disease, and the small native houses, crowded with large families, are the breeding stations for the infection. The French government has at last recognized the need of taking active measures to improve the sanitary conditions of their colony and protect the natives against the spread of infectious diseases. A corps of three physicians, sent by the French government on this mission, made the voyage from San Francisco to the island on the steamer *Mariposa* with me. The names of these physicians are: Dr. Grosfillez, surgeon major of the first class of the colonial troops; Dr. H. Rowan, a graduate of the Pasteur Institute, and Dr. F. Cassiau, of the clinic of Marseilles. The military surgeon receives an annual salary of $1,500, the two civil doctors $1,200 each. They are under contract for five years. They have been given judicial power to enforce all sanitary regulations they see fit to institute. They will be stationed at different points and will establish a requisite number of lazarettos, something which will fill a long-felt and pressing need.

(*To be continued.*)

THE INFLUENCE OF DENTAL DISEASE ON THE ETIOLOGY OF CERTAIN OCULAR DISTURBANCES.

WILLIS O. NANCE, M.D.
Oculist and Aurist to Cook County Hospital; Assistant Surgeon, Illinois Eye and Ear Infirmary.
CHICAGO.

That dental caries and its allied processes figure to a considerable degree in the etiology of certain ocular disorders seems to have been generally recognized by those who have made this subject a matter of careful observation. Difficult early dentition, also, has long been considered in the same light, and as far back as 1824, Travers[1] called attention to strabismus as a symptom sometimes arising from this cause. Galezowski,[2] the eminent French ophthalmologist, has, for several decades, enthusiastically supported the theory of dental causation of various eye troubles, and many of the ablest contributions to the literature of this subject are from his pen. So strongly imbued with the teachings of his confrère was Weinberg,[3] that he expressed the belief that during a nine months' dispensary service he saw 188 cases of ocular disturbance dependent on morbid dental changes. Henry Power,[1] in 1883, read a meritorious paper on the subject before the Odontographical Society of Great Britain, and more recently Knies,[4] Bull,[5] Davis,[6] Weill[7] and others of our own country, have contributed valuable data. The text-books of ophthalmology and dentistry in general use, as a rule, however, devote little or no space to its consideration, and the matter does not appear to have received its deserved attention in the deliberations of scientific bodies or in the classroom.

The anatomic relations existing between the alveoli and teeth and the orbit and its contents are so intimate that one can readily appreciate how morbid changes of the one may influence, either by continuity or by so-called reflex manifestation, the functional relations of the other. As concisely indicated by Despagnet,[8] "the same periosteum which lines the orbital cavity extends to the alveolar border of the upper jaw; the mucous membrane of the mouth is in direct continuation with the conjunctiva. Many times the roots of the upper teeth extend directly into the antrum of Highmore, and from this situation disease frequently reaches the orbit through the thin partition of bone. The angular artery and certain veins run almost directly from one region to the other. The same general nervous supply reaches both, not only through the fifth pair, but also through the sympathetic system."

[8] Recueil. d'Oph , July, 1900. (Abst. Ann. of Ophth., 1900.)

Among the ocular disorders that various writers have ascribed to dental disease as a causative factor are orbital cellulitis and abscess, conjunctivitis, keratitis, corneal ulcer, iritis, scleritis, papillitis, mydriasis, lachrymation, amaurosis, amblyopia, strabismus, ptosis, interference of accommodation and paresis or spasm of the several muscles of the eye and lids.

According to statistics compiled by Schwendt,[9] of 44 cases of orbital cellulitis, more than 15 per cent. resulted from dental caries. Hirsch[10] has since collected 25 cases of orbital abscess of dental origin, and other writers, notably Hildreth,[11] Burnett,[12] Vossius,[13] Fage,[14] Snell,[15] Juler,[16] and Galezowski,[17] have reported representative cases of the same disease of like origin. Burnett's case followed an unsuccessful attempt to extract an upper canine tooth, and resulted in total loss of vision. Snell's case, following the extraction of two upper decayed teeth for alveolar periostitis in a girl of 14, terminated fatally, and total destruction of the eye in Juler's case necessitated enucleation.

An additional case of abscess of the orbit, which fortunately had a more favorable outcome than those just cited, and which resisted treatment until attention was directed to the teeth, came under my care early in the year 1899.

Mr. H., aged 28, farmer, had been suffering intensely from pain in the region of the right eye for nearly two weeks. The lids were markedly edematous, the eye protruding and deeply injected, the pupil dilated, and the eyeball but feebly movable. Iced applications, leeching, and hypodermatic injections of morphia had but temporarily relieved the pain and given the patient little sleep, the inflammatory process meanwhile increasing in intensity. On the second day under observation it was noted that the cheek on the corresponding side was swollen, and questioning elicited the information that the patient had suffered periodically for several weeks from a diseased tooth. Extraction of a badly decayed molar was immediately followed by the escape of a quantity of pus, and antiseptic treatment brought about a rapid amelioration of the orbital and ocular symptoms.

Numerous cases of ocular disorders of reflex dental origin have been reported from time to time. Cafe,[18] DeWecker,[19] Sloggett,[20] Brucke,[21] Gaine,[22] Alexander,[23] DeWitt,[24] Allport,[25] Turner,[26] Coleman,[26] Stevens,[27] and Widmark[28] have recorded instances of amaurosis in which dental disorders have figured as important causative factors. Power, in his article cited above, reviews a typical case occurring in the practice of Sir William Lawrence of a man 30 years old, who suffered blindness for a period of thirteen months, which was restored by the extraction of an upper first molar. Examination of the tooth revealed a small splinter of wood, one-fourth of an inch long—undoubtedly the fragment of a toothpick—that had traversed the center of the decayed root, and had been retained. Palido,[29] Park,[30] and Despagne[8] have also cited cases of amblyopia due to dental disease.

Interference with the normal accommodation of the eye has been traced to morbid dental changes by Schmidt-Rimpler,[31] Ely,[32] Nuel,[33] Galezowski,[34] Knies,[35] Dunn,[36] and Bull.[37] Schmidt-Rimpler, in the examination of 92 patients suffering from dental disease, found the range of accommodation lessened in 78 per cent. Mydriasis is another condition frequently resulting from the same cause. Galezowski[38] was so impressed with this fact that he expresses the belief that dental changes are responsible for eight of ten cases of third nerve paralysis, instead of its being an invariable index of syphilis, as is generally supposed.

Several months ago Mrs. F., aged 38, was sent to me by her family physician. She had complained of severe headaches and inability to read or sew for a period of eight or ten weeks. The right pupil was widely dilated and there was no response to light stimulation. Patient was wearing weak convex lenses which had been "fitted" by a local optician. Examination revealed compound hyperopic astigmatism of both eyes, and the correction was ordered for constant use. Ophthalmoscopic examination was negative. There was no history of syphilis. Potassium iodid had been administered for several weeks in increasing doses to a maximum of 200 grains per diem, with no improvement. Examination of the teeth demonstrated a sensitive upper molar which presented a cavity of considerable proportions in which rested the remains of an amalgam filling. The tooth was properly treated, and within a fortnight the mydriasis had entirely disappeared

Ely,[39] Gill[40] and Desmarres[41] have reported like instances where the mydriasis disappeared with appropriate dental interference.

Various muscular anomalies have been attributed to dental disease by Hancock,[42] who cites a case of divergent strabismus and ptosis; Boyd-Wallis,[43] blepharospasm; Terrier,[44] "obstinate spasmodic contraction of the motor muscles of the eyelid"; Mumery,[45] strabismus; Power,[46] bilateral ptosis; Ely,[32] cases of paresis of orbicularis with diplopia and paresis of a rectus and the ciliary muscle; Juler,[47] "persistent jactitation of eyelids"; Hutchinson,[48] cases of spasm of eyelid and lagophthalmus, and Snell,[49] proptosis.

Many of the common inflammatory disorders, both extraocular and intraocular, seem to depend on dental causation in a fair percentage of cases. During the past two years I have seen two of the former—one of episcleritis—the other conjunctivitis—accompanied by supraorbital pain, ciliary tenderness and simulation of sympathetic irritation.

A man of 48 years came to my clinic presenting a well-marked localized injection of the sclera of the left eye. This condition had developed, according to a statement volunteered by the patient, simultaneously with an attack of toothache

several months previously. The further observation had been made that, as the odontalgia moderated in severity the eye symptoms gradually disappeared only to return when the dental disturbance recurred. So evident was the connection that the patient suggested the relationship at the first visit. On examination, the man was advised to have several roots extracted, and on submitting to the operation, was permanently relieved of the ocular trouble.

The other case was that of a girl, 16 years old, who came under my service at the Illinois Charitable Eye and Ear Infirmary. Six months previously she had been under my care on account of a scissors blade injury of the right eye, which destroyed the vision and left a scar extending almost entirely across the cornea. On her appearance at the infirmary she complained of intense supraorbital neuralgia and pain in the left eye so severe that she had been unable to sleep but little for forty-eight hours. The conjunctiva was deeply injected and there was ciliary tenderness and diminution of the power of accommodation. So distressing were the symptoms that sympathetic ophthalmitis at once suggested itself, and the patient was put under careful observation. The following day a slight swelling of the left cheek was noticed; the patient was sent to a dentist with the result that on proper treatment being applied to several upper teeth the ocular symptoms were promptly and permanently relieved.

Wright,[50], more than thirty years ago, published the history of a case of "sclerotitis" with profuse lacrymation that resisted treatment until a carious tooth was extracted, "when the inflammation subsided as if by magic." Ely,[32] relates a case of ulcer of the conjunctiva, undoubtedly of dental origin; White,[51] one of keratitis; Marlow,[52] three of "corneal congestion"; Hern,[53] scleritis; Nuel,[54] a case of conjunctivitis and ciliary injection; Colyer[55] and Roberge,[56] each one of corneal ulcer; Patterson,[55] a case of conjunctivitis with lacrymation; Galezowski,[57] Herman,[58] Despagnet,[59] Hirsch,[60] each a case of optic neuritis, and Feuer,[61] two of the same; Sous,[62] a case of keratitis punctata and choroiditis; Bull,[37] one of phlyctenular ulcer; Gill,[63] iritis and scleritis; and Milliken,[64] a case of iritis.

The number of cases which a review of the literature demonstrates, and my observations in the cases cited, leads to the belief that in dental disease is to be found an etiologic factor of more than passing importance in many ocular disturbances, and suggests the necessity of a thorough examination by a competent dentist in those instances presenting uncertain causative phenomena. A painstaking examination and intelligent surgical treatment will, in many cases, assist in elucidating various etiologic manifestations, and bring about permanent relief of the existing ocular trouble.

No Race Suicide in Texas.—The *St. Louis Medical Review* declares that the birth rate in Texas is almost twice that of the death rate, and declares that the population of Texas is growing at an astonishing rate. In one particular county the deaths exceeded the births, which was explained by the fact that that county included San Antonio, a health resort for consumptives, many of whom die.

Clinical Report.

TENIA NANA: REPORT OF TWO CASES.

H. M. HALLOCK, M.D.
Captain and Assistant Surgeon U. S. Army.
FORT PORTER, BUFFALO, N. Y.

The following cases are reported as of interest, because the parasite is considered very rare in this country:

CASE 1.—Private J. W. M., Company M, First Infantry, admitted Jan. 14, 1904. Patient states that he served in the Philippines from May, 1901, until April, 1903, and that he contracted amebic dysentery in December, 1903, from which he never fully recovered, remaining pale and weak with capricious appetite and irregular bowels; that the passages have averaged two to four a day, and have usually contained mucus; that occasionally the diarrhea has ceased for a few days, and he has then been troubled with constipation, and that he has had frequent attacks of pain in the upper part of the abdomen, at times so severe as to cause profuse sweating.

Examination on Admission.—Nothing worthy of note was found except a fairly well-marked anemia with thick pasty facies. Body fat is well retained, but patient appears to have lost much strength, and is unable to get through the day's work satisfactorily.

Microscopic examination of the stools showed numerous round and slightly oval ova about 35 microns in diameter, having a clear outer circle without radiations, but occasionally marked by irregular wavy tracings and showing in the center four parallel lines, the two outer with a slight angle and thickening at about one-third their length, and the two central ones with a slight dot at the same point, but nearly straight.

Treatment.—Male fern followed by castor oil brought away about 50 worms measuring 10 to 15 mm. in length, the head having a retractile proboscis with a single row of about 24 hooklets, and back of these 4 suckers. The segments numbered from 50 to 150, and increased greatly in size toward the tail, those fully developed containing myriads of ova and measuring in width several times their length.

CASE 2.—Private F. A. F., Company I, First Infantry, admitted Jan. 27, 1904. Diagnosis staphylococcus infection of trivial wound on the little finger of the right hand. He served in the Philippines from February, 1902, until May, 1903, and while there had two short attacks of diarrhea. He has been well since he returned to the states, except for occasional abdominal pain, which he attributed to indigestion.

Examination.—The physical examination was negative.

The routine examinations of the stools as made for all patients showed ova as in the first case, and the same treatment brought away over one hundred worms. Owing to the difficulty of recognizing these minute cestodes in the stools, I have no doubt that many hundreds were present in each case.

Comments.—The method which so far has proved most satisfactory in finding the parasites is to dilute the stool with a considerable quantity of water, and then to run it out in a very thin layer on a large plate of window glass having a black background and placed in a strong light, the examination being made with a large reading glass. The worms appear as very minute translucent or opalescent shreds not unlike mucus, and the greatest care is required lest they be overlooked. The ova are found with the microscope much more easily than the worms themselves, a two-third objective being ample after one becomes familiar with their appearance. The spread should be very thin, and but little light admitted from the condenser.

Gray Hair Versus Baldness.—Marcel Baudouin of Paris has made a discovery. He will not announce what it is until the consensus of opinion has confirmed the assumption which he has recently proclaimed that persons whose hair turns prematurely gray never grow bald, while persons who are bald never are prematurely gray. If this assumption be confirmed he thinks he can explain the reason for the facts observed.

LET YOUR INFLUENCE BE FELT.

Every member of the medical profession should be sufficiently interested in the Pure Food Bill, now before the United States Senate, to take the trouble to write to the two senators of his state urging them to vote for it. There is an opportunity for the profession to make itself felt in a good cause. Why not do it? It should not be forgotten that, in this instance especially, delays are dangerous.

Read the bill on page 910, and then act.

THE CAUSE OF YELLOW FEVER AGAIN.

The investigations of Reed, Carroll and Agramonte into the causation of yellow fever, which are fresh in the minds of all, seemed to be so universally convincing that we naturally expected any further researches in that domain to follow along the lines laid down by them, and to be concerned with the nature of the ultramicroscopic virus which their experiments indicated as the causative agent of this disease. Interest in the various bacteria described by different observers as the cause of yellow fever has waned since the publication of the experiments of the American Commission and it is therefore somewhat surprising to find new evidence being brought forward now for the *Bacillus icteroides* of Sanarelli and to hear the statement made that this is recognized by almost the whole scientific world as the cause of yellow fever. Ivo Bandi of Brazil gives in the *Zeitschrift für Hygiene*[1] the results of his studies and experiments in this field and asserts that they confirm in all essentials the views of Sanarelli. The article in question is written in an unfortunately partisan spirit, reminding one of Sanarelli's attitude toward his opponents, but the researches embodied in it are interesting and merit attention, though it is a question whether they materially strengthen the weak points in Sanarelli's position.

It will be remembered that the claim made by Sanarelli[2] that he had discovered the cause of yellow fever in the *Bacillus icteroides* was based on the following assertions: It was found in 58 per cent. of the bodies of patients dying of yellow fever; had special cultural characteristics; could be used to produce experimental yellow fever in animals; the serum of immune animals and convalescent patients agglutinated the bacillus, and that of immune animals had prophylactic and therapeutic properties against yellow fever; the germ-free filtrate of cultures produced typical yellow fever in man.

Many investigators assert that they have confirmed these statements of Sanarelli; nevertheless the organism has never won for itself an undisputed place. The objections urged against Sanarelli's assertions are that the *Bacillus icteroides* can be isolated in only a few cases, and then in very small numbers—even Sanarelli's 58 per cent. is a small percentage. Investigators working with cultures obtained from Sanarelli or his followers are unable to repeat the former's experiments as to characteristic lesions produced in animals by inoculation or as to agglutination. The cultural peculiarities are found to be variable and such as might belong to a member of the hog cholera or colon groups. The human experiments of Sanarelli were not adequately controlled, for as Novy[3] pointed out, we know nothing of the effect of intravenous injections of filtered cultures of typhoid or colon bacilli. A strong argument against the causative rôle of this organism is that it is very resistant to cold, enduring, without loss of virulence, three days of freezing, while yellow fever is a disease of warm climates and vanishes with the first frost.

The researches of Bandi should, if they are to justify the assertions made in the opening paragraphs of his article, serve to refute the above objections, and this he endeavors to make them do. To the objection that the *Bacillus icteroides* can so seldom be isolated and when isolated is found in such small numbers, he answers that it resembles the tetanus bacillus in producing a very powerful toxin while multiplying only to a limited extent; yellow fever is a toxemia. Yet he was unable to prove the presence of such a toxin by injections into animals of the blood and organs from the bodies of yellow fever patients, although these animals are susceptible to the *Bacillus icteroides.* Novy had already found that it was necessary to use an enormous dose, 20 c.c., of the filtered culture, to cause death in a guinea-pig in twenty-four hours. Bandi succeeded in isolating the organism in about as large a percentage of cases as did Sanarelli, twelve out of twenty autopsies. Its habitat within the body, however, he was unable to discover, for there are no characteristic focal lesions which can be attributed to it. His experiments on dogs were very successful and constitute the most striking part of his paper. By intravenous injections in dogs, he produced all the typical symptoms of yellow fever, with the exception of jaundice, and after death found fatty degeneration and necrosis of the liver cells, more extensive than that produced by any known organism.

Opposed to these experiments of Bandi are those of Novy, Agramonte[4] and Havelberg,[5] all of whom found no lesions in the organs of dogs injected with the bacillus in question which could not be produced by other organisms, as, for instance, certain strains of *Bacillus coli.* Bandi finds, contrary to the experience of Sanarelli, that the blood of yellow fever convalescents and immune animals does not agglutinate the *Bacillus icteroides,* which in this respect resembles the Klebs-Loeffler bacillus. Havelberg, on the contrary, found that it was easy to produce an agglutinative serum in animals, but that the serum of yellow fever patients had no such property. His criticism of the work of Reed, Carroll and Agramonte, based on his own failure to produce yellow fever experimentally in human beings by the bite of the *Stegomyia fasciata;* on the assertion that the distribution of the stegomyia does not entirely correspond to that of yellow fever; on the history of epidemics which seemed to have no relation to this insect; on the apparent conveyance of yellow fever through infected clothing, etc., remind one of the arguments used at first against the theory, now universally accepted, of the agency of the mosquito in the spread of malaria. A more serious objection is that which he makes to the experimental production of yellow fever in man, by the injection of filtered serum, on the ground that the filter used by Reed and Carroll was a Berkefeld, which allows the *Bacillus icteroides* to pass through. To this the answer may be made that the filter in question had been tested and found to hold back all demonstrable bacteria, nor would an exposure to a temperature of 55 degrees for ten minutes be sufficient to kill the bacillus of Sanarelli, which is as resistant to heat as the typhoid bacillus, yet this procedure was sufficient to destroy the virus in the serum, according to Reed and Carroll. The work of Bandi can not be regarded as having strengthened the cause of *Bacillus icteroides.*

SURGICAL TREATMENT OF MOVABLE KIDNEY.

A continued interest in this subject is shown by the number of clinical studies of large series of cases which are reported each year. Movable kidney is undoubtedly very common, and the symptoms which co-exist with such movability, or are caused by it, are sources of discomfort and disability to many women. That the condition is not an easy one to treat successfully is shown by the differences of opinion as to the best method of treatment. Since nephropexy was introduced by Hahn in 1881, various opinions have been expressed with regard to the advisability of operation. At first, as is often the case after the introduction of a new operation, many surgeons were enthusiastic in stitching up every movable kidney they could find. This operation furore led to more careful examination of cases, and showed how prevalent the condition is, some observers estimating that sixty or eighty per cent. of all women have movable kidney. Several interesting papers have appeared in American journals during the past year which have added to our information with regard to this subject. Larrabee[1] gives a thorough clinical study of one hundred and twelve cases of movable kidney from the out-patient department of the Boston City Hospital. His statistics with regard to the frequency, etiology, symptoms, etc., make a valuable contribution. Treatment by operation or mechanical support was considered unnecessary in eighty-seven out of one hundred and twelve cases. Many patients were not informed of the presence of the anomaly, and when this was inadvertently done in one case symptoms promptly appeared.

Twenty-five patients were advised to wear swathes to support lax abdominal walls, the symptoms being attributed to enteroptosis rather than to the movable kidney alone. In two cases in which operation had been previously done, neither patient had been relieved. In one an unsuccessful nephropexy was followed by nephro-ureterectomy, which also failed to give relief. Larrabee did not advise surgical treatment in a single instance, and he believes that the temporary use of a bandage may tide a patient over poor health or debility until she has returned to normal health and flesh, when the symptoms usually cease.

Aaron[2] reports four hundred and forty-two cases of movable kidney treated without surgical intervention. He gives some specially valuable suggestions as to the methods of fitting supporting bandages, and believes that ninety to ninety-five per cent. of patients can be cured by a properly fitting support.

He emphasizes the importance of mapping out the position not alone of the kidney, but of the liver, stomach and other abdominal organs, which are often also displaced and in need of support. He emphasizes the indifference of many instrument makers and dealers in supporting bandages, and states that in some cases he has been obliged to have as many as five different bandages made for a single patient before a satisfactory one was obtained. Like Larrabee, he emphasizes the frequency with which enteroptosis co-exists with movable kidney, and believes that this is always the case when gastro-intestinal and nervous symptoms are present. He approves of operation only in cases of Dietel's crisis from the kinking of the ureter.

Goelet[3] takes an opposite view from these observers, and apparently believes that practically all cases of movable kidney should be operated on. He points out many reasons why the operation is frequently a failure, as well as the post-operative influences which tend in this way. Among points of importance mentioned are: Failure to detach completely the fatty capsule on the posterior surface of the kidney, which is left adherent to the colon and is thus dragged on; improper insertion of sustaining sutures or their too early removal or absorption, and attachment too low down are also men-

3. New York State Jour. of Med., 1903, vol. iii, p. 497.

tioned. Among post-operative influences causing failures he mentions vomiting or coughing after anesthesia, which loosen the attachment, turning to the opposite side, assuming an erect position or undertaking some exertion too early, neglect to adjust support for relaxed abdominal walls after operation or to correct digestive disorders. These suggestions are all of much importance in obtaining satisfactory results.

The different views of these writers may lead to confusion in the minds of some as to what course should be followed in these cases. The papers of Larrabee and Aaron emphasize an important fact which has often been brought out by other observers, the frequent co-existence of general enteroptosis with movable kidney, and that the symptoms may be as much due to the general condition as to the movability of any one special organ. Many prominent surgeons are inclined to agree with these internists that operation is not to be advised in the majority of cases. Keen has shown in how large a percentage of cases the results of operation are not satisfactory, and Morris of London, whose experience in renal surgery is probably as great as that of any living surgeon, says that when movable kidney is associated with enteroptosis, no operation should be performed. All must agree with Aaron that operation is advisable in all cases in which crises of pain occur, and we believe that by careful observation other cases can be selected in which the symptoms are chiefly caused by renal movability, and in these cases operation is, no doubt, advisable.

Valuable as are Goelet's suggestions as to the causes of failure from faulty operative technic and post-operative influences, we do not believe that failure to fix securely accounts by any means for the failure to relieve symptoms in all cases. The opinions of eminent surgeons whom we have quoted seem sound, and their failure to obtain satisfactory results certainly can not be attributed to faults connected with the operation, but are probably due to general enteroptosis; the vague discomforts caused by sagging, not only of the kidneys, but of many of the other abdominal viscera.

THE PURE FOOD AND DRUG BILL.

If there was ever a question before the national legislature in which the medical profession should be interested it is the Pure Food bill now before the United States Senate. We are sure all who read the bill, which we have already published in part and which we reproduce this week in full,[1] will at once realize its vast importance. The difference between the measure as it passed the House and the substitute reported by the Senate Committee on Manufactures is clearly defined in Senator Heyburn's letter to Dr. Reed,[1] and relates to questions of administrative detail rather than to the principles involved.

The hearings on this measure before the Senate Committee on Manufactures revealed some very interesting facts. Thus the attempt made in the bill to establish the United States Pharmacopeia as the standard of purity for drugs was combated by the proprietary medicine men with the representation that the United States Pharmacopeia was published only every ten years; that many new preparations, on which it was necessarily silent, came into use during each decennial interim and that, consequently, the United States Pharmacopeia could not be made available as a standard. This representation, naturally enough, only suggested the necessity for an additional provision, which the committee promptly framed, to protect the public from these rapidly multiplying "inventions." It was but natural, therefore, that the strictly sordid commercial interests should turn fiercely against the entire measure. The proprietary medicine trust was deeply if not vitally interested. It dropped its policy of direct representations to the committee and took recourse to its customers, the retail druggists, who, scattered all over the country, have been instigated to write letters and send telegrams to their respective senators protesting against the passage of the bill. The pressure in this instance is that of credit, which the large manufacturing concerns are in position to extend or not to their patrons, who, by counter prescribing, vend these dangerous nostrums directly to the public.

And that these nostrums, many of them at least, are dangerous in both a positive and negative sense, was also made apparent at the hearing. The testimony was direct and positive that a number of these new "inventions" were essentially poisonous, while others, innocuous so far as their ingredients were concerned, were dangerous because of their inefficiency. It was broadly stated that a number of them, by substitution of constituent elements, were frauds, a fact long and painfully known to the medical profession. The greatest danger of all, however, is the fact that the formulæ of many of these proprietary compounds are variable. As a consequence, when the Senate committee suggested that these formulæ ought to be published, or at least registered, and that it would be only fair to hold the manufacturers to their own standards, the objection was urged—the startling admission was made—that such a course would be ruinous to the large commercial interests involved. It thus becomes apparent that, in prescribing unofficial preparations physicians are very liable to be prescribing only a name with no guarantee that that name stands for anything definite either in number, quantity or quality of ingredients. Facts of this kind have long been known or at least surmised by physicians and their confidence in modern pharmacy has been almost shattered. It is true that there are many excellent pharmaceutic houses whose products have met the expectations of the profession for many years, which stand to-day on the firm foundation of well-grounded character and in which the profession has full confidence. These houses can not be injured either by this discussion or by the proposed law. They, however, owe it to themselves, at this particular crisis, to lend their best efforts in securing the passage of the pending bill, which, if enacted into law, will protect them by elevating the character of American pharmaceutic products in general. There is nothing in the proposed law to which any honest pharmacist can object. The protests of others ought to have but little weight with the Senate.

---

[1] See pages 910-911.

Beside the proprietary medicine concerns, there are the vast commercial interests involved in food adulteration and the opposition from this source and from the still more active hostility of the liquor interest working in behalf of compounded and blended drinks under various names has supported a powerful lobby ever since the beginning of the consideration of the bill.

The duty of the medical profession at this juncture is obvious. Every physician should bring his utmost influence to bear on the question. Whether he is a committeeman appointed for the purpose or not, he ought at once to write the strongest possible letter to each of his United States senators; he ought to get others, both within and without the profession, to do likewise, and especially ought he to get his druggist to co-operate. The influence of the physicians in a community on the druggist ought to be at least equal to that of the patent and proprietary medicine men. He ought to put himself in touch with the member of the National Auxiliary Congressional and Legislative Committee for his county and co-operate with him to the fullest extent. The issue is fairly joined between the proprietary medicine men and the reputable medical profession. It remains to be seen which of the two can command the most attention of the United States Senate.

THE THERAPEUTIC VALUE OF OLIVE OIL IN GASTRIC AND INTESTINAL DISEASES.

The space devoted to the therapeutic uses of olive oil in most text-books is very small, reference usually being made to the nutritive value of the oil and its use by some physicians in gallstone attacks. Rutherford[1] and his colleagues at the Army General Hospital in San Francisco have recently given an extensive trial to this medicament in cases of chronic dysentery with excellent results. Most of the cases were long-standing ones, in which the various recognized remedies for the disease had been tried over long periods of time with unsatisfactory or only partly satisfactory results. The oil was given in very large doses over long periods of time; beginning with doses of thirty cubic centimeters three times a day, the dose was gradually increased to ninety cubic centimeters three times a day. At first it was necessary to disguise the taste of the oil by mixing it with milk, but the patients soon acquired a toleration to or even a strong liking for the oil. Of the first twenty-eight completed cases under this treatment, seventeen returned to duty, and only two of these had any evidences at all of dysentery. The remainder were either discharged improved or passed from notice. Rutherford regards the results as being due in large part to the effect of the oil on the biliary secretion. The bile is increased in quantity and acts in a threefold manner; it favors the absorption of fats, stimulates peristalsis, and acts as an intestinal antiseptic. This is shown by the presence of an increased amount of bile in the feces, the cessation of signs of fermentation and putrefaction, and the general systemic improvement.

Paul Cohnheim,[2] who has been a consistent advocate of the use of olive oil in certain diseases of the stomach and duodenum, has also recently published a series of cases bearing on this subject. He advises the use of oil, particularly in cases of pyloric stenosis due to spasm of the pylorus from fissures or small ulcers. He has used it also in cases of stenosis from contracted ulcer or perigastric adhesions with a good degree of success, and even in malignant stenosis, when not too far advanced, he has found it of value. The main symptom which he regards as an indication for the use of the oil is a burning, boring pain radiating from the epigastrium upward and laterally, and occurring from two to four hours after eating. This he regards as one of the most constant symptoms of gastric ulcer or fissure. In most of his cases there were also hyperchlorhydria and definite dilatation of the stomach. The advantages of the oil are many; it relieves cramps, it lubricates the opposing surfaces of the ulcer or fissure, it reduces the hyperacidity, and it acts as a food. Cohnheim advocates the use of the oil in one large dose the first thing in the morning before food has been taken. The dose which he usually gives is from fifty to one hundred cubic centimeters. The oil is heated to the temperature of the body, and the patient lies on the right side for fifteen or twenty minutes after taking it, food being abstained from for one hour. Many patients come to like the oil, and the only unpleasant feature, a raspy feeling of the gums, may be relieved by a pinch of salt, a taste of cognac or a peppermint drop.

Rutherford advises the use of strictly pure olive oil; Cohnheim makes no mention of this, so it is fair to assume that he considers the ordinary olive oil of commerce to answer every purpose. It is probably rare that any adulterating agent is used except cotton-seed oil, of which so much is said. Many samples of alleged olive oil from Europe have been found to be mostly cotton-seed oil, which has been sent from the United States to be shipped back across the water in fancy bottles. Since it is necessary to use a good grade of the adulterant in order to pass it off as olive oil, there is little danger of its containing any injurious fatty acids or other accidental substances. The cotton-seed oil itself is similar to olive oil in effect, but some authorities think it of less therapeutic value. Since it is much cheaper than olive oil, experiments would be of value to determine its standing as a food and as a medicinal agent. For the present, however, while there is no reason for the apprehension that is felt regarding the adulteration of many foods and drugs, it seems sensible for one who is pretending to give olive oil to see to it that olive oil is really given and not cotton-seed oil.

THE PNEUMONIA DEATH-RATE.

The changeable weather of these last few weeks after the severe winter has caused a lowering of resistive vitality in practically all weakened individuals, which has been followed by an alarming increase in the number of deaths from pneumonia in nearly every city in the country. There seems no doubt that the disease is much more prevalent and even more fatal than it has been any time during the past decade, at least. At the same time there is no question that pneumonia is now recognized much more surely than was the case even ten or fifteen years ago. This is especially true as regards children. And it must not be forgotten that a large proportion of the present death-rate from pneumonia is due to deaths of those under five years of age. In the olden times a child died from measles or whooping cough that now dies from bronchopneumonia, complicating measles or whooping cough. The same thing is true for other infectious diseases of childhood. Among adults, too, there is no doubt that in many cases, especially among the old, death was attributed to an affection of the heart or to a complication of diseases or to the nephritis that is so often the underlying reason for the lowered resistive vitality on the basis of which the pneumonia develops rather than to the terminal pneumonia which now figures so prominently in these statistics.

We would not wish to discourage in any way the laudable efforts of boards of health to decrease if possible the death-rate from pneumonia, but we cordially deprecate the present scare-headlines in newspapers, which have proved so disheartening to so many patients who would otherwise have had the courage to face their pneumonia without undue shrinking. Everyone knows how important, in diseases of the lungs particularly, is tranquillity of the patient's mind. Under present circumstances it is very difficult to secure this. In many cases no amount of reassurance by the physician will undo the lamentable effect of the discouragement produced by pessimistic newspaper discussions of pneumonia.

Even at the present time, it must not be forgotten that pneumonia is of itself not an especially fatal disease. As has been very well said, the prognosis of pneumonia in patients who are over fifteen and under fifty depends very much on what constitutional dyscrasias the patient labors under when the pneumonia attacks him. f there is an affection of the heart the patient is almost ably doomed. If there is an affection of the kid- atters not what treatment be employed, it will only be by the most fortunate chance that the patient will survive. If the patient has had an affection of the lungs, the pneumonia may be recovered from, but it is almost inevitable that the patient will have subsequent exacerbations of the previously existing pulmonary trouble. It is these three complicating factors that make pneumonia so serious a malady, and not the pulmonary affection itself in spite of all the talk about it.

It is well understood that patients suffering from heart or lung or kidney affections, do not stand continued cold well. As a result of this, we have many more in our population with lowered resistive vitality this spring than has been the case for over a quarter of a century before. It is this that has caused the increased mortality of pneumonia. Doubtless in many of the large cities influenza prevails, and the depressing effect of this disease makes the prognosis of pneumonia especially unfavorable.

There are certain other factors at work which serve to explain and minimize the appalling notion that might be gathered from pneumonia statistics, and these in the present state of the public mind should, it seems, be emphasized.

Many of our people have grown accustomed to taking depressant drugs of various kinds for the slightest pain or ache, and these have undoubtedly had an effect, especially on sufferers from heart and kidney disease. If the increase of advertisements can be considered as evidence—and students of the psychology of advertising are quite ready to think so—then stimulants are being used more commonly in this country than before. This does not mean necessarily to excess, but the moderate, regular drinker is much less likely to recover from pneumonia than the man who has never been accustomed to take spiritous liquors except for special reasons at longer intervals.

It would seem advisable at the present moment for physicians to keep many of these considerations before the public in order to prevent the evil effects of too much scare-head sensationalism with regard to pneumonia fatality. Patients whose resistive vitality is distinctly lowered by the severe winter just passed must be warned of the dangers they incur in crowded cars, department stores, depots, theaters and the like, and must also be warned not to neglect the first symptoms of the disease. and especially not to consider that a chill is due only to a cold and that they will probably shake it off.

SANITATION AND THE PANAMA CANAL.

The efforts to secure a member of the medical profession on the Isthmian Canal Commission, while in one sense resulting in failure, were not entirely lost. The letters and telegrams which poured into the executive mansion asking for the appointment of Major Gorgas, reached the President too late to secure all that was asked, but recent developments show that the President was influenced by them. In the letter of instructions to the Isthmian Canal Commission the President specifically mentioned only one thing, and that was the sanitary arrangements. In his letter he said:

> There is one matter to which I wish to ask your special attention, the question of sanitation and hygiene. You will take measures to secure the best medical experts for this purpose whom you can obtain, and you will, of course, make the contractors submit as implicitly as your own employes to all the rules and regulations of the medical department under you. I presume you will find it best to have one head for this medical department, but that I shall leave to your own judgment.

We understand that Major Gorgas will be given charge of the sanitary arrangements, although no definite action regarding the matter has been taken.

GLYCERINATED VACCINE LYMPH.

Nothwithstanding the widespread use of glycerinated lymph in the last few years there are certain fundamental facts regarding it which as yet have not been thoroughly grasped by the profession at large. We refer particularly to the different effects produced by vaccine lymphs of different ages. These points are of great practical importance, and have recently been emphasized anew by Levy.[1] As this author states, the glycerin was originally added to the lymph with the idea that it caused a rapid loss of virulence in the pus cocci which are almost always present in the lymph, without materially affecting the activity of the vaccine organism. As Levy points out, the latter organism is also weakened in activity by the glycerin, and much more rapidly than was at first supposed. Levy compares the effect of fresh and old lymph on revaccinated cases, and on original vaccinations. His main conclusions are that in original vaccinations the lymph used should always be at least four weeks old, since lymph of this age rarely causes the severe inflammatory reaction seen after the use of fresh lymph. On the other hand, fresh lymph should always be used in revaccinations, as old lymph often fails to produce any reaction in cases which are susceptible to vaccinia, but only when a strong lymph is used.

THE CONTAGION OF SCARLET FEVER.

In this issue of The Journal we abstract an article from the *Lancet* by Dr. Lauder, who expresses the opinion—not a new one—that the contagion of scarlet fever is conveyed by the respiratory tract, and that the constitutional condition and rash are only the results of toxic products and not dangerous as regards the spread of the disease. This is an opinion quite contrary to the one ordinarily received, but his experience reported in the article referred to in the management of scarlet fever would seem to indicate its correctness. The germ of scarlet fever is one that is unknown to us, and, therefore, our knowledge of the disease is to that extent limited, but a careful clinical study will enable us to do much to check the ravages of even an unknown germ. The capriciousness of the contagion of scarlet fever has been observed by almost every practitioner, and it may perhaps be explained by the observers' assumption that the contagion was conveyed in the rash and its products. A closer study of the cases with a view as to the dangers of respiratory matter and the conditions of the throat and nose will perhaps make this capriciousness in scarlet fever less mysterious. As in diphtheria, it is possible that the greatest danger is in the intimate contact with the patient, and that the infection itself is sometimes comparatively short lived. This, however, is a matter for further study.

THE DIAGNOSTIC VALUE OF EOSINOPHILES IN THE SPUTUM.

Since their discovery by Wharton Jones, the coarsely granular leucocytes, now known as eosinophiles, have attracted a good deal of attention. In recent years their increase in the blood in certain diseases, and particularly in diseases caused by intestinal parasites, has led to renewed activity in their investigation. The increase of these cells in the sputum in asthma, and their relation to the Charcot-Leyden crystals, have been repeatedly discussed. In diseases of the lung, other than asthma, various observers also have described either an increase or a lack of eosinophiles. In general, there has been an agreement among these authors that the eosinophiles are increased in asthma and bronchitis and decreased in tuberculosis, so that in cases of suspected tuberculosis, in which tubercle bacilli could not be found, an absence of eosinophiles from the sputum was thought to favor a diagnosis of tuberculosis. Some writers have, however, persistently asserted that eosinophiles were present in tubercular as well as in asthmatic and in bronchitic sputum. In a recent article, Hildebrandt[1] gives his results of studies on this question. The sputum was obtained from cases of various forms of tuberculosis—cases with acute and chronic bronchitis, bronchial asthma, pneumonia and lung infarcts. The conclusion at which the author arrived was that eosinophiles in the sputum were a rule rather than an exception; that they were not a diagnostic sign of bronchial asthma, and that they were present in pulmonary tuberculosis. In view of the recent comparative work of Opie,[2] who demonstrated the frequency with which eosinophiles are found in the respiratory tract, and also noted their extrusion into the lumen of the bronchi, their presence in the sputum might be expected frequently. A careful histologic study of human lungs in normal and pathologic conditions to determine the frequency of eosinophiles in the air passages, and the conditions which influence their migration, seems indicated.

CANINE MALARIA.

Experiments on animals are undoubtedly of the greatest value in settling special questions, but there is a large field of clinical observation in more general lines that is equally valuable in medicine. The comparative pathology of diseases is a study which has not received as much attention as it really deserves. Especially is this the case with our domestic animals, whose close association with the human species renders their disorders of special interest and often of serious importance to their masters. Dr. A. B. Dalgetty of South Sylhet, India, reports[3] the case of a fox terrier which seemed out of sorts with a certain periodicity of symptoms and with hematuria; these facts led him to investigate the blood, and he found a large number of parasites very closely resembling the malarial germ. The ring-shaped appearance recalled the parasite of malignant malaria. There was intense anemia, and an examination of the blood-colored urine revealed no red corpuscles, showing that the color must have been due to the hemoglobin alone, and that the destruction of the blood cells was very great. The therapeutic test bore out the diagnosis. Quinin in two- to three-grain doses was given daily for some time, and the immediate improvement showed that the disease was of malarial nature. As soon, however, as quinin was discontinued the old symptoms recurred, though in a milder form. Considering that the disease was due to the malarial parasite, Dalgetty asks whether it might not be fairly established that the dog is a possible source of infection to man, perhaps carrying malaria into sections where it may not have existed. We have not before seen an account of such a case in a dog so closely resembling the malignant malaria with its accompanying hemoglobinuria. It is not mentioned by either Scheube or Manson. The diseases of our domestic pets are very much neglected, and their involuntary revenge may be expensive and inconvenient. The subject is one that is worth further study; in fact, the subject of diseases in the lower animals deserves a pretty thorough elucidation as a matter of human self-defense.

THE RELATIONS BETWEEN MEAT POISONING AND PARATYPHOID FEVER.

According to the investigations of Trautmann,[1] there appears to be an intimate and interesting relationship between the bacilli regarded as the cause of certain meat poisonings and paratyphoid bacilli. Both Trautmann, Schottmüller and B. Fischer, as well as de Nobele, regard all these organisms as belonging to the same group. Hitherto we have thought of paratyphoid bacilli only in connection with a rather mild kind of typhoid-like disease, and at first sight it seems somewhat far-fetched to attempt to place meat poisoning and paratyphoid under the same etiology. It may be pointed out, however, that while these bacilli are closely related, yet there are minor differences on part of the various races, and that differences in the clinical manifestations of the infections might be accounted for on the score of biologic differences in the organisms. The virulence of the bacilli and susceptibility of the patient are also highly important factors that should not be left out of sight. Trautmann, in considering this question, would put special stress on the difference in the conditions under which the infection takes place in meat poisoning and ordinary paratyphoid fever. In the case of poisoning, meat (improperly prepared, uncooked?) of infected animals is taken into the stomach. meat that often contains not only the bacilli perhaps, but also the toxic products of the latter. This is followed by acute and violent symptoms, e. g., vomiting and diarrhea, ending in early death, or recovery after, perhaps, protracted illness. In case of ordinary paratyphoid fever, the infection is established with a relatively much greater slowness, and the symptoms become apparent much more gradually. Trautmann observed, furthermore, that in the epidemics of meat poisoning there occurred certain cases that form transitions between the two types of infection, and he consequently regards typical meat poisoning as a hyperacute and paratyphoid as a subacute form of the same infectious disease. If this view is adopted generally, the pathogenic importance of paratyphoid bacilli will be increased greatly. In order to secure additional information in regard to these questions, all cases of meat poisoning should be studied with the greatest care from the bacteriologic point of view. It appears that in Germany epidemics of meat poisoning have followed the consumption of more or less improperly prepared meat of infected animals, and Trautmann suggests that in cattle paratyphoid organisms cause an epizootic after the nature of anthrax. This in itself is an interesting question in comparative pathology.

Medical News.

ILLINOIS.

Promotional Examination.—A promotional examination for senior physicians at Cook County Institutions, Dunning, will be held, April 14, 15 and 16.

Medicine Men Jailed.—"Drs." Wallace and Miller, itinerant medicine men who victimized Tazewell County farmers, were fined at Pekin, March 14, and in default of payment were committed to jail.

Golden Anniversaries.—Dr. and Mrs. William E. Gilliland, Coatsburg, celebrated their golden wedding, March 22.——McLean County Medical Society will celebrate its semi-centennial at Bloomington with a banquet, April 7, at which Dr. Franklin C. Vandervort, president, will be toastmaster.

Consulting Staff at Dunning.—The county board has confirmed the following appointments to the consulting staff of Cook County Institutions, Dunning: Internal medicine, Dr. Frank Billings; surgery, Dr. John B. Murphy; pathology, Dr. William A. Evans; insanity, Dr. Hugh T. Patrick, and tuberculosis, Dr. Arnold C. Klebs, all of Chicago.

Smallpox.—The appearance of two or three cases of smallpox at the Cottage Hospital, Peoria, has necessitated temporary closure of the institution, and quarantine.——Carlyle has six cases.——Seneca and Marseilles have discovered that the supposed chicken-pox which is prevalent there is smallpox.——Streator reports the smallpox epidemic at an end. There were 44 cases and two deaths.

Personal.—Dr. Henry C. Fairbrother, East St. Louis, was appointed by the governor, on March 28, a member of the Illinois State Board of Commissioners of Public Charities. The other medical member of the board is Dr. William Jayne of Springfield.——Dr. A. B. Middleton, Chatsworth, is seriously ill with pneumonia.——Dr. John E. Covey, Lexington, sailed for London March 22.——Dr. William P. Schirding, Palatine, returned from Vienna a few days ago.——Dr. John W. Colbert, Jacksonville, has been appointed physician of a Presbyterian hospital in Puerto Rico.

Chicago.

Still Sporadically Enforced.—Four individuals charged with violating the anti-spitting ordinance, were fined each $1 and costs, March 28.

Physician Exonerated.—Dr. Bruce T. Bowens, charged with having performed an operation which resulted in the death of Mrs. Minomi Chandler, was exonerated by the coroner's jury.

Again Pneumonia Leads.—During the week ended March 26, 156 of the 626 deaths reported, or 24.92 per cent., were due to pneumonia. Consumption caused 76 deaths, heart diseases, 50; Bright's disease, 42, and violence 36. The mortality shows an annual rate of 16.32 per 1,000.

---

[1] Zeitschr. f. Hyg. u. Infectionskr., 1903, xlv, 139; and 1904, xlvi, 68.

University and Bellevue Alumni to Meet.—The fourth annual meeting and dinner of the Western Alumni Association of the University and Bellevue Hospital Medical College will be held at the Sherman House April 11. Professors Joseph D. Bryant and Egbert Le Fevre of New York will be the guests of the evening. Dr. David W. Graham, Chicago, is president of the association, and Dr. Willis O. Nance, 100 State Street, Chicago, is the secretary. Former students of Bellevue or of the University who have not received invitations to the meeting may do so by addressing the secretary.

Boil the Water.—The Department of Health announce that there will undoubtedly be an increase of typhoid fever and the acute intestinal diseases among those who drink untreated hydrant water. There had previously been noted an increase of the colon group of bacilli from a previous 35.7 per cent. to 56.5 per cent. of the examinations. This fortnight's increase is already reflected in the increased deaths from the acute intestinal diseases—from 14 during the week of March 19 to 31 during the week of March 26, or more than 120 per cent. Such an increase is a sure precursor of an increase of typhoid fever.

Warning Against Rabies.—The number of rabid dogs which have been killed during the last few weeks, brings from the department of Health the advice that the public should appreciate the importance of securing a dog that has bitten anyone and keeping him alive until it is positively known whether or not he is suffering from rabies. It also recapitulates the symptoms of rabies in dogs as follows:

> Beware of a dog when it becomes dull and hides away; appears restless; always on the move and prowling; whose countenance is somber and sullen; walks with head down like a bear. Beware of one that barks at nothing, when all around is still. Beware of a dog that scrapes incessantly and tears up things. Look out for the dog which has become too fond of you and is continually trying to lick your hands and face. Beware, above all, of the dog which has difficulty in swallowing, which appears to have a bone in its throat, and one that has wandered from home and returns covered with dirt, exhausted and miserable.

INDIANA.

Smallpox.—During February 408 cases of smallpox were reported, with 5 deaths, from 34 counties. In the preceding month there were 480 cases and 8 deaths in 38 counties, and in the corresponding month of 1903 there were 889 cases, with 50 deaths in 59 counties.

Physicians Injured.—Dr. William H. Kluge, Indianapolis, sustained injuries to his spine by being thrown violently against a car platform by a lurch of the car.——Dr. Cortez M. Leeth, West Indianapolis, was beaten with knuckles in an attempted hold-up and rendered unconscious.

Prevalent Diseases.—Measles was the most prevalent disease in February; then follow, in the order given, bronchitis, pneumonia, influenza, tonsillitis, rheumatism, scarlet fever, typhoid fever, diphtheria, diarrheal diseases, erysipelas, whooping cough, cerebrospinal meningitis, dysentery, puerperal fever, cholera morbus and cholera infantum.

Registering Phthisis.—The State Board of Health has issued blanks to local health boards for complete reports of cases of tuberculosis. This follows the order requiring physicians to report all such cases, as other contagious or infectious diseases are reported. It is expected, from these reports, and those of inspectors, to have a complete history of each case.

Increase in Pneumonia.—The increase in pneumonia is alarming, the total deaths in Indiana in February being almost twice as many as from tuberculosis. The pneumonia death rate in the cities is 417 per 100,000, and in the country 323. Of the total pneumonia deaths 353 were females and 429 males, and 155 were children under one year of age. A careful study of the matter points to the conclusion that the pneumonia increase attended the increase in measles and influenza, and was not caused by weather conditions.

February Deaths.—The total number of deaths in February was 3,477, equivalent to an annual rate of 17.4 per 1,000. In the corresponding month last year the deaths numbered 2,677, or 13.8 per 1,000. In January there were 3,177 deaths, a rate of 14.8 per 1,000. The increase in pneumonia is responsible in a degree for this increase in deaths. Some important causes of death were: pulmonary tuberculosis, 365; typhoid fever, 60; diphtheria, 32; scarlet fever, 23; pneumonia, 711; influenza, 116; cancer, 78; violence, 142, and smallpox, 5. The city death rate was 21.7, and the country rate 15.1. The cities present the highest death rates in consumption, typhoid fever and pneumonia. The country presents a higher death rate in influenza. Two of the smallpox deaths occurred in cities, and three in the country.

Personal.—Dr. David G. Linville, Columbia City, has entered on his eighty-third year.——Dr. Horace Wardner, superintendent of the Home Health Club Hospital and Sanitarium, La Porte, has resigned on account of ill health, and has been succeeded by Dr. Hulbert Fuller of Chicago.——Dr. and Mrs. John W. Younge, Fort Wayne, sailed, March 8, on a trip to the Mediterranean and the Holy Land.——Dr. William Cluthe, Tell City, has been appointed secretary of the Perry County Board of Health, vice Dr. James B. Bennett, Derby.——Dr. David S. Stanton, Portland, secretary of the local board of health, 82 years of age, is said to be the oldest health officer in Indiana.——Dr. Stanley W. Edwins, Elwood, has given up practice, on account of ill health.——Dr. S. F. Kincaid, Taylorsville, has been appointed health officer of Bartholomew County.——Dr. Homer C. Stalker, Salem, has succeeded Dr. Theodore C. Sargent, Lafayette, as chief of the medical staff of the Indiana State Soldiers' Home, Lafayette.——Dr. J. Edwin Showalter has been made secretary of the Waterloo Board of Health, vice Dr. Frank Broughton, resigned.

IOWA.

Drugless Healers Exempt.—Judge J. H. Richards, Webster City, has ruled, in the case of the State of Iowa against "Dr." J. Wilson, Edmunds, for alleged illegal practice of medicine, that "drugless healers" do not come under the provisions of the medical practice act.

Typhoid Germs in Cedar River.—Drs. Henry Albert and Walter L. Bierring, to whom was entrusted the task of determining the source of typhoid fever infection in Waterloo, have demonstrated that the typhoid germs came not from infected wells, but from the Cedar River, the source of the water supply of the city.

State Hospitals.—The senate has voted an appropriation of $125,000 for the establishment of a state hospital for inebriates at Knoxville. The former industrial home for the blind will be used, and new buildings erected. The bill provides that treatment is not to exceed three years.——The home committee on appropriations has passed a bill devoting $50,000 to the erection of a state hospital for consumptives.

Personal.—Dr. John G. Mueller, Iowa City, has been appointed examining surgeon of the university battalion, vice Dr. J. W. Harriman, deceased.——Dr. August Anderson, Sioux City, who was seriously injured in an acetelene gas explosion, February 29, is making a satisfactory recovery.——Dr. Lee W. Dean, Iowa City, professor of otology, laryngology and rhinology in the University of Iowa, has been granted indefinite leave of absence on account of ill health.——Dr. William L. Miller is critically ill at his home in Des Moines.

LOUISIANA.

Commencement.—Flint Medical College, New Orleans, held its fifteenth annual commencement exercises, March 11, graduating a class of five. The annual address was delivered by J. Madison Vance, and Dr. F. H. Knight presented the diplomas.

War Against Mosquitoes.—The State Board of Health has transmitted copies of resolutions adopted March 1, to all physicians in the state, emphatically urging them "and all other persons attending patients with fever to carefully keep a well-tucked bar over such patients, especially during the first four days of their illness, and as far as practicable to destroy mosquitoes about the patient's bed and room. This precaution should be particularly observed from April 1 to November 30."

Personal—Dr. T. A. Jones has been elected secretary of the faculty of Flint Medical College of New Orleans University, vice Dr. A. J. Lopez, resigned to accept the chair of neurology.——Dr. Clarence L. Horton, New Orleans, medical inspector of the State Board of Health, has withdrawn from the service on account of his removal from the city.——Dr. Holt King, Baton Rouge, has been appointed medical examiner for Louisiana at Ceiba, Spanish Honduras, and Dr. J. S. Aliston, Natchitoches, medical examiner at Belize.——Dr. Lester J. Williams, Baton Rouge, has been appointed marine medical inspector on ships plying between New Orleans and Central America.——Dr. Harvey J. Clements, New Orleans, is taking a vacation of five months.

MAINE.

Smallpox.—Calais has several cases of smallpox, and St. Stephen is enforcing a strict quarantine and vaccination.

"Holy Ghosters" in Trouble.—Rev. T. W. Sanford, leader of the "Holy Ghost and Us" Society in Auburn, was found guilty of cruelty in compelling his little son, aged 6, to fast 72 hours. Trial on a charge of manslaughter because he refused to allow a physician to be called to another boy, 14 years old, who later died of diphtheria, resulted in a disagreement of the jury.

Society's Semi-Centennial.—The Penobscot County Medical Association celebrated the conclusion of the first half century of its existence by a banquet at Bangor, February 22, at which about 75 were present. President Dr. Daniel McCann called the meeting to order and designated Dr. Augustus C. Hamlin as toastmaster. Dr. Daniel A. Robinson reviewed the history of the organization; Dr. George A. Phillips, Bar Harbor, read an original poem, and Dr. Augustus S. Thayer, Portland, president of the Maine Medical Association, made a plea in favor of organization.

MARYLAND.

Refuse Appropriation to Colleges.—The legislature has decided not to grant the appropriation of $4,000 asked for by each of the medical colleges of Baltimore.

No Library Building.—The medical and chirurgical faculty failed to get any appropriation for its library building from the legislature. It is probable the application will be renewed two years hence.

Baltimore Deaths.—Two hundred and thirty-six deaths were reported last week against 200 last year, being an annual death rate of 22.10 per 1,000; white 18.77, colored 40.24. The principal causes of death were pneumonia, 46; consumption, 36; Bright's disease, 13; cancer, 11; bronchitis, 10; influenza, 8; scarlet fever, 5; and typhoid fever, 3.

Appropriation Bills for Hospitals.—Bills are before the legislature for appropriations of $200,000 to complete Springfield State Hospital for the Insane; $66,000 for the Maryland Asylum and Training School for the Feeble-minded, $53,000 to complete buildings at Maryland Hospital for the Insane, and $10,000 for the Cambridge Hospital. The omnibus appropriation bill, recommended by the ways and means committee, and introduced into the house, provides the following annual appropriations: Maternity of College of Physicians and Surgeons, $3,000; Nursery and Child's Hospital, $2,500; Hebrew Hospital, $4,000; Home for Incurables, $2,500; Hospital for the Women of Maryland, $4,000; Baltimore City Hospital, $7,000; Maryland General Hospital, $5,000; University Hospital, $5,000; Maryland Lying-In Hospital, $3,000; St. Joseph's Hospital, $5,000; Franklin Square Hospital, $2,500; Union Protestant Infirmary, $5,000 (the last seven on condition of taking a certain number each of state patients); St. Agnes Hospital, $3,500; Hospital for Relief of Crippled and Deformed Children, $5,000; Provident Hospital (colored), $1,500; Hospital for Consumptives, $5,000; Baltimore Eye, Ear and Throat Hospital, $2,000; Southern Dispensary, $500; Johns Hopkins Hospital, $20,000; Home and Infirmary of Western Maryland at Cumberland, $7,500; Peninsula General Hospital, Salisbury, $5,000; United Charities Hospital, Dorchester County, $6,000; Johns Hopkins University, $25,000; Frederick City Hospital, $3,500; Northeastern Dispensary, $1,000; Emergency Hospital, Annapolis, $2,500; Washington County Hospital, Hagerstown, $6,000; Silver Cross Home for Epileptics, Port Deposit, $1,500, and West End Maternity, $1,000. The annual appropriations are for two years, or until the next legislature meets. The omnibus bill being introduced is equivalent to the above appropriations being actually made.

MASSACHUSETTS.

Mulcted for Unauthorized Autopsy.—The courts have decided that permission for an autopsy on his child was not granted by Louis Bromberger, and that the Massachusetts General Hospital must pay him $50. Suit for $2,000 was brought.

Additions to Asylums.—The Massachusetts senate will appropriate about $300,000 to be used for new buildings and improvements at the Westboro Insane Hospital, the Taunton Insane Hospital and the School for Feeble-Minded Children.

Hospitals Benefit.—The Salem City Hospital benefits as residuary legatee of Miss Hannah K. Grant of that city, her sister having the use of the property during life. The fair held at the Hotel Vendome, March 26 and 27, netted nearly $5,000 for the Infants Hospital, Boston.

Golden Wedding.—Dr. and Mrs. Joshua Bailey Gould of Somerville, Mass., celebrated their golden wedding, March 23. Dr. Gould is nearly 85 years old, and after practicing medicine in Templeton and adjoining towns came to West Somerville in 1874, and continued practice there till his eightieth birthday, a period of active practice of over 50 years.

Surgeon General Resigns.—Brigadier-General Robert A. Blood, Charlestown, surgeon general of the Massachusetts Volunteer Militia, has resigned, to take effect May 2. It is expected that Lieutenant-Colonel Otis H. Marion, Brighton, will succeed him. Dr. Marion joined the First Regiment in 1883, becoming medical director of the First Brigade in 1897. This position he has since held, except for a year, 1898, when he went to the front with the Sixth Infantry

Personal.—Dr. Harold Williams, dean of Tufts Medical School, who with his family has spent the winter in France is expected home in May.——Among Boston physicians who will spend Easter at Washington, Baltimore or Philadelphia are Drs. Dudley Williams, Whitredge Williams, John P. Reynolds, Moses Douglass, and Henry Barton Jacobs.——Dr. Arthur E Austin, professor of medical chemistry and toxicology in Tufts Medical School, is studying in Ludwig's bio-chemical laboratory, Vienna.

MINNESOTA.

Epidemics in Minneapolis.—It is reported that there are more than 200 cases of typhoid fever in Minneapolis, and that the number is steadily increasing. At least 14 deaths from this cause occurred during February.——During the week ended March 21 17 new cases of smallpox were reported in the city, a number of which were in Augsberg Seminary.

Personal.—Dr. Frederick A. Dunsmoor has resigned as medical director of Asbury Hospital, Minneapolis, and Dr. J. Warren Little has been appointed to succeed him.——Dr. Jacob E. Schadle, St. Paul, has been appointed professor of rhinology and laryngology in the College of Medicine and Surgery of the University of Minnesota, Minneapolis, to succeed Dr. Winfield S. Laton, Minneapolis, resigned.

Would Avoid Notoriety.—The Brown and Redwood County Medical Society, at its last meeting, put on record the desire of its members to avoid newspaper notoriety by passing the following resolutions:

> *Resolved*, That the secretary be authorized to request editors not to mention the name of any physician in connection with any case, and be it further
>
> *Resolved*, That a copy of this resolution be sent to all newspapers in Brown and Redwood counties.

Must Report Births and Deaths.—A circular has been sent to physicians and county officials calling their attention to the law requiring parents and householders to notify the county clerk or health officer of all births and deaths of members of their households under penalty of a fine varying from $5 to $25, and requiring physicians to report within ten days all births and deaths, and midwives to report all births under a penalty of fine or imprisonment.

NEW YORK.

Getting in Line.—Orange, Richmond and Essex county medical societies have ratified the union of the state medical society and association.

Albion's Water Supply Impure.—In a report to the State Department of Health Professor Olin Landreth says the Albion Water Company is supplying canal water to the village, and that the water is a menace to health, and that its use must be discontinued.

Object to Use of Summer Resort for Insane.—People living along the Great South Bay have presented a petition to the state lunacy board begging it to alter its intention of accommodating the mildly insane at the Surf Hotel on Fire Island, as it would greatly interfere with their profits during the summer, which are derived from conveying parties to this island on picnics and excursions.

New Bills.—There is a bill now before the legislature to prohibit the use of cocain.——Mr. Platt has also introduced a bill requiring that the formulæ must be printed on the wrappers of patent medicines.——Mr. Nye's bill to regulate the practice of optometry also had a hearing.——Senator Hawkins has introduced a remarkable bill regulating the practice of osteopathy. It provides that the board of regents shall conduct examinations for those qualified to practice. The exemptions are precisely the same as those made in the Wilcox bill for optometry. In a slightly different form this measure has been introduced into several legislatures, but has never emerged from committee.

State Lunacy Commission Bill.—The senate finance committee reported favorably on Senator Malby's bill empowering the commissioner in lunacy to enter into an amicable arrangement with the emigration authorities of the government, by which a more careful inspection may be made as to the mental condition of immigrants landing at the port of New York. On the completion of such an arrangement the state commission is authorized to appoint a board of alienists for the examination of insane, idiotic, imbecile and epileptic immigrants, to consist of a chief examiner at a salary of $5,000, and two assistants at a salary of $3,000 each. The commission in lunacy believe that there is no more serious economic question confronting taxpayers to-day than that pertaining to the immense flood of immigration. Of the aliens landing at Ellis Island, 44 per cent. give New York City as their prospective permanent home, therefore it can be seen that the usual percentage of defectives among this class will become a permanent burden on the state. At the present time there are admitted each week to the Insane Retention Pavilion of Bellevue Hospital, at least 4 recently landed immigrants who show marked evidences of mental derangements.

Buffalo.

Personal.—Dr. Roswell Park left for Berlin to attend the annual meeting of the German Surgical Society. From Berlin he will visit Mikulicz at Breslau and MacEwan at Glasgow. ——Dr. David E. Wheeler has been appointed visiting genitourinary surgeon at the Sister's Hospital.

New York City.

Vital Statistics for 1903.—Health Commissioner Darlington reported for the year 1903 that there were 67,864 deaths, 94,755 births, and 31,174 marriages. Pneumonia caused 9,174 deaths; tuberculosis, 9,403; Bright's disease, 5,636, and violence, 4,068. There were 805 suicides.

Instruction in First Aid.—The board of education has arranged for the delivery of a series of free lectures to be given in the boroughs of Manhattan, Brooklyn and Queens. Those who have taken the course and passed a satisfactory examination will be entitled to a certificate and may wear the first-aid insignia.

City Hospitals Overcrowded.—The records of the twenty largest hospitals in the city, taken March 26, show that there are only 56 vacant beds in hospitals, with an aggregate capacity of 5,446. Were it not for the recent opening of the new Mount Sinai Hospital, the accommodations would be totally inadequate to the number of patients.

Personal.—Dr. Rudolf Rapp has been appointed to the staff of the Craig Colony for Epileptics at Sonyea, N. Y.——Dr. Hermann M. Biggs recently presented the exhibit prepared by the New York Board of Health for the St. Louis Exposition, at the Academy of Medicine.——Dr. William T. Bull has practically recovered from his recent illness.

County Society Election.—At the meeting March 21, the following officers were elected: President, Dr. Francis J. Quinlan; vice-presidents, Drs. Henry A. Dodin, and S. Busby Allen; secretary, Dr. William R. Stone; corresponding secretary, Dr. John J. Nutt; treasurer, Dr. Charles E. Denison; executive committee for three years, Dr. Alexander Lambert; for two years, Dr. Frederick W. Loughran. Sixty fellows and sixty alternates were also appointed for the state association.

Jamaica Hospitals Fight.—The differences between the Jamaica and St. Mary's hospitals of Jamaica, Long Island, over the proposed redistribution of the districts of the two hospitals are about to be investigated. At present the Jamaica Hospital receives calls from all points south of Fulton Street, Jamaica, which gives it the railroad cases, and against this St. Mary's Hospital protests. It is charged against the Jamaica Hospital that the orderlies have been sent out on ambulance calls to act as physicians.

Loomis Laboratory vs. New York University.—When the amalgamation was made between the New York University (medical department) and Bellevue Hospital Medical College the Loomis laboratory went with the amalgamation. The university trustees sought to impress a trust on the laboratory property, asserting that the laboratory was a part of the university itself. In the Supreme Court, Justice Truax has decided that the university is not entitled to a reconveyance of the property, and this decision has been upheld by the Appellate Division, whose judgment is now affirmed by the Court of Appeals.

OHIO.

Typhoid Decreasing.—In the week ended March 19, only 19 deaths from typhoid fever occurred in Cleveland, and 54 new cases were reported.

Physicians Want Representation.—On March 28 a resolution was passed by the Academy of Medicine, Cincinnati, requesting the mayor to appoint a member of the medical profession to fill the vacancy on the health board. At present the board is composed of six members, not one of whom is a physician.

Personal.—Dr. Walter W. Brand, health officer of Toledo, has been given an increase in salary from $1,800 to $2,800 a year. ——Dr. Andrew C. Kemper, Cincinnati, has been admitted to the Soldier's Home, Dayton.——Dr. Joseph A. Murphy, Columbus, has been appointed coroner of Franklin County, vice Dr. Oliver W. Lindsay, deceased.

Hospital Loses by Technicality.—By the will of Benjamin Wood Davis, the Jewish Hospital, Cincinnati, is bequeathed $10,000. Unfortunately the will was made less than one year ago, and therefore this bequest is void under the statutory provision which requires that a will must have been made more than a year before death to make such bequests valid.

Academy Election.—The election of officers of the Cincinnati Academy of Medicine, held March 7, resulted as follows: President, Dr. Simon P. Kramer; vice-presidents, Drs. John M. Withrow and Julia W. Carpenter; secretary, Dr. Stephen E. Cone; treasurer, Dr. M. Agnus A. Tate; librarian, Dr. Arch. I. Carson; trustees, Drs. E. Gustav Zinke, James F. Heady, and David I. Wolfstein; delegates to the state medical association, Drs. Charles A. L. Reed, Simon P. Kramer, Louis Schwab, and Mark A. Brown, and alternates, Drs. Charles L. Bonifield, Louis Stricker, David I. Wolfstein and George A. Fackler.

PENNSYLVANIA.

Physicians' Injuries.—Dr. F. Otis Bryant, Chester, while returning from a call in his carriage, was struck by a trolley car and severely injured, but not fatally.——Dr. George I. McLeod, Ardmore, whose feet were run over by a railroad train last December, sustaining injuries which necessitated double amputation, is now able to be about on artificial feet.——Dr. William H. Warder, one of the oldest practitioners of Philadelphia, was severely injured by being thrown from his carriage, March 23.

Reorganization.—The State Board of Health will issue a circular letter to the various medical societies throughout the state, asking them to aid in obtaining legislation to reorganize the system of health reports. Dr. Lee, the secretary, will suggest that the various medical societies throughout the state adopt resolutions urging on senators and representatives the importance of enacting laws to establish a health officer in every county, and a deputy health officer in every township. These representatives shall be directly responsible to the State Board of Health. All incurable diseases are to be reported both by physicians and householders, and he further suggests that all water companies be placed under state supervision.

Insane Asylum Condemned.—Investigations by the grand jury and representatives of the state lunacy board reveal that the present buildings of the Schuylkill County Insane Asylum are entirely overcrowded and unfit for occupancy, and that the sanitary conditions are of the most ancient description. There are 250 insane patients to be cared for by Schuylkill County, and 149 of these are being treated in the state institution in Danville. Dr. George I. McLeod, president of the state lunacy board, says that much better results could be obtained if the "County Care Act" were taken advantage of. By this act the county insane asylum would come under state control, and at the same time receive from the state $1.50 per week for each patient. In order to secure this state aid the county must provide suitable buildings.

Philadelphia.

Bequests.—By the will of Albert J. Cliff there will revert at the expiration of trust the residue of $45,000 to the Methodist Episcopal Home for the Aged and Methodist Hospital, share and share alike.——By the will of Mary P. Wernwag the sum of $60,000 is devised in trust for the benefit of the Home of the Merciful Saviour for Crippled Children.

Banquet to Dr. Shoemaker.—On March 22 Dr. John V. Shoemaker, professor of therapeutics in the Medico-Chirurgical College, was entertained by the faculty of the college in celebration of the thirtieth anniversary of his entrance into medical practice. Dr. Shoemaker was presented with a silver shield containing the seal of the college and the names of his associates in the faculty.

Philadelphia Hospital Examinations Deferred.—As a result of an interview by the dean of the different medical colleges with Mayor Weaver, regarding the date of the examinations for internes, the examinations will be held on or about May 10, instead of a month earlier, as was first announced. This arrangement is made in order not to conflict with the student examinations in the colleges.

Hospital Improvements.—Two charitable institutions of the city will be greatly improved soon. The first is the Home for

Incurables, where a pavilion for the treatment of cancer is to be erected. The building will be of brick and be equipped with all devices for comfort and care of the patients. The second institution is the Episcopal Hospital, and estimates are being taken for the erection of the Aspinwall ward.

Lectures on Tropical Diseases.—Under the auspices of the University of Pennsylvania, Major Guy L. Edie, U. S. Army, is delivering a series of lectures on tropical diseases. His first lecture on March 23 was devoted principally to yellow fever. He described the general character, symptomatology and treatment of the disease, and devoted some time to the discussion of the part played by the mosquito in the propagation of this malady. He said that yellow fever could now be placed in the category of preventable diseases. In speaking of the mosquito he said that the decline of the hibernation period of the mosquito marked the spread of yellow fever. His second lecture was delivered on March 25, and the talk was devoted to the discussion of beri-beri, Asiatic cholera, and bubonic plague. Major Edie will deliver a series of ten lectures, two each week, on Wednesdays and Fridays. The medical profession of the city is invited to attend.

Health Report.—Typhoid fever shows no signs of abatement. Indeed, there is a slight increase this week over last week's high figures, those for the week drawing to a close being 148 cases and 17 deaths, compared with 141 cases, and 21 deaths for the previous week. There is also an increase in scarlet fever, total cases reported being 116, compared with 101 for the previous 7 days. There is a slight increase in the number of smallpox cases reported; 35 new cases were reported during the week, an increase of 5 over the preceding 7 days. This is attributed to a local outbreak of 11 cases in one section of the city. The deaths from all causes during the week number 585, being a decrease of 49 from those of last week, and an increase of 40 over those of the corresponding week of last year. Pneumonia's ravages have decreased but slightly since the first of the year, when the deaths each week were from 100 to 125. This exceeds the number of deaths caused by consumption, which heretofore have headed the death list in point of numbers. The deaths from consumption during the past seven days were 60.

Lecture to Teachers.—Dr. Jay F. Schamberg addressed the teachers and principals of the schools on medical inspection of the public school. He said that in the New York schools more than 3,000 children had been found with contagious diseases of the skin, and nearly 4,000 with diseases of the eye. He declared, therefore, that regular inspection by competent physicians was imperative to protect the health and welfare of school children. He pointed out the fact that it was a common observation that contagious diseases, such as scarlet fever, diphtheria and the like, increased after the opening of the schools, and decreased after the close. He said that children commonly attend school during the developmental periods of various contagious diseases, and that such patients are not only apt to communicate the disease to a considerable number of school children, but each child thus infected may carry the disease home and transmit the same to others. He said that Philadelphia was far behind in the matter of safeguarding the health of school children, but that the city was beginning to awake to the situation, and has just completed the organization of a medical corps, so that the inspection of school children will very shortly begin.

SOUTH DAKOTA.

Schools Reopened.—The public schools at Bridgewater, which were closed for three weeks on account of an epidemic of diphtheria, have been allowed to reopen, and public gatherings to be resumed.

Itinerant Appeals.—"Dr." Charles Cram, head of a medicine show company, who was arrested in Vermillion recently for selling medicine contrary to law, found guilty and fined $90, has appealed to the circuit court.

Uncertificated Oculist Guilty.—M. F. Yegge, Huron, has been found guilty of violating the state law regulating the practice of medicine, by practicing as an oculist and prefixing "Dr." to his name without first having obtained a certificate from the State Board of Medical Examiners.

Sixth District Society Meets.—Dr. E. Frank Reamer, Mitchell, secretary of the Sixth District South Dakota Medical Society, writes: The regular quarterly meeting of the Sixth District South Dakota Medical Society was held in Mitchell, March 3. There was a smaller attendance than usual, but some excellent papers were read and freely discussed. Dr. Van Buren Knott, Sioux City, Iowa, was the guest of the evening, and read a paper on "The Open Treatment of Simple Fractures." Two or three unusual clinical cases were presented by Drs. Bowen and Reamer. After the program a banquet was served at the Waverly Hotel. Medical organization in this district is very nearly complete, and the state generally is in good condition. The state association meets at Redfield June 1 and 2.

TENNESSEE.

Examinations.—The State Board of Medical Examiners will hold examinations in Knoxville, Memphis and Nashville, April 6 and 7.

Addition to Hospital.—The capacity of Mercy Hospital, Nashville, is to be increased by the addition of a new wing containing fifteen rooms, which will make room for 20 more patients.

City in Two States.—Dr. Hardin W. Reynolds, a homeopathic practitioner of Bristol, was fined $50 and costs on the charge of practicing medicine in Bristol, Va., without a license. Physicians in this state-line town are required to take out licenses in both Tennessee and Virginia.

To Enforce Law.—Four physicians of Bradley have been fined for violating the law requiring practitioners of medicine to have their licenses registered with the county clerk. In Chattanooga, 25 physicians were fined for the same offense: in Cocke county 17 warrants have been issued, and in Polk County 12 have paid fines, and some others have retired from practice. The attorney of the state board estimates that there are between 1,000 and 1,500 violators of the law in the state.

UTAH.

Salt Lake Deaths.—During 1903, 745 deaths occurred, a rate of 9.93 per 1,000. Of these 39 were due to diphtheria, 21 to typhoid fever, 8 to scarlet fever and 2 to smallpox..

Society Election.—At the annual meeting of Weber County Medical Society in Ogden, Dr. George A. Dickson was elected president; Dr. Chester E. Coulter, vice-president; Dr. Haymond J. Powers, treasurer; Dr. Amasa S. Condon, librarian, and Dr. Harry B. Forbes, secretary, all of Ogden.

Farmer's Doctor Fined.—Andrew Peterson of Logan, masquerading as "Dr." J. S. Gray of London, who has been victimizing farmers in the neighborhood of Ogden, was arrested, March 16, charged with practicing medicine without a certificate, and was fined $10, or ten days' imprisonment.

Would Collect Vital Statistics.—The State Board of Health is sending out circular letters to the different boards of county commissioners asking them to apportion their respective localities into health districts with suitable inspectors, and to appoint registrars for the collection and preservation of vital statistics. Sample blanks of death certificates accompany the circular letters.

GENERAL.

Second Congress of French-Speaking Physicians of America.—This congress is announced to convene, June 28, at Montreal, in the halls of Laval University.

The American Neurological Association will meet at St. Louis September 15 to 17, and this will be immediately followed by the sessions of the various medical departments of the Congress of Arts and Sciences, beginning September 19.

Inspect Panama Canal Route.—The members of the Panama Canal commission have left for Colon to inspect the route of the canal. They were accompanied by Col. William C. Gorgas, assistant surgeon general of the Army; Dr. Louis La Garde of the medical department of the Army, and Dr. John W. Ross, medical director of the Navy.

Navy Medical School Graduates.—Thirty-one members of the graduating class of the Navy Medical School received their diplomas, March 21, in the lecture hall of the National Museum. The presentation was by Mr. Charles H. Darling, Assistant Secretary of the Navy, and Secretary Moody made the principal address. Admiral Rixey followed with some practical advice.

CANADA.

To Furnish a Room.—The Victoria Trades and Labor Council will furnish a room in the Strathcona wing of the Royal Jubilee Hospital.

To Prevent Hospital Abuses.—Hereafter provincial patients will only be admitted to the Isolation Hospital at Victoria on guarantee of payment for same by the provincial government.

Hospital Crowded.—What to do with chronic patients at the Provincial Royal Jubilee Hospital, Victoria, is a matter of some concern. The number of patients admitted during February was 87, the number treated, 141.

New Consumption Hospital.—Calgary, N. W. T., is to have a sanatorium for the treatment of pulmonary tuberculosis under the charge of Dr. Ernest Wills. The climate around Calgary is considered excellent for the purpose.

A Hospital for Ottawa Consumptives.—Dr. Moore, secretary of the Canadian Association for the Prevention of Tuberculosis, states that the old Contagious Disease Hospital in Ottawa is to be converted into a sanitarium for consumptives. Negotiations are now under way, and a wealthy citizen of Ottawa has promised to donate the money to remodel the building.

Ontario Law and the X-Ray.—An Ontario high judge has just decided that the law can not force a man to submit to an *x*-ray examination. A farmer was suing the Toronto Street Railway for damages for injuries sustained in a street railway collision, and the company wanted to have the man submit to an *x*-ray examination. He refused, stating that he was afraid he might die under the operation, as he had read of a similar occurrence somewhere in the states.

Canada Retains the Cigarette.—A resolution was before the Canadian house of commons March 23, to prohibit the manufacture, importation and sale of cigarettes, which secured a rather long, if not profitable discussion. Last year a similar resolution was carried on a vote of 103 to 48, but owing to some irregularity in the measure it was subsequently ruled out. The sponsor of the measure this year quoted Sir William Hingston, Montreal, and Dr. Charles Sheard, M.H.O., Toronto, as representatives of the medical profession who had pointed out the dangers and evils of the habit of cigarette smoking. The production of cigarettes in Canada is increasing enormously, having gone up from 138,000,000 in 1902 to 178,000,000 in 1903. The resolution was opposed by both the prime minister, Sir Wilfrid Laurier and Mr. R. L. Borden, the leader of the opposition. No vote was taken thereon, and the subject is practically shelved for the present session, as according to the rules of the house it has been relegated to the bottom of the list.

FOREIGN.

Another Prize for Finsen.—The Edinburg University has bestowed the Cameron prize on Prof. Niels Finsen for the most important work in practical therapeutics of late years.

Memorial to Schede.—A memorial has recently been erected to Max Schede in the grounds of the clinic at Bonn, the seat of his labors since 1895. The address was delivered by his successor, Professor Bier.

Prize for Pamphlet on Tuberculosis.—Dr. M. Salomon has received the Alvarenga prize from the German Hufeland Society for his pamphlet on "Tuberculosis as a Disease of the Masses and Measures to Prevent it."

The Quadrennial Polish Medical Congress Postponed.—We learn inofficially that as seventy Polish physicians have left for the seat of war in the east, the congress announced to open at Lemberg in July has been abandoned for the present.

Ankylostomiasis in a German Garrison.—The new recruits entering the garrison at Metz last fall evidently brought ankylostomiasis with them as numerous cases have been discovered. The subjects frequently have to be dismissed as incapable of military service, even after long observation and treatment.

Koch's Tropical Research.—Robert Koch is prolonging his stay in South Africa for the purpose of studying a horse disease, the *Pferdesterbe*. He goes to Dar es Salam in April to introduce his method of treating the cattle plague, which has proved so effectual in southern Africa. He is expected in Berlin before the end of June, when his leave of absence expires.

Italian Physiologists as Senators.—Professor L. Luciani of Rome and Professor A. Mosso of Turin, both famed for physiologic research, have been appointed senators of the realm in Italy. Luciani is now 62 years of age, while Mosso is four years younger. Mosso was called to Moleschott's chair at Turin on the removal of the latter to Rome, while Luciani was Moleschott's successor at Rome.

Price of Diphtheria Antitoxin in Europe.—The new Behring Serum Institute which is planned for Germany is not to be a government institution to monopolize the production of serums, as it is considered best to leave their production in private hands to stimulate competition and perfection. The price of diphtheria antitoxin is high, a single dose costing about eighty-five cents, while in Denmark, where the production is a government monopoly, the dose costs only eight cents.

German Society for Repression of Venereal Disease.—The annual meeting of this new society was held at Berlin March 6. The membership has now reached 3,500, and there are twenty local branches in various German cities. The warning circular which has been distributed by the society among young men has been denounced by certain persons because it referred to preventive measures and advised that a physician should be consulted in regard to them. The critics asserted that this clause ought to be stricken out in the interests of morality, but after a long discussion the objections were withdrawn.

The Madeira Islands as a Health Resort.—Dr. Pannwitz of Charlottenburg is manager of the new German company formed to erect a sanatorium on one of the Madeira Islands. Prince Carl von Hohenlohe obtained the concession from the Portuguese government and a company has been formed with a capital of $200,000 to carry on the enterprise. The executive committee includes the physicians B. Fränkel of Halle, Rumpf of Friedrichshain, Wolf of Reiboldsgrun, Romer of Marburg, and Lencastre of Lisbon. The party sailed March 10 on the steamer "Eleonore Wormann" to Funchal to make arrangements for organizing a health resort on a large scale on this island.

Tribute to Professor Cornil of Paris.—The age limit—65—for the service as hospital physician having been reached, Cornil was retired last year, and his term of service in the senate expired at the same time, but he is still professor of pathologic anatomy, as for twenty-two years. His friends recently gathered to pay tribute to his life of devotion to science and progress. He was presented with a portrait medallion, and in his response dwelt on his life's ideal as "progress in all its forms, scientific, political and social." He urged that science and politics should join hands, each aids and supplements the other, and cited experiences to show the facility with which reforms can be realized when certain members of the profession are regarded as important factors in the political life of a country.

Silver Jubilee of the Cystoscope.—Prof. Max Nitze of Berlin received an ovation from his friends, pupils and fellow specialists the world around, March 9, 1904, the twenty fifth anniversary of the day on which he first exhibited his cystoscope before a medical society in Vienna. He was presented with an album containing the photographs of specialists in urology and also with a *Festschrift* and telegrams of congratulation signed by many specialists, surgeons, clinicians and gynecologists, as well as urologists of various countries. He is now in his fifty-sixth year, and notwithstanding the revolution in urology induced by his invention he has never received due academic recognition. He was 41 before he won the title of privat docent, and 52 before the position of professor extraordinary was conferred on him. Even now, as there is no chair of urology at Berlin, he has to deliver his lectures and train his pupils in his private establishment.

The Antimalaria Campaign of the Italian Red Cross Society.—The annual report just published reviews what has been accomplished during the four summer campaigns undertaken by this society. In 1900 about 31 per cent of the population in the ultramalarial districts contracted malaria. This proportion has been gradually reduced until last year only 11 per cent were affected. The first year the society had no quinin at its disposal, the second year it was able to give it to 925 patients, the third year to 1,272, and last year to 7,853. It had seven stations on the Campagna with 40 physicians and 32 nurses. Much better results would be attained if the society were able to keep up the quinin treatment during the winter, but the more than 12,000 laborers who flock to the Campagna during the harvest time scatter to all points of the compass afterward. The expense of the campaign last year was less than $9,000, part of which was contributed by the king and part by the city.

The Virchow Endowment Fund for Scientific Research.—On the occasion of Rudolf Virchow's sixtieth birthday about $20,000 was collected and presented to him as an endowment fund for scientific research. This sum was increased by various gifts and subscriptions until in 1901 it reached $36,000, and the further contributions at his eightieth birthday raised it by $16,000 more. This sum was placed entirely at his disposal, and since his death his heirs have formally given it over as an endowment fund to a board of seven trustees, to include five delegates from scientific societies, the mayor of Berlin, and a practical business man to serve as treasurer of the fund. The endowment states that the interest of the sum is to be applied to the aid of research in anthropology, ethnology, archeology, comparative philology and medical geography, by subsidies for travel, by aid in researches, excavations, etc., and in publication and illustration of works on these subjects or in the purchase of material, apparatus, etc. Such undertakings as have an established plan and estimate of expensès are to be given the preference.

The War from the Russian Medical Standpoint.—Dr. Weissbein, in an editorial in the *Russische med. Rundschau,* remarks that all entertainments have been abandoned in Russia, and attention is concentrated solely on the furtherance of the war and mitigation of its hardships. Physicians are giving public lectures to instruct the people in the principles of caring for the sick. Post-graduate courses in military surgery have been organized at all the universities and large numbers of physicians are hastening to the seat of war. It is generally understood that the conditions there are extremely unfavorable and that it will prove an arduous task to protect the soldiers against epidemics. Malaria prevails in the many swampy districts, and the unhygienic surroundings invite typhoid fever. Fortunately, he adds, the Russian soldier is extremely resistant and is able to undergo the severest hardships without losing courage. He is likewise accustomed to a vegetable diet and to deprivations of many kinds. The troops are well cared for on the long railroad trip, with abundance of hot tea and two warm meals a day. An army of trained nurses and attendants is ready to afford relief the moment its services are called on, and money is pouring in to supply every need.

Approaching International Congress of Ophthalmology.—The Journal, Aug. 22, 1903, page 503, published the particulars in regard to this congress, and due notice of the exhibition to be held therewith was given recently on page 720. The Swiss railways and boat lines offer low special rates to the members of the congress, and the town of Lucerne promises lavish hospitality. Owing to the death of Professor Pflüger the committee of organization now comprises Snellen of Utrecht, Barde of Geneva, M. Dufour of Lausanne, Haab of Zurich and E. Landolt of Paris, with Mellinger of Basle and Siegrist of Berne. The latter has charge of the exhibition, while the membership fee and all MS. should be sent to Professor Mellinger of Basle. Communications received before May 1 will be printed and distributed to members and discussed at the meetings. Those received after this date will be compelled to await their turn afterward. The printed summaries will be sent to the members with their tickets in receipt for the subscription ($5). The official opening has been advanced five days, and will be on September 13, instead of 18 as announced in the circulars first received. Accommodations at one of the best hotels at the rate of $1 a day (including early breakfast), can be secured by application to the chairman of the local committee, Dr. F. Stocker, of Lucerne, not later than September 1. Further information may be obtained from Dr. G. E. de Schweinitz, 1401 Locust Street, Philadelphia, the official correspondent for the United States.

DUBLIN LETTER.

The Consumptive Hospital.

The Royal National Hospital for Consumption for Ireland, which held its annual meeting a few days ago, is situated near Newcastle in County Wicklow, twenty-five miles from Dublin, in one of the most beautiful districts in Ireland. Founded eight years ago, it was the first "open-air" sanatorium in this country, and is still, with the exception of a small home near Belfast, the only one for poor patients. Of course, it is lamentably insufficient for the needs of Ireland, and this insufficiency tells injuriously on its own power of doing good. The hospital contains sixty-eight beds; 12,000 people die every year in Ireland from tubercular diseases. With the consequent enormous demand on its space the hospital has to fall back on the very doubtful expedient of limiting the stay of patients to a short period. The regulation time is fixed at ten weeks, though this is sometimes prolonged to sixteen or twenty in suitable cases. It is obvious that in such a short time as this little permanent good can be effected, for the treatment of tubercle has to be marked in months or years, not in weeks. At the same time the period is longer than is found possible in most hospitals for consumption in England, where six weeks is the usual period. Under the circumstances, sanatoria for the poor have but little power except in their educational capacity. They can teach patients the elementary facts of rational treatment, and the dangers of infection, and they can train them to follow hygienic modes of life. I fear, however, it is too often impossible, even for the most willing patients, to carry out their instructions fully on their return to domestic and business life. As it is, however, even in the short period allowed, Newcastle does excellent work. The annual report tells us that gain in weight is all but universal, and that at the time of their discharge many patients show no physical sign of disease. An interesting feature is the ward maintained by a manufacturing company for the use of their own employes, and patients in this ward are not affected by the usual limit of stay in the institution. The report of the company's medical officer, on the effects of the Newcastle treatment on his patients, is valuable testimony to the efficiency of the work that is done when there is no obnoxious time limit. Every one of the patients he had sent there had improved; several of them he believed cured; all had been, in his opinion, doomed to speedy death but for the treatment. The stay in hospital had varied from six to over twelve months. It is satisfactory that the hospital has enough funds to build a new wing, which will hold thirty beds for females. It is also intended to open an adjunct dispensary in Dublin where candidates for admission can be seen and former patients remain under treatment, and where advice—medical and educational—can be given to patients who are unsuitable for admission.

LONDON LETTER.

New Medical Buildings at Cambridge.

The new buildings erected in the University of Cambridge for the study of medicine, botany, geology and law, recently mentioned in The Journal, have been opened by the king, in the presence of a distinguished gathering, which included the presidents of the royal colleges of physicians and of surgeons, Sir W. Broadbent, Dr. Clifford Allbutt, regius professor of physic in the university, and Dr. Sims Woodhead, professor of pathology. As might be supposed, the accommodation for the study of medicine in this ancient university has fallen far behind modern requirements. The new buildings are thoroughly up to date and will be replete with every convenience. They are built of brick faced with Ancaster stone, and perfectly plain in style, without pretensions to architectural beauty, as is supposed to be fitting for a medical school. In the basement are workshops, storerooms, combustion and other experimental rooms, photographic rooms, engine house, electric lighting, heating and ventilation installations. On the ground floor are various private workrooms, large demonstration and examination rooms, the medical and surgical departments, and pharmacologic laboratories. There is a spacious entrance and staircase paved with black and white marble. At the foot of this staircase is a large lecture room capable of accommodating 200 students, while facing are the pathologic museum and two workrooms—one for pathology and the other, at present, for public health work. The lecture room receives practically no lighting from without, but is dependent on artificial light. This was done designedly so that all available light could be used for the workrooms. It was thought that in the lecture room artificial light would be better than natural light as the exact amount necessary for a demonstration could be focused on to map or screen and maintained there steadily. On the first floor is the Humphry Museum, so named after the late distinguished professor of surgery in the university. It is a finely proportioned room, 62 by 38 feet. The walls are lined with glazed tiles of a sea-green color, relieved with dull pink moldings. The cost of the museum was largely defrayed by subscriptions from Cambridge medical graduates, many of whom were pupils of the great Cambridge teacher. On the same floor is the library—a lofty room lighted from the top. An ingenious arrangement for stowing books in stacks has been adopted. Each separate block of cases is movable, allowing access to shelves behind, and a very large library to be housed in a moderate space. On this floor are also the private rooms of the regius professor of physic, a research room for members of his class, and an operating and a private room for the professor of surgery. On the second floor is a small museum for teaching purposes where the student will have access to all specimens and will be able to bring his text-books and note-books. Beyond this museum is a laboratory for pathologic chemistry, in connection with which is a photographic room. There are also a large practical class-room for morbid pathology lighted from the roof with accommodation for 90 students, and an incubating room. The greatest care has been taken in the details of equipment so as to provide the maximum of convenience for the worker. In the rooms for research and practical work hot and cold water, gas and electricity are laid on to every bench. The walls and ceilings are finished with a smooth concrete surface, all angles are rounded, and the walls join the ceilings and floors in curves, so that there are no corners for the collection of dirt. In his address the vice-chancellor of the university said that since the earliest times medicine had an honored place, and expressed the hope that it would now have a home worthy of its splendid progress in recent days. In replying the king said that he was confident that at Cambridge the progress would be continued, and that the old universities must succeed to new endowments for education if the realm was to be kept up to its proper standard of efficiency. In the library Prof. Sims Woodhead showed the working of the sliding bookcase, which he had chosen after seeing similar ones used in the United States. Pathologic specimens were arranged for the inspection of the king, who took particular interest in specimens of *Trypanosoma nagana* placed under a microscope.

Medical Education in London.

The great interest of the king in medical science is again shown by his communication to the Faculty of Medicine of the University of London in relation to the proposed institute of the medical sciences. Medical education in London has always been carried on by the various schools as a private enterprise, and is regarded by the public as so profitable that an appeal for funds is regarded by many as an impertinence. The recently established Polyclinic, the first attempt to provide graduate teaching on a large and systematic scale in London and to remove from the metropolis of the world the stigma of being far behind comparatively small continental cities, though badly in want of funds, has failed to appeal to the imagination of the philanthropic, and only has been able to get out of difficulties by donations from the profession. While munificent gifts can always be obtained for the needs of the sick poor it is thought that medical education is a matter entirely for the profession and one to be settled on business lines. The king has set an excellent example in abolishing this thoughtless view. To remedy the defects arising from the want of concentration of the teaching of the earlier subjects of the medical curriculum it is proposed to found an institute of the medical sciences. Last year the senate of the University of London appointed a committee of appeal to raise funds. At first it was determined not to make the appeal more public than was implied in sending a copy of it to every member of the faculty of medicine, in the hope that some individual or individuals of ample means might furnish sufficient to build and equip, if not to endow, the institute. This expectation was not realized. Then an appeal was made to the public through the lay press. When the matter came under the notice of the king he at once gave his support and contributed $520. The result of this will be a tremendous impetus to the fund, for in this country the public estimates individuals and things, not so much by their merits, as by the support and recognition they receive from persons in high social positions. The appeal has been most favorably received by the lay and medical press, and has been recommended by the treasurers of nine of the hospitals, to which medical schools are attached. Promises of contributions amounting to $40,000 have been received.

The Prevention of Consumption.

The fifth annual meeting of the National Association for the Prevention of Consumption has just been held. A very active campaign has been carried on. After a visit to Germany of a deputation from the National Conference of Friendly Societies to inquire into the German system of providing sanatorium treatment for the working class a further conference took place between the council of the association and delegates from the "Hospital Saturday Fund." The latter is a fund collected for the hospitals in the streets and workshops once a year on a particular Saturday. At the conference it was decided to form a national committee for the establishhment of sanatoria for workers suffering from tuberculosis. They have in the first instance been requested to ascertain the requirements of consumptive workers, the accommodations existing, and to suggest and organize a scheme for the promotion of such sanatorium accommodation as may be necessary. The council have done their best in the past five years to promote the voluntary notification of phthisis to the health officers throughout the country. This practice has been extending, and in Sheffield, owing to the strong representation by the health officer and one of the medical advisers of the local government board a committee of the house of commons recently sanctioned a corporation by-law for that city in which notification of pulmonary tuberculosis is made compulsory on every physician called on to visit a case. The report also gladly calls attention to the recent by-law of the London County Council prohibiting spitting in public places and carriages. As to the isolation of consumptive cases in workhouses and asylums, steps have been taken by some few boards of guardians to deal with the question not only of isolation, but of treatment, and with good results. With regard to consumption in the asylums for the insane a committee of the Medico-Psychological Association of Great Britain and Ireland have recently made a very full report, and suggestions which have received the approval of the council, who hope that the commissioners in lunacy will see that they are carried out. Considerable progress in the erection of sanatoria has been made during the year: there are now some 70 institutions in the United Kingdom containing 2,760 beds. This is an increase of 18 institutions and 375 beds over the return in October, 1902. But the majority of these institutions are for paying patients, and the need of providing accommodation for the poor is still urgent. The most important movement in connection with sanatorium work during the past year was the laying of the foundation of the King Edward VII Sanatorium, in Surrey, November 3, which has previously been described in The Journal. There are 935 members of the central association and 2,900 of the 20 branches, making a total of 3,835. In addition to these there are colonial branches or kindred associations in Canada, Victoria, New South Wales, South Australia, Natal, and Cape Colony. The movement for providing sanatoria accommodation for postal employes suffering from tuberculosis is making good progress. These employes suffer from tuberculosis in the proportion of 6 per 1,000. A proposal is on foot to establish 100 beds, to be increased later.

The Study of Tropical Diseases in Liverpool.

At the annual meeting of the Liverpool Royal Southern Hospital it was reported that 149 patients were admitted into the tropical diseases ward, against 137 and 131 in the years, 1902, and 1901, respectively. The majority of the patients were suffering from malarial diseases, other diseases being dysentery, beri-beri, bilharzia disease, craw-craw, etc. Students attend from all parts of the world—America, Chili, Spain, Portugal, Germany, Austria, Finland, Sweden and Norway.

Correspondence.

Osteotherapy in New York.

New York, March 26, 1904.

To the Editor:—A bill has been introduced in the legislature of the state of New York by Senator Fitzgerald, entitled "An Act to Define and Regulate the Practice of Osteotherapy." It is Senate bill No. 983, introductory No. 761, and has been referred to the committee on judiciary, of which Hon. Edgar T. Brackett is chairman.

This bill defines "osteotherapy" as follows: "The practice of osteotherapy is defined to be a system, method or science of healing disease without the use of drugs or medicine of any kind. It is based on the proven laws of anatomy and physiology, and comprises scientific and thorough knowledge of the structure and functions of the human mechanism, to apply certain organic laws and natural remedial resources, within the human organism itself, and by means of scientific manipulations and adjustment, assist nature, in harmonious accord with its own mechanical principles, activities and processes, to recover from displacements, derangements, obstructions and pressures, and to regain normal equilibrium of form, action and function, thus restoring to the patient normal health and strength. The word 'osteotherapy' is derived from the Greek ('osteon,' bone, and 'therapeia,' nature, healing). The word 'osteotherapy' is a correction of the word 'osteopath,' which latter means, translated from the Greek ('osteon,' bone, and 'pathy,' suffering), bone suffering. The word 'osteotherapy' embraces the science so-called osteopathy, the practice of massage and Swedish movements to its fullest extent, and any one practicing the latter sciences, under those or different names, shall come under the jurisdiction of this act."

It is difficult to imagine this as a serious effort to secure legislative enactment, for to read the definition is "to laugh"; but we must assume that the gentleman who introduced the bill was not actuated by the desire to amuse his colleagues. The measure goes on to provide for a board of examiners, appointed by the Regents of the University of the State of New York, for examination and registration fees, and so on. If physicians will write to the members of the Senate judiciary committee opposing this bill, its fate will not be long in doubt.

If you will publish this letter together with the inclosed reasons why "osteopathy" and allied "pathies" should not receive special recognition, it will bring the matter before the profession, and, I believe, aid those who are endeavoring to protect our professional standards. One of the arguments used at the public hearings before our legislature is that other states have enacted laws recognizing the practices of "osteopathy," "optometry," and other peculiar methods of treating disease. I can not believe that New York will ever enact similar laws unless some better reason than this is advanced. I do not believe that New York will enact any laws affecting the practice of the healing art unless the medical profession will indorse them. This opinion is the result of about eight years of more or less intimate acquaintance with our legislators, and, if it is correct, then, to use the language of the day, it is up to the medical profession to be alive to its responsibilities. Very truly yours,

Frank Van Fleet, M.D.,
Chairman Committee on Legislation of the Medical Society of the State of New York.

[The following are the reasons referred to above.]

REASONS WHY OSTEOPATHY, OSTEOTHERAPY AND OTHER PECULIAR METHODS OF TREATING DISEASE SHOULD NOT RECEIVE SPECIAL PRIVILEGES.

1. There are no methods of counteracting the results of disease, or of remedying or correcting physical defects, known to science, which are not known and practiced by qualified and competent physicians when such methods have in themselves any valuable properties.

2. The practice of medicine, or, to use the more comprehensive term, the treatment of disease, has not reached that degree of perfection where it is possible to say with exactness that a certain remedy is a certain cure under all conditions. Circumstances modify conditions, and it is only after weighing all the conditions present in a given case, and often after consultation with experts in special lines, that the remedy can be selected and properly applied; and even then, under what may seem to be the most favorable conditions, the results are not always satisfactory. Therefore, the state, recognizing how imperfect and uncertain the knowledge of the healing art is, has created a standard of proficiency with which all who desire the right to practice this art must comply. Not that such practitioners may be able to treat certain diseases; not with the idea of creating certain classes of practitioners, but with the single idea that all who hold themselves out as competent to practice the healing art shall have sufficient knowledge to recognize and discriminate the various diseases and defects, and to be familiar with and able to apply the known remedies. The state places in the hands of practitioners of the healing art extraordinary discretionary power; after receiving this power from the state these practitioners are responsible to nobody but themselves for the conscientious discharge of their duties. It would be manifestly improper for the law-making powers to confer privileges such as these on any but the most competent in order to make them as little a menace to the community as possible.

3. Osteopaths, or osteotherapaths, claim that the method they employ is not the practice of medicine. The person, be he supreme court judge or an ordinary citizen, who claims that the practice of medicine necessarily implies the giving of medicine or drugs, must have a very limited knowledge of the work of physicians. There are many physicians who have received the privilege from the state to practice medicine, and who would deny they were anything but practitioners of medicine, who rarely resort to drugs in the treatment of the affections they have to deal with. Indeed, it is quite as much the function of the medical practitioner to give advice as it is to give medicine; to apply other forms of treatment, as bath, rubbings, massage and manipulations, as it is to apply drugs. There is an ever-growing tendency to give fewer and fewer drugs in the treatment of disease, but no educated physician would be willing to undertake the treatment of any form of disease if he was denied the privilege of giving drugs and medicines if they seemed to be indicated, or indeed to be restricted in his treatment of disease to the employment of any one method. Whether the treatment of disease is the practice of medicine or not, one thing is certain: osteopaths and osteotherapaths desire the privilege possessed by licensed physicians, that of treating diseases. Not one disease, or any particular class or type of disease; they desire the right to undertake the treatment of all diseases, defects and infirmities indiscriminately, as physicians do, except that they are willing to be restricted to the employment of one method of treatment. This, as already stated, is in itself sufficient to condemn them as indicating the absence of knowledge of the scientific discoveries of the present time. No conscientious and educated physician would be willing to submit to a restriction of this kind.

4. The so-called theories of the so-called osteopaths or osteotherapaths, are positively dangerous. For example: They have recorded themselves at the hearings before the legislature of New York and other states as not believing in the contagiousness of certain diseases, as smallpox, scarlet fever, erysipelas, and so on. With this ignorance they would not realize the necessity for disinfection, and would go directly from attendance on a case of this kind to deliver a pregnant woman, and the result might be disastrous.

The denial of the value of antitoxins, of vaccination, and of the necessity for isolation and disinfection, together with the teaching of doctrines entirely at variance with accepted scientific facts, stamps these people as positively dangerous to the community. That they should ask the state to create a standard for them less rigid than that with which physicians generally have to comply, is evidence itself that their motive is neither honest nor honorable. If osteopaths, or osteotherapaths, really and honestly believed they were possessed of a knowledge, or had a method of treating diseases superior to the knowledge or methods of other physicians, they would not constantly endeavor to secure the legal right to employ their methods by compliance with a standard less than that already demanded by the state. The logical course to pursue would be to comply with the existing standard, and then demonstrate the superiority of their methods.

5. Osteopaths, or osteotherapaths, claim an extraordinary knowledge of anatomy and chemistry. If such a claim is a truthful one, it does not stamp the possessors of such knowledge as competent to practice the healing art. A knowledge of physiology and pathology is even more important and necessary. It will not do to say one does not believe in the accepted views of pathology and etiology unless one has a knowledge of them, and one can not have a knowledge of these branches unless one has devoted sufficient time to their study to acquire it. If four years of study are necessary to prepare and properly equip physicians, and osteopaths, or osteotherapaths, can secure the legal right to undertake the treatment of disease after only two years of preparation, some other class of practitioners will doubtless appear and urge, with equal reason and justice, that only one year of preparation is necessary to properly fit one to practice their method. It will not do for the state to discriminate; if any standard is necessary at all, it should be made to apply to all alike. Either this must be done, or, in justice to all practitioners of the healing art, all standards should be abolished, and the field thrown open to all comers. The latter course would be best for the doctors, but not so good for the community. The public generally can have but a limited knowledge of what is best in the way of remedies and methods in the treatment of disease. For its own protection the state creates medical laws, and, instead of lessening the requirements of these laws at the request of all sorts of fakirs who may come along, it would be better to make the requirements more rigid, and make the penalty for violation of the common law so severe and so easily enforced that quacks and charlatans of all kinds would keep clear of the state of New York.

Effect of Potassium Iodid on Urine.

Philadelphia, March 22, 1904.

To the Editor:—The following case is reported as a clinical note, not because it presents new or unusual features, but because it brings into question the propriety of a very common method of administration of one of our most commonly used drugs, and also because the reaction obtained in a specimen of the urine may not be familiar to all of your readers. The urine referred to was from a young tuberculous subject, whose case was observed in the Methodist Hospital in Philadelphia. The resident physician, Dr. Richmond, noted that on boiling the urine and adding a small quantity of nitric acid the fluid first assumed a deep claret color, and later, on the further addition of acid, a purplish tint which colored the foam and the fumes a brilliant purple also. At first it was suspected that the reaction was one to which attention has been repeatedly called by different observers, of a pink coloration produced by the addition of nitric acid to the urine of certain tuberculous patients. It was found, however, that this patient was receiving thirty grains of potassium iodid three times daily, and further tests showed that the reaction was undoubtedly due to the presence of iodin salts in the urine. After the addition of starch the urine became a dark blue at once upon adding a drop of nitric acid. This reaction occurred when the starch powder was suspended in the foam as actively as when the urine itself was tested. On further heating the specimen, to which nitric acid only (and no starch) had been added, the purple color was soon discharged, and on still further heating and the addition of small quantities of the acid the color became first amber, then yellow, and finally retained but the faintest tinge of straw color. The reaction appears of practical interest as indicating the excretion of excessive amounts of the drug, and amounts probably in excess of those assimilable by the system, even though there were no symptoms of iodism present. The discharge of iodin or its salts in the foam and vapor also suggests the possibility that in the formation of KI solutions by the druggist according to the customary methods much less of the drug is retained in the solution than is supposed, and much less, therefore, is administered in the drop dosage than is intended.

Robert N. Willson, Jr.

Hospital Experience Necessary for Licensure.

Somers, Mont., March 22, 1904.

To the Editor:—In the March 19 edition of The Journal, Dr. F. C. Bennett discusses the advisability of a compulsory interneship. He certainly makes some unwarranted statements. He says that none but sons of the wealthy can avail themselves of such a training. From my own personal experience, I know that a poor man can have a hospital training and I know many others beside myself who were poor, yet who spent a year or eighteen months in a hospital. I have practiced for a year in the backwoods of Montana and never yet have I been able to see where my hospital training hindered me. In fact, I have many times been thankful I have had such training. I can not conceive of a case in which a student fresh from college would have the advantage over a hospital-trained man. F. B. Bogardus, M.D.

PATENT MEDICINES BARRED IN SWEDEN.

Pittsburg, Pa., March 23, 1904.

To the Editor:—I read the following in a local newspaper:

"*Patent Medicines Barred in Sweden; Pink Pills and the Like Not Wanted. Only One Druggist to Every 15,000 Persons.*

"Washington, March 22, 1904.

"Patent medicine men in the United States had best keep away from Sweden. This warning has been sent them by Minister Thomas, at Stockholm. Not a patent pill, bottle or preparation can now be obtained in the kingdom and the 350 apothecaries that control the medicine business of the entire country declare they will not handle any of that kind of trade. The importation of patent medicines, Minister Thomas says, would probably be followed by punishment of the offender and the confiscation of the medicines. In Sweden there is only one druggist to every 15,000 people, and the members of the profession consider themselves, Minister Thomas says, 'public officers and, in some sense, the guardians of the public health.'"

Blessed Sweden! What a boon such legislation would be to enlightened (?) America. Who among us has not felt the harassing effects of reckless, unscrupulous, almost criminal and certainly illegal dispensing and practicing by druggists? And worse still, in how many scores of cases have we seen the unhappy results of such practicing on our patients? Bad enough to thrust these countless hundreds of "patent medicines" (patent poisons many) on an ignorant and gullible public and flaunt their advertisements in our faces at every turn. But to have our druggists, who *should* be "guardians of the public health," urge the suffering patient to use his wares, knowing that many of them are either worthless or injurious, and often even dissuading him from consulting a physician, is indeed a disgrace to our beloved country. Is there no remedy? J. M.

ACID DUODENAL MEDICATION.

Atlanta, Ga., March 22, 1904.

To the Editor:—I read on page 804 of The Journal, March 19, an abstract on "Acid Duodenal Medication." I have some patients who need just this treatment. I can not get the tartaric acid in gluten-coated capsules here. Can you tell me where these can be obtained and how much Dr. Enriquez gives the patient? I am very much interested in this treatment and will thank you very much for all the information you may give me on this line.

J. E. Ashcraft.

Answer.—We are unable to learn of any drug firm that makes such a pill, but any of them will make the pills to order. Perhaps your druggist can do it. Dr. Ed. Enriquez states that he obtained satisfactory results from the simple ingestion of a 3 per cent. hydrochloric acid "lemonade," sipped every fifteen minutes at the time when the duodenal medication may be assumed to be most needed, approximately three to four hours after meals. This proved particularly effective in the cases that may be called neuromotor dyspepsia. It was in attempting to improve on this method that he hit on the idea of the more localized acid duodenal treatment by the gluten-coated capsules of tartaric acid. They were made for him by Dr. Carrion, chief of the laboratory at the Saint-Antoine Hospital, Paris. Dr. Enriquez does not seem to think that the tartaric acid has any special advantages; he merely happened to select that acid. In his published communication on the subject there is no mention of the dosage.

SALE OF PRACTICE.

Cedar Springs, Mich., March 22, 1904.

To the Editor:—I made a verbal agreement to buy another physician out, buying his good will, drugs, furniture in office, office building and house and lot. I paid him $200 to apply on account and took his receipt. He took me into his office and introduced me to his patients for nearly three months. When the time for settlement came his wife refused to sign the deed, having changed her mind in regard to moving. Now I am suing him to fulfill contract. I am told that The Journal contained a decision bearing on almost a similar case. I take The Journal, but did not happen to see it. Can you give me any information on the subject?

Chas. W. Brayman, M.D.

Answer.—Consult The Journal, Sept. 19, 1903, page 735; Nov. 28, 1903, page 1364; Jan. 9, 1904, page 122.

TO REMOVE FRECKLES.

Caldwell, Kan., March 23, 1904.

To the Editor:—Please give me a prescription for removing freckles, either by drugs or mechanical. D. E. K.

Answer.—Stevens recommends the following, applied twice daily:

℞. Hydrarg. chlor. corros................gr. iv to viii
Alcoholis et aquæ, of each q. s. ad............℥iv

Bartholow suggests:

℞. Potassii carbonat............................ʒiii
Sodii chloridi..................................ʒii
Aquæ rosæ.....................................℥viii
Aquæ aurantii flor.............................℥ii
M. Sig. Use as a lotion.

Remember that freckles usually return after removal.

LATENT GONORRHEA OR SIMPLE URETHRITIS.

Macon, Ga., March 20, 1904.

To the Editor:—Can a genuine gonorrhea be present when all the symptoms are present and are very marked, but when a careful microscopic examination shows no gonococci, but an abundance of staphylococci? G. W. Roberson, M.D.

Answer.—Yes. It may be hidden and the gonococci may appear under excitement or after drinking intoxicants. On the other hand, this may be a non-specific urethritis. What the physician should advise in such a case is one of the most delicate problems that comes to him.

PROMPT SETTLEMENT OF PHYSICIANS' BILLS.

We have been shown a receipted bill from a physician in the southwest on which the following is printed: "A PROMPT SETTLEMENT of this bill is requested and expected. If bills are paid monthly a discount of 10 per cent. is given. Bills not paid promptly will be passed to my attorney for collection, unless by special agreement. If you pay your physician promptly he will attend you promptly, night or day, rain or shine, while your slow-going neighbor suffers and waits, as he made the doctor wait; and while he is waiting the Angels gather him in."

WISCONSIN BOARD.

Dr. N. A. R.: The secretary of the Wisconsin State Board of Registration in Medicine is Dr. Filip A. Forsbeck, Milwaukee.

Marriages.

G. E. Milton Smith, M.D., to Mrs. Margareta M. Smith, at Baltimore, March 23.

G. Wishart Slater, M.D., to Mrs. M. L. Rabold, both of Baltimore, March 16.

Marcus Feingold, M.D., to Miss Birdie Lowenberg, both of New Orleans, March 23.

Robert J. Rivers, M.D., Paducah, Ky., to Miss Janet Bush of Smithland, Ky., March 22.

John Stewart Kulp, M.D., U. S. Army, to Miss Zoe Worthington-Smith, at Philadelphia, March 23.

Deaths.

Elisha Peckham Clarke, M.D. Medical School of Maine, at Bowdoin College, Brunswick, 1863, fellow of the Rhode Island Medical Society, and its president in 1895 and 1896; president of the South County Medical Society in 1878; state senator in 1878, 1879 and 1880; medical examiner for the town of Hopkinton; surgeon in the Thirty-first Massachusetts Volunteer Infantry in the Civil War, died at his home in Hope Valley, R. I., March 17, after an illness of several weeks, aged 70.

Aaron Rysing Gleason, M.D. University of Georgetown, Washington, D. C., 1864, hospital steward and assistant surgeon during the Civil War, a member of the American Medical Association, member of the New Hampshire legislature in 1897;

fellow of the New Hampshire Medical Society, and a member of the Cheshire County Medical Society, died at his home in Keene, N. H., March 4, from pneumonia, after an illness of three days, aged 68.

Abraham H. Hunt, M.D. Long Island College Hospital, Brooklyn, 1862, a member of the American Medical Association; surgeon during the Civil War, and for many years prominent as a surgeon in Wooster, Ohio, died at his home in that city, March 16, from heart disease, after a prolonged illness.

Henry C. Gemmill, M.D. Rush Medical College, Chicago, 1868, a member of the American Medical Association, Huntington County Medical Society, and Indiana State Medical Society, died at his home in Markle, Ind., March 18, after an illness of several months, from chronic nephritis.

Farquhard Campbell, M.D. University of Michigan, Ann Arbor, 1883, for eight years superintendent of the Osawatomie State Hospital, was stricken with apoplexy at his office in Kansas City, Kan., March 17, and died at Bethany Hospital four hours later, aged 47.

John Chester Lyman, M.D. Harvard University Medical School, Boston, 1872, who retired from practice nearly 20 years ago, died at the German-American Hospital, Chicago, from valvular heart disease, after an illness of about six months, March 29, aged 53.

Amos Seip, M.D. University of Pennsylvania, Philadelphia, 1848, one of the founders of the Northampton County Medical Society, in which he had filled practically every office, died from paralysis at his home in Easton, Pa., March 21, aged 81.

Fred A. Fanyo, M.D. University of Illinois, Chicago, 1903, of Watseka, Ill., an interne at Cook County Hospital, Chicago, assistant to the chair of clinical diagnosis in his alma mater, died at the hospital, March 22, from pneumonia, aged 26.

Derrick P. January, M.D. Tulane University, New Orleans, 1860, a surgeon in the Confederate service during the Civil War, died at his home in Crowley, La., March 17, from cerebral [illegible]rrhage, after an illness of a few hours, aged 65.

Frank H. McElroy, M.D. Tufts College Medical School, Boston, 1903, assistant pathologist to the Rhode Island Hospital, a bacteriologist of promise, died at his home in Providence, R. I., March 18, after a brief illness, aged 26.

Josias S. Duff, M.D. Columbus (Ohio) Medical College, 1881; Bellevue Hospital Medical College, New York, 1888, died recently at his home in Allegheny, Pa., from carbolic acid, accidentally taken, aged 49.

Thomas R. McInnes, M.D. Toronto (Ont.) University Medical Faculty, 1869, formerly senator and lieutenant governor of British Columbia, died recently from heart disease at his home in Victoria, B. C.

Myron Northrup, M.D. Geneva (N. Y.) Medical College, 1859, for 33 years a resident, and in 1886 mayor of Port Huron, Mich., died at his home in that city, March 15, aged 67.

Alanson P. Burch, M.D. Wooster University, Cleveland, 1888. of Toledo, died from paralysis at the Toledo Infirmary, March 21, after an invalidism of four years, aged 67.

Edward N. Gerard, M.D. Medical Department of the University of Iowa, Keokuk, 1861, died at his home in Mesa, Ariz., March 18, after a long illness, aged 67.

Adolph O. Heiberg, M.D. Jefferson Medical College, Philadelphia, 1893, of Rushford, Minn., died at Northfield, Minn., March 18.

J. G. Cannon, M.D. Physio-Eclectic Medical College, Cincinnati, 1876, died at his home in Yuba City, Cal., March 17, aged 78.

Augustus J. Fuchs, M.D. Jefferson Medical College, Philadelphia, 1876, died at his home in Mascoutah, Ill., March 14, aged 56.

William Mosby Mercer, M.D., a surgeon in the Confederate service during the Civil War, died in Baltimore, March 24, aged 76.

William Goodall, M.D. Illinois, 1878, died at his home in Chicago, recently, from disease of the stomach, aged about 60.

Gabriel Henry Chabot, M.D. University of Maryland, Baltimore, 1883, died at his home in Baltimore, March 23, aged 43.

Frank I. Phillips, M.D. Detroit Medical College, 1882, died at his home in Escanaba, Mich., March 22, after a long illness.

Benjamin F. Taylor, M.D. Missouri Medical College, St. Louis, 1843, died at his home in New Orleans, March 18, aged 79.

Michael Mason, M.D. Tennessee, 1864; Michigan, 1890, died at his home in Muskegon Heights, Mich., March 23.

Joseph S. Tweddle, M.D. University of the Victoria College, Cobourg, Ont., 1889, died suddenly at his home in Sturgeon Bay, Wis., after an illness of several months.

Book Notices.

DISEASES OF THE EYE. By L. Webster Fox, A.M., M.D., Professor of [illegible] Medico-Chirurgical College of Philadelphia. [illegible] 'lates and 296 Illustrations in the Text. Cl[illegible], $4.00. New York and London: D. Appleton & Co. 1904.

This book is dedicated to the memory of Ludwig Mauthner of the University of Vienna, the author's teacher, who he describes as the greatest operator of his day. The author declares that the treatise is the outgrowth of a series of lectures delivered during the last ten years at the Medico-Chirurgical College and Hospital. The book is, therefore, of a practical character, is divested of hazy theories, and is written in a plain and masterful manner. Of course, a great deal of the book is necessarily a rehash of other books, but Dr. Fox has brought each subject thoroughly up to date. It is a valuable addition to ophthalmologic literature, and will be of especial value to the student and general practitioner, who desire to keep well posted in this special avenue of labor. Considerable space is justly given to the therapeutics of the *x*-ray, which, considering the growing interest in this subject, will be appreciated by the reader. The book is well and comprehensively indexed, and also possesses a most intelligible glossary of all necessary ophthalmologic names and expressions. There are many good and new illustrations, and some old and bad ones. It seems strange that in a new text-book, with all modern facilities for photography, drawings and colored impressions, that it is still necessary to give place to such time-honored illustrations as may be found scattered through this as well as through all other modern works on ophthalmology. Still it can be truthfully said of the book under review that there are fewer ancient pictures within its covers than are to be found in any other ophthalmologic text-book with which we are familiar. Miss Washington's colored drawings are, as usual, the best of their kind. The author's large and varied experience, combined with a natural surgical intuition and enthusiasm, and with a decided ability to write and describe what he has to say, in clear, distinct, comprehensive language, serves to render this text-book one of real value to all students, ophthalmologists and general practitioners.

PORTFOLIO OF DERMOCHROMES. By Professor Jacobi of Freiburg im Breisgau. English Adaptation of Text by J. J. Pringle, M.B., F.R.C.P., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Volume II. Leather and Cloth. Pp. 181. Price per set, $15.00. New York: Rebman Company. 1903.

The diagnosis of skin diseases, even by the specialist, is often a difficulty, and the general practitioner frequently meets cases that are more than puzzling. To describe in words the characteristics of most of the skin infections is an impossibility, and for this reason all works on this subject, if not accompanied with illustrations, are deficient. And even then, simply black and white pictures are usually unsatisfactory. The recent development of three and four color printing has made it possible to show practically true to nature every kind of eruption. The second volume of Jacobi's atlas of skin diseases has, like the first, illustrations of this character; they show the disease exactly as it appears to the eye. The work, as a whole, is intended for the general practitioner, and consequently includes the commoner forms of skin diseases, and not the unique and rare. The exanthemata—such as scarlatina, measles, smallpox, etc.—are all covered. While the value of the work rests principally in its illustrations, yet the accompanying text will be found satisfactory. It is clear and to the point, and, while not voluminous, it contains sufficient details and descriptive matter relative to clinical features, prognosis and treatment to make the work reasonably complete in itself, and one that can be commended to those who desire an atlas in skin diseases. *It is* to be regretted that an index is not included; a book of this character should be one of ready reference, but this is impossible without a good index.

Hegele's Physicians' Account Record. A Card Index Record for Keeping Physicians' Accounts, Appointments, Records and Memoranda; Consisting of a Daily Record Card for Each Day in the Year, and a Yearly Account Card for Each Family or Patient, Contained in a Specially Constructed Wood Tray with Monthly, Daily, Alphabetical and Open and Closed Account Guide Cards, Together with an Imported Seal Leather Prescription Book and Card Holder. Complete $10. Trial Offer $5. Chicago: Box A 1055, Hegele's Physicians' Account Record.

This is not a book, but it takes the place of the books which most physicians use for the purpose. Card index records are taking the place of ledgers, journals and blank books throughout the business world to a marked degree because of their superiority. This card index record is asserted to be an entirely new and modern method for keeping physicians' accounts, records, appointments and memoranda, and if we accept the warm recommendations of some of the prominent physicians and surgeons who have used it, it will be a valuable addition to any practitioner's equipment. A description is of little value without the cards to illustrate it, so we will merely say that this record seems very simple, accessible and practical and so compact, complete, easily kept and accurate that it is said to entirely overcome all difficulties of that bane of existence, "bookkeeping," and to stand the test of the courts. There is very little writing to be done, as the record itself is gotten up in so complete a manner that it does away with the usual amount of writing necessary with the old methods of keeping books and use of signs.

Essential of Pelvic Diagnosis with Illustrative Cases. By E. Stanmore Bishop, F.R.C.S. Eng., Hon. Surg. Ancoats Hospital, Manchester. And an Appendix on Examination of Blood, etc. By Chas. H. Melland, M.D., (Lond.) M.R.C.P., Hon. Physician Ancoats Hospital, Manchester. Cloth. Pp. 297. Price, $3.00 net. New York: William Wood & Co. 1903.

This volume, which does not pretend to supplant the regular works on gynecology, is simply a statement of the principal diagnostic points that are to be observed from the viewpoint of the practitioner, who sees the symptoms without necessarily a previous knowledge of the disease. The inductive rather than the deductive method, is followed, and the plan appears a good one, though it is not new. The book is divided into five parts: 1, Pelvic diagnosis, giving the methods; 2, lines of diagnosis, describing the symptoms; 3, diagnostic tables, in which the symptoms are grouped and tabulated according to the conditions which they should indicate; 4, illustrative cases to demonstrate the manner in which the foregoing data should be employed; 5, a useful though brief description of the blood examinations and methods. The work has an excellent index, in which each subject has given in parallel columns the pages on which it is treated in the various subdivisions of the work—a plan which we have not heretofore seen adopted.

A Text-Book of Legal Medicine and Toxicology. Edited by Frederick Peterson, M.D., Chief of Clinic, Nervous Department of the College of Physicians and Surgeons, New York; and Walter S. Haines, M.D., Professor of Chemistry, Pharmacy and Toxicology, Rush Medical College, in Affiliation with the University of Chicago. In Two Volumes. Fully Illustrated. Cloth. Vol. II. Pp. 750. Price, $5.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The first volume of Peterson and Haines' work on medicolegal medicine has already been noticed. This second volume keeps up the character of the first. The editors have been able to obtain a very competent corps of collaborators on the various subjects included. In the first section of the work the subjects of malingering, questions of pregnancy and venereal diseases, birth, legitimacy, etc., marriage, divorce, malpractice, laws relating to insanity and the medicolegal relations of the *x*-rays are all treated of. The second portion is devoted to toxicology, as well as the medicolegal examination of the blood, seminal stains, etc. The book is fully illustrated, ample in its elaborate references and will undoubtedly be long a standard work of reference on this subject.

Blood-Pressure in Surgery, An Experimental and Clinical Research. The Cartwright Prize Essay for 1903. By George W. Crile, A.M., M.D., Professor of Clinical Surgery, Western Reserve Medical College. Cloth. Pp. 422. Price, $4.00. Philadelphia and London: J. B. Lippincott Co. 1903.

This volume contains the account of Crile's experiments on blood pressure and shock, and the details fill the greater portion of its pages. The practical importance of his results is evident, especially as regards operative surgery. As he says in the final summary: "In many instances the control of the blood pressure is the control of life itself," and he demonstrates that by proper methods of controlling it we may almost resuscitate the dead. The facts that a decapitated dog was kept alive as regards its vegetative functions for many hours, and the partial resuscitation of a man who had died from fatal injury of the brain, are indications of the possibilities of the method here described. The fact that the memoir has received the Cartwright prize, is sufficient evidence of its merit. The author is careful to state that all his experiments were conducted under full anesthesia, thus forestalling the criticisms of the antivivisectionists.

International Clinics. A Quarterly of Illustrated Clinical Lectures [illegible] Articles on Treatment, Medicine, [illegible] Obstetrics, Gynecology, Orthopedic[illegible] [illegible]almology, Otology, Rhinology, Laryn[illegible] [illegible]s of Interest to Students and Pract[illegible] of the Medical Profession Throughout the World. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, with the [illegible] [illegible] Osler, M.D., Baltimore; John H. Musser [illegible] Jas. Stewart, M.D., Montreal; J. B. Murp[illegible] A. McPhedran, M.D., Toronto; Thos. M. Rot[illegible] John G. Clark, M.D., Philadelphia; James J. [illegible]rk; J. W. Ballantyne, M.D., Edinburgh: John Harold, M.D., London; Edmund Landolt, M.D., Paris, and Richard Kretz, M.D., Vienna. With Regular Correspondents in Montreal, London, Paris, Berlin, Vienna, Leipsic, Brussels and Carlsbad. Vol. IV. Thirteenth Series, 1904. Cloth. Pp. 321. Price, $2.00 net. Philadelphia: J. B. Lippincitt Co. 1904.

This serial appears with its usual excellent collection of contents covering special subjects in the departments of general treatment, medicine, surgery, gynecology, neurology, orthopedics, ophthalmology and pathology. The list of authors includes not merely American, but also prominent European authorities, such as Julien, Dyce Duckworth and others. It is unnecessary to say anything further to commend the work. The series can be profitably read by the average practitioner.

A Short Practice of Gynecology. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. (Dublin Univer[illegible]), F.R.C.P.I., L.M.; Ex-assistant Master, Rot[illegible] [illegible] Second Edition, Revised and Enlarged. With 223 [illegible] Cloth. Pp. 406. Price, $3.75. London: J. & A. Churchill. *Philadelphia*: P. Blakiston's Son & Co. 1903.

This is the second edition of an English work, which is a very fair example of the briefer treatises on this important subject. We can not call it an exhaustive one nor recommend it in place of the fuller works. While its handling of the subject is generally judicious, and the illustrations and descriptions are clear, it does not meet the requirements either of the specialist or of the general practitioner.

Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. By Prof. Dr. Carl von Noorden, Physician in Chief to the City Hospital, Frankfurt a. M. Authorized American Edition Translated under the Direction of Boardman Reed, M.D., Professor of Diseases of the Gastro-intestinal Tract, Hygiene and Climatology, Department of Medicine, Temple College. Part IV. The Acid Autointoxications. By Prof. Dr. Carl von Noorden and Dr. Mohr. Cloth. Pp. 80. Price 50 cents. New York: E. B. Treat & Co. 1903.

Dr. Boardman Reed has done a service to American readers in having von Noorden's studies translated into English. In this little volume the acid intoxications are taken up and treated as the author's reputation might lead us to expect. The translation is well done.

The Gazette Pocket Speller and Definer. English and Medical. Second Edition. Flexible Leather. Pp. 216. Price 50 cents. New York: The Gazette Publishing Co.

This little dictionary, which the compiler says is intended primarily as a speller, is very handy and will doubtles be received with favor by the general, and especially the medical, public. Nearly half of the work is a medical dictionary and while, of course, it is not so full as others, it contains the larger portion of the medical terms which are sought for by the reader for information as regards definitions and spelling. The type is good, it seems to be free from errors and is a very convenient vest-pocket reference book.

The Practice of M[illegible] [illegible]or Practitioners and Students, with [illegible] [illegible]ls and Treatment. By James Tyson [illegible] [illegible] in the University of Pennsylvania. Rewritten. Wit[illegible] [illegible]evised and in Parts Cloth. Pp. 1,24[illegible] [illegible]g Colored Plates. & Co. 1903. [illegible] P. Blakiston's Son

The third edition of Tyson's Practice has been revised in certain points and the author has sought to make its contents represent the more important ideas in medicine. The enlargement has been mainly in the treatment of infectious diseases and he has had the chapter on nervous diseases carefully revised by so competent a neurologist as William G. Spiller, which guarantees its accuracy and fullness to date. Another subject which has also had revision is that of dysentery, it being carefully revised by Dr. Simon Flexner, one of the first authorities on the subject. In its present form the book is one that can be safely recommended.

Miscellany.

THE HEYBURN PURE FOOD AND DRUG BILL.

Text of the Bill in Full, with Comments by the Author of this Important Measure.

Four weeks ago we gave an abstract of this bill, but it is of such great importance to the public and to the profession that we give it in full. It is known as H. R. 6295, Calender No. 1165. The following is the bill:

AN ACT.

For preventing the adulteration or misbranding of foods or drugs, and for regulating traffic therein, and for other purposes:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the introduction into any State or Territory, the District of Columbia, or insular possession from any other State or Territory, the District of Columbia, or insular possession, or from any foreign country, or shipment to any foreign country of any article of food or drugs which is adulterated or misbranded within the meaning of this Act is hereby prohibited; and any person who shall ship or deliver for shipment from any State or Territory, the District of Columbia, or insular possession to any other State or Territory, the District of Columbia, or insular possession, or to a foreign country, or who shall receive in any State or Territory, the District of Columbia, or insular possession from any other State or Territory, the District of Columbia, or insular possession, or foreign country, or who, having received, shall deliver in original unbroken packages for pay or otherwise, or offer to deliver to any other person y such article so adulterated or misbranded within the meaning f this Act, or any person who shall sell or offer for sale in the District of Columbia, the Territories, or insular possessions of the United States such adulterated or misbranded foods or drugs, or who shall export or offer to export the same to any foreign country, shall be guilty of a misdemeanor, and for such offense be fined not exceeding two hundred dollars for the first offense, and for each subsequent offense not exceeding three hundred dollars, or be imprisoned not exceeding one year, or both, in the discretion of the court.

Sec. 2. That the Chief of the Bureau of Chemistry in the Department of Agriculture shall make or cause to be made, under rules and regulations to be prescribed by the Secretary of Agriculture, examinations of specimens of foods and drugs offered for sale in original unbroken packages in the District of Columbia, in any Territory or insular possession, or in any State other than that in which they shall have been respectively manufactured or produced, or from any foreign country, or intended for shipment to any foreign country, which may be collected from time to time in various parts of the country. If it shall appear from any such examination that any of the provisions of this Act have been violated, the Secretary of Agriculture shall cause notice to be given to the parties concerned with opportunity to be heard under such rules and regulations as may be prescribed by the Secretary of Agriculture, and if after such hearing it is found that any of the provisions of this Act have been violated, then the Secretary of Agriculture shall at once certify the facts to the proper United States district attorney, with a copy of the results of the analyses, or examination, duly authenticated by the analyst, or officer making such examination under oath.

Sec. 3. That it shall be the duty of every district attorney to whom the Secretary of Agriculture shall report any violation of this Act, or to whom any person, acting either on his own behalf or as the officer or agent of any State or Territory, the District of Columbia, or insular possession, shall present satisfactory evidence of any such violation, to cause proceedings to be commenced and prosecuted without delay for the fines and penalties in such case provided.

DEFINITIONS.

Sec. 4. That the term "drug," as used in this Act, shall include all medicines and preparations recognized in the United States Pharmacopœia for internal and external use; also any substance intended to be used for the cure, mitigation, or prevention of disease. The term "food," as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or domestic animals, whether simple, mixed, or compound.

ADULTERATIONS AND MISBRANDING.

Sec. 5. That for the purposes of this Act an article shall be deemed to be adulterated—

In case of drugs:

First. If, when a drug is sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality, o[illegible] by the test laid down in the United States [illegible] at the time of the investigation: Provided, That no drug shall be deemed to be adulterated under this provision if the standard of strength, quality, or purity be plainly stated upon the bottle, box, or other container thereof, although such standard may differ from that determined by the test laid down in the United States Pharmacopœia.

Second. If its strength or purity fall below the professed standard under which it is sold.

That such drug shall be deemed to be misbranded:

First. If it be an imitation of or offered for sale under the name of another article.

Second. If the package containing it or its label shall bear any statement regarding the ingredients or the substances contained therein, which statement shall be false or misleading in any particular, or if the same is falsely branded as to the State or Territory or place in which it is manufactured or produced.

In the case of confectionery an article shall be deemed to be adultered:

If it contain terra alba, barytes, talc, chrome yellow, or other mineral substances or poisonous colors or flavors, or other ingredients deleterious or detrimental to health.

In the case of food an article shall be deemed to be adulterated:

First. If any substance or substances has or have been mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength.

Second. If any substance or substances has or have been substituted wholly or in part for the article.

Third. If any valuable constituent of the article has been wholly or in part abstracted.

Fourth. If it contain any added poisonous or other ingredient which may render such article injurious to the health of the person consuming it: Provided, That goods intended for export shall not be deemed misbranded or adulterated when prepared and packed in accordance with specifications of the foreign purchaser, provided no substance is used that is in conflict with the laws of the country to which the goods are to be shipped, when such country, having laws upon the subject, does not prohibit such process.

Fifth. If it consists in whole or in part of a filthy, decomposed, or putrid animal or vegetable substance, or any portion of an animal unfit for food, whether manufactured, or not, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter.

An article of food shall be deemed to be misbranded:

First. If it be offered for sale under the distinctive name of another article: Provided, That the term "distinctive name" shall not be construed as applying to any article sold or offered for sale under a name that has come into general use to indicate the class or kind of the article if the name be accompanied on the same label or brand with a statement of the place where said article has been manufactured or produced.

Second. If it be mixed, colored, powdered, or stained in a manner whereby damage or inferiority is concealed, so that such product, when sold or offered for sale, shall deceive or tend to deceive the purchaser.

Third. If it be labeled or branded with intent so as to deceive or mislead the purchaser, or purport to be a foreign product when not so, or is an imitation, either in package or label, of another substance of a previously established name, or which has been trade-marked or patented.

Fourth. If the package containing it or its label shall bear any statement, design or device regarding the ingredients or the substances contained therein, which statement, design, or device shall be false or misleading in any particular, or if the same is falsely branded as to the State, Territory, or place in which it is manufactured or produced:

Provided, however, That an article of food which does not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated or misbranded in the following cases:

First. In the case of mixtures or componds which may be now or from time to time hereafter known as articles of food, under their own distinctive names, and not included in definition first of misbranded articles of food in this section.

Second. In the case of articles labeled, branded, or tagged so as to plainly indicate that they are mixtures, compounds, combinations, imitations, or blends: *Provided, That the same* shall be labeled, branded, or tagged so as to show the character and constituents thereof. And provided further, That nothing in this Act shall be construed as requiring or compelling proprietors or manufacturers of proprietary foods which contain no unwholesome added ingredients to disclose their trade formulas, except in so far as the provisions of this Act may require to secure freedom from adulteration or imitation: Provided further, That no dealer shall be convicted under the provisions of this Act when he can establish a guaranty signed by the wholesaler, jobber, manufacturer, or other party from whom he purchases such articles to the effect that the same is not adulterated or misbranded within the meaning of this Act, designating it: And provided further, That said guarantor or guarantors reside in the United States. Said guaranty, to afford protection, shall contain the name and address of the party or parties making the sale of such article to such dealer, and said party or parties shall be amenable to the prosecutions, fines, and other penalties which would attach, in due course, to the dealer under the provisions of this Act.

Sec. 6. That every person, company, or corporation who manufactures or produces and delivers for interstate or foreign shipment or transportation, or who receives from any State, Territory, or the District of Columbia, or insular possession or foreign country, other than the State, Territory, District of Columbia, or insular possession in which it is received, and any person, company, or corporation who sells or exposes for sale in any Territory, or the District of Columbia, or insular possession, any article of food or drug shall furnish, within business hours and upon tender and full payment of the selling price, a sample of such drug or article of food to any person duly authorized by the Secretary of Agriculture to receive the same, and in any Territory, or the District of Columbia, or insular possession, to any officer or agent of such Territory or District, respectively, charged with the inspection of food or drugs in such jurisdiction, and who shall apply to such manufacturer, producer, or person, company, or corporation selling or exposing for sale as aforesaid such drug or article of food for such sample in sufficient quantity for an analysis of any such article or articles in his possession.

Sec. 7. That any manufacturer, producer, or dealer who refuses to comply, upon demand, with the requirements of section six of this Act shall be guilty of a misdemeanor, and upon conviction shall be fined not exceeding one hundred dollars or imprisonment not exceeding one hundred days, or both. And any person found guilty of manufacturing or offering for sale, or selling, any adultered, impure, or misbranded article of food or drug in violation of the provisions of this Act shall be adjudged to pay, in addition to the penalties hereinbefore provided for, all the necessary costs and expenses incurred in inspecting and analyzing such adulterated articles which said person may have been found guilty of manufacturing, selling, or offering for sale.

Sec. 8. That any article of food or drug that is adulterated or misbranded within the meaning of this Act, and is being transported from one State to another for sale, or having been transported, remains unloaded, unsold, or in original unbroken packages, or if it be sold or offered for sale in the District of Columbia and the Territories of the United States, or if it be imported from a foreign country for sale, or if intended for export to a foreign country, shall be liable to be proceeded against in any district court of the United States within the district where the same is found and seized for confiscation by a process of libel for condemnation. And if such article is condemned as being adulterated or misbranded within the meaning of this Act the same shall be disposed of by destruction or sale, as the said court may direct, and the proceeds thereof, if sold, less the legal costs and charges, shall be paid into the *Treasury of the* United States, but such goods shall not be sold in any State contrary to the laws of that State: Provided, however, That upon the payment of the costs of such libel proceedings and the execution and delivery of a good and sufficient bond to the effect that such articles shall not be sold or otherwise disposed of contrary to the provisions of this Act, or the laws of any State, *Territory, or laws enacted for* the District of Columbia, the court may order direct that such articles be delivered to the owner thereof. The proceedings of such libel cases shall conform, as near as may be, to proceedings in admiralty, except that either party may demand trial by jury of any issue of fact joined in such case and all such proceedings shall be at the suit of and in the name of the United States.

Sec. 9. That this Act shall not be construed to interfere with commerce wholly internal in any State, nor with the exercise of their police powers by the several States: Provided further, That nothing in this Act shall be construed to interfere with legislation now in force, enacted either by Congress for the District of Columbia or by the Territorial legislatures for the several Territories, regulating commerce in adulterated foods and drugs within the District of Columbia and the several Territories, except wherein such legislation conflicts with the provisions herein.

Sec. 10. That the provisions of this Act shall not apply to common carriers, or their servants, agents, or employes.

Sec. 11. That this Act shall take effect and be in force from and after the first day of January, nineteen hundred and five.

Passed the House of Representatives January 19, 1904.

Bearing on the above we quote from two letters written by Senator Heyburn to Dr. Reed, chairman of the Committee on Medical Legislation of the American Medical Association.

United States Senate, Committee on Manufactures.

March 16, 1904.

. . . . I presume that you are familiar with both the House and Senate bills, known as the Hepburn bill and the McCumber bill, respectively. In our judgment, the Senate bill covers the question fully, and we hope to secure its passage at an early date. It has been fought by the patent-medicine trade, and also by the blenders of whisky, as well as by a number of other concerns desiring to avoid the exposition of their methods, which the bill would injure if enacted into law.

Letters from physicians commending and urging the passage of the bill will be of material assistance. The patent-medicine contingent and others opposed to the bill are inundating the members of the Senate with telegrams and letters, which would be well counteracted by expressions of opinion from physicians. In my judgment, the physicians next to the patients are most interested in the purity of medicines and foods.

(Signed) W. B. Heyburn.

March 18, 1904.

I have received many letters from physicians urging the passage of the Pure Food bill now pending before the United States Senate and reported by the committee of which I am chairman, but they all designate it by its House number—6295. The Senate committee have made some changes in the House bill, which, we think, are for the benefit of the measure. These changes are to be found embodied in the Senate bill, which was reported as a substitute for the House bill, a copy of which I hand you herewith. You will notice that the bill still bears the House number, but not the text of the House bill. The Senate bill drops out Sections 1 and 7 of the House bill, and avoids the creation of a new and expensive department. It also leaves out the provision of the House bill under which the Secretary of Agriculture should establish *standards*, and in lieu thereof makes the American Pharmacopeia the standard of purity, etc., as to everything within its scope, and provides in addition thereto, "also any substance to be used for the cure, mitigation or prevention of disease."

The committee is advised that the American Pharmacopeia has not been revised for about twelve years, and that it is *at most* only published every ten years. It is, therefore, apparent that the vast number of medicines, patented or otherwise, which come into existence and use between the periods of publication of the Pharmacopeia, should be included within the scope of the protection intended by the bill. The attention of the committee was called to many of these patent medicines and other "catchpennies," and it was deemed by the Senate committee necessary to have some general principle that would include the determination of the articles not included within the Pharmacopeia, by such rules as the courts may establish, and the courts will undoubtedly follow as nearly as possible such standards as the Pharmacopeia will adopt, if they adopt any for this class of medicines. You are *undoubtedly advised* of the fact that between the last two publications of the Pharmacopeia some thousands of articles came into use, which are not included in the last publication, and were not included in the previous one, and it is fair to assume that the increase has been quite as marked since the last publication, and to stop where the retail drug men have asked us to stop, with the American Pharmacopeia, would leave the door wide open to the deleterious medicines and nostrums that have come into use since its adoption.

I write you this fully in order that you may give me the benefit of your suggestions as to the provisions in the Senate bill not contained in the House bill. The majority of the committee is in favor of the additional restrictions contained in the Senate bill, and unless very good reason is shown for it will insist on it standing. The strongest opposition is made on behalf of the patent-medicine people speaking through the retail druggists.

I would strongly urge on you that you communicate with as many physicians in the United States and as many medical organizations in United States and as many medical organizations as possible to be reached, that they may thoroughly understand that if they will be kind enough to express their opinion to me in favor of the Senate bill reported as a substitute for the House bill, it will materially aid us in meeting the oposition to the bill.

You will find that the strongest opposition to the Senate bill is from patent-medicine people and retail druggists. I solicit your earnest co-operation in this matter. Of course, I need not assure you that I shall do everything in my power to secure the passage of the bill as reported by the Senate committee.

(Signed) W. B. Heyburn.

The Antiquity of Castor Oil.—According to the *Medical Age*, Professor Larit of France says that some of the seeds of the *castor oil plant found in Egyptian tombs at* Thebes could not be less than 3,000 years old, and were perfectly preserved, the oil which they contained being simply rancid. Larit has translated an ancient papyrus, which goes to show that the uses to which the ancient Egyptian put the oil were much the same as those of the present day.

Cocain in Postpartum Hemorrhage.—Dr. C. Fox of Caerphilly writes to the *British Med. Jour.* as follows: I was called suddenly to a case of postpartum hemorrhage. I could see at a glance the patient was in an exceedingly grave condition. Uterus on examination, flaccid; hemorrhage profuse, the countenance portraying approaching death. Having no ergotin, I bethought me of a solution of cocain hydrochlorate I happened to have in my bag. I immediately injected a quantity equal to 1½ grains, and in the course of two minutes at most the uterus had contracted, the hemorrhage had ceased, and the facial expression completely altered. The patient then spoke in her usual voice and said she felt "quite well." She made an uninterrupted recovery. I should be very glad to hear if any of your numerous readers ever tried cocain in a similar case. I have not heard of it being so used, though I have often inquired. To me the effect was marvelous.

What Makes a Physician.—The skill of a physician is in part similar to that of any other man of science. Primarily he should have a mind of detail and exact thinking. The method of exclusion, "It can not be anything else, so it must be typhoid," is the sign of vagueness, and has diminished with the progress of the laboratory spirit. The able diagnostician recognizes each disease, not by loose, obvious symptoms, but by a variety of exact details, often discoverable only on analysis, and peculiar to that disease. This exact mind for detail makes the physician on the side of diagnosis. When it comes to acting on his understanding, to removing a condition which he understands, other qualities become requisite. No profession in our day has made such progress as the medical, counting surgery as part of it; and its unexampled improvement is part of our progress in science, the field of thought in which the nineteenth century was most notable. In many professions there has been no progress at all, certainly not in law or in the pulpit.—*Collier's*.

The Recognition of Osteopaths.—Much as we may wish to ignore the existence of the osteopaths as a school of physicians, they are securing followers in such numbers and are demanding recognition from the legislative bodies with such positiveness that they have gained firm footing in spite of our protests. We have contented ourselves with passing resolutions in our medical societies while they have labored night and day with greatest earnestness. We have merely "referred the matter to our legislative committees," while they have made pilgrimages to state capitals and have bearded the legislators in their dens. In Arkansas, Oklahoma, Missouri, Michigan and Minnesota the osteopaths have been accorded state recognition and select their own examiners; in Alabama this was prevented only by the vote of the lieutenant governor (who chanced to be a doctor), after the bill had passed the House and had gained half the votes of the Senate. In Kentucky and Mississippi the osteopaths are putting up a bitter and determined fight, and stand a good chance of securing favorable laws in the next sessions of the legislatures. They are working day and night, summer and winter, week days and Sundays, while the medical profession of the various states pass resolutions or refer to committees and then sink back into their apathetic state. In Illinois, we are told, the osteopaths will demand recognition again in 1905. The systematic work is now on. Their opposing forces, the medical profession of the state, is doing little in preparation for the fray. Twice in the past have these disciples of the sage of Kirksville succeeded in passing bills through both houses of the Illinois legislature. Laws recognizing osteopaths in Illinois would be on our statutes to-day had the action of the medical profession of the state been depended on to check them. In the administration of the late Governor John R. Tanner one bill passed both houses and was promptly vetoed by the governor, though far more pressure was brought to bear on him to sign the bill by the osteopaths than to veto by the medical profession. The last osteopathic bill was killed only by the vigorous veto of Governor Richard Yates. The time may come when the state of Illinois will not have governors who are inclined to protect the medical profession so vigorously. A governor may come who will prefer to listen to the emphatic voices of hundreds of determined osteopaths rather than to the whispered protests of a handful of doctors. Then Illinois will pass favorable osteopathic bills. It is not the osteopath alone who is concerned in this matter. The establishment of a precedent of recognizing all of the mongrel cults, one of which is being born each month, will result in the establishment of a recognized medical fraternity which will be no credit to the state and which will be prejudicial to the interests of every reputable medical man in the state. It is not fair to expect that state authorities will close their ears to the pleas of thousands of voters who demand recognition of the osteopaths and the other cults when the medical profession manifests no interest in their own behalf. It is the duty of the legislators and of the governor to serve most of the people, and there can be no chosen few who will be given favoritism as a matter of course without even the form of asking.—*Chicago Clinic and Pure Water Journal.*

COMING EXAMINATIONS.

Arizona Board of Medical Examiners, Phoenix, April 4 Secretary, Wm. Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, Salt Lake City, April 4. Secretary, R. W. Fisher, M.D., Salt Lake City.

Board of Medical Examiners of Montana, Helena, April 5. Secretary, Wm. C. Riddell, M.D., Helena.

North Dakota State Board of Medical Examiners, Grand Forks, April 5. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of California, City Hall, San Francisco, April 5. Secretary, Geo. G. Gere, San Francisco.

Idaho State Board of Medical Examiners, Boise, April 6. Secretary, R. L. Nourse, M.D., Hailey.

Minnesota State Board of Medical Examiners, State Capitol Building, St. Paul, April 5-7. Secretary, C. J. Ringnell, M.D., Minneapolis.

Tennessee State Board of Medical Examiners, Memphis, Nashville and Knoxville, April 6-7. Secretary T. J. Happel, M.D., Trenton.

Illinois State Board of Health, Chicago, April 6-8; April 25-27, and East St. Louis, May 4-6. Secretary, J. A. Egan, Springfield.

Rhode Island State Board of Health, State House, Providence, April 7-8. Secretary, Gardner T. Swarts, M.D., Providence.

State Medical Board of the Arkansas Medical Society, Little Rock, April 12. Secretary, J. P. Runyan, M.D., Little Rock.

Missouri State Board of Health, Kansas City, April 12-14. Secretary, W. F. Morrow, M.D., Kansas City.

West Virginia State Board of Health. Clarksburg, April 12-14. Secretary, Hugh A. Barbee, M.D., Point Pleasant.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Rutland, April 13-14. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, April 14. Secretary, Wm. C. Woodward, M.D.

Board of Medical Examiners for the State of Texas, Austin, April 21-23. Secretary, M. M. Smith, M.D., Austin.

State Board of Medical Examiners of Iowa, April 14-15 at Keokuk, April 20-21 at Des Moines. Secretary, J. F. Kennedy, M.D, Des Moines.

Nebraska State Board of Health, Lincoln, April 21-23. Secretary, Geo. H. Brash, M.D., Beatrice.

New Mexico Report.—Dr. B. D. Black, Las Vegas, secretary of the New Mexico Board of Health, reports that at the partly oral and partly written examination held at Santa Fe, December 7, 1903, 70 questions were asked on 7 subjects, and a percentage of 65 was required. Half of the four applicants passed.

ATLANTIC CITY HOTELS.

A List of the Hotels and Prices—Ample Accommodation for All.

Atlantic City has about 1,200 hotels and boarding houses. Out of these the committee has selected the following houses, with their rates appended, which they can recommend. Comfortable board may be obtained in Atlantic City from $1 per day upward. The minimum rates apply to single rooms without baths, while the per capita rate per day for double rooms in most cases can be slightly reduced when two occupy the same room. For those wishing accommodations on the European plan, the Dunlop and Young's Hotel are exclusively European; *the Grand Atlantic, the Wiltshire, the Garden, the Islesworth, and the Rudolf, furnish accommodations on either European or American plans. The prices given below cover the American plan, except those referring to the Dunlop and Young's Hotel.*

HOTELS.	RATES PER DAY ON AMERICAN PLAN.		
Bouvier	$1.50	and up.	
Roxborough	1.50	to	$2.50
Revere	2.00	to	2.50
Altamont Craig Hall	2.00	to	3.00
Archdale	2.00	and up.	
Belmont	2.00	and up.	
Berkshire Inn	2.00	to	3.00
Chester Inn	2.00	to	2.50
Dunlop, $2.00 to $3.00, European exclusively.			
Young's Hotel, $2.00 to $3.00, European exclusively.			
New Hygeia	2.00	to	3.00
Albermarle	2.00	to	3.50
Arlington	2.00	to	3.50
Holmhurst	2.00	to	4.00
Champlain	2.00	to	4.00
Kenilworth Inn	2.00	to	4.00
Hotel Majestic	2.00	to	4.00
Hotel Boscobel	2.00	to	6.00
Chatham	2.50	to	3.00
Glaslyn,	2.50	to	3.00
Hotel New England	2.50	to	3.00
Ponce de Leon	2.50		
Wiltshire (also European)	2.50	and up.	
Hotel Imperial	2.50	to	3.50
Hotel Shoreham	2.50	to	3.50
Loraine	2.50	to	3.50
Rittenhouse	2.50	to	4.00
Grand Atlantic (also European)	2.50	to	5.00
Raleigh	3.00		
Hotel Gladstone	3.00	to	5.00
Hotel Savoy	3.00	to	5.00
Hotel Strand	3.00	to	5.00
Haddon Hall	3.00	to	7.00
Islesworth (also European)	3.00	to	8.00
Shelburne	3.00	to	8.00
Seaside	3.50	to	4.00
Rudolf (also European)	3.50	to	5.00
Garden	3.50	to	6.00
Hotel Dennis	3.50	to	6.00
Royal Palace	3.50	to	6.50
Hotel Windsor	3.50	to	7.00
Hotel Chelsea	4.00	and up.	
St. Charles	4.00	and up.	
Hotel Traymore,	4.00	to	8.00
Hotel Brighton	4.00	to	10.00
Marlborough House	4.00	to	10.00

In order to get good accommodations engagements for rooms should be made without delay. The committee will be glad to furnish any information desired, and will be pleased to engage quarters at the various hotels, or physicians may write to the hotel direct.

WM. EDGAR DARNALL,
Chairman Hotel Committee.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending March 19, 1904:

Raymond, Thos. U., surgeon, on being relieved from duty at Jefferson Barracks, Mo., by Major Wm. B. Banister, surgeon, will proceed to St. Louis for special duty at the Louisiana Purchase Exposition, with a view to exercising supervision over the sanitary conditions on the grounds.

De Loffre, Samuel M., asst.-surgeon, granted fourteen days' leave April 1, with permission to apply for seven days' extension.

Gosman, Geo. H. R., asst.-surgeon, relieved from duty at Fort Duchesne, Utah, and ordered to Camp Geo. H. Thomas, Ga., for duty.

Siler, Jos. F., asst.-surgeon, granted fourteen days' leave.

Navy Changes.

Changes in the medical corps of the Navy, week of March 26:

Green, E. H., medical inspector, detached from the *Kentucky* and ordered to the *New Orleans*.

Fitzsimons, P., medical director, to Navy Yard, Washington, D. C.

Bishop, L. W., asst.-surgeon, detached from the *Annapolis* and ordered to the Naval Hospital, Mare Island, Cal., for treatment.

Munson, F. M., asst.-surgeon, detached from the *Frolic* and ordered to the Naval Station, Pollok, P. I.

Traynor, J. P., asst.-surgeon, detached from the Naval Station, Pollok, P. I., and ordered to the *Frolic*.

McClanahan, R. K., asst.-surgeon, ordered home and granted sick leave for three months.

Ledbetter, R. E., asst.-surgeon, detached from the *Newark* and ordered home to wait orders.

Pryor, J. C., P. A. surgeon, detached from the *Bancroft* and ordered home to wait orders.

Plummer, R. W., P. A. surgeon, from the *Maine* to the *Bancroft*.

McDonnold, P. E, asst.-surgeon, detached from the *Olympia* and ordered home to wait orders.

The following assistant surgeons are detached from the U. S. Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the following positions, respectively:

Abeken, F. G., to Training Station, San Francisco.
Smith, W. B., to the *Olympia*.
Kohlhase, O., to the *New York*.
Randall, J. A., to the *Maine*.
Rennie, W. H., Hoen, W. S., Verner, W. W., Grieve, C. C, DeBruler, J. P., Dean, F. W. S., Dykes, J. R., and Geiger, A. J., to the Asiatic Station, via the *Solace*.
Scott, S. L., to the *Massachusetts*.
Dorsey, B. H., to the *Illinois*.
McLean, A. D., to the *Alabama*.
Manchester, J. D., to the *Columbia*.
Rider, C. E., to the *Missouri*.
Pugh, Jr., W. S., to the *Prairie*.
Pease, T. N., to the *Hartford*.
Reeves, I. S. K., to the *Minneapolis*.
Sutton, R. L., to the Bureau of Medicine and Surgery, Navy Department.
Ely, C. F., Dessez, P. T., to the Naval Academy, Annapolis
Woodward, J. S., to Indian Head.
Riggs, R. E., to the *Newark*.
Rossiter, P. S, to Baltimore Recruiting Station.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended March 24, 1904:

Carter, H. R., surgeon, to report at Bureau for special temporary duty.

Peckham, C. T., surgeon, and Smith, A. C., P. A. surgeon, detailed for duty on Revenue-Cutter Service retiring board at New York.

Rosenau, M. J., P. A. surgeon, to proceed to Boston, Albany and New York, for special temporary duty.

McMullen, John, P. A. surgeon, Bureau order of Feb. 20, 1904, directing him to report to chief quarantine officer of Hawaii for duty, revoked.

Foster, M. H., P. A. surgeon, granted leave of absence for ten days from March 30.

Lumsden, L. L., P. A. surgeon, relieved from duty at New Orleans and directed to proceed to Vera Cruz, Mexico, for duty in office of the United States Consul.

King, W. W., asst.-surgeon, granted leave of absence for six days from March 18.

Goldberger, Joseph, asst.-surgeon, relieved from duty in Hygienic Laboratory and directed to proceed to Tampico, Mexico, for duty in office of the United States Consul.

Roberts, Norman, asst.-surgeon, relieved from duty at San Diego, Cal., and directed to proceed to New Orleans, and report to medical officer in command for duty and assignment to quarters.

Salmon, T. W., asst.-surgeon, relieved from duty at Philadelphia and directed to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters.

Bakes, E. C., A. A. surgeon, granted leave of absence for three days from March 19, 1904, under Paragraph 191 of the Regulations.

Mackall, B. McV., A. A. surgeon, granted leave of absence for fifteen days from March 31.

Tidd, R. M., A. A. surgeon, granted leave of absence for fourteen days from April 1.

BOARD CONVENED.

Board convened at Washington, D. C., March 25, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended March 25, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, March 6-13, 4 cases, 4 deaths.
Delaware: Wilmington, March 12-19, 1 death.
District of Columbia: Washington, March 12-19, 1 case.
Florida: Jacksonville, March 12-19, 2 cases.
Illinois: March 12-19, Chicago, 5 cases; Danville, 1 case; Galesburg, 3 cases.
Kentucky: Covington, March 12-19, 1 case.
Louisiana: New Orleans, March 5-19, 3 cases, 2 imported.
Maine: Bradley, March 18, 2 cases; Madawaska region, March 12-19, 7 cases.
Maryland: Baltimore, March 12-19, 1 case.
Massachusetts: March 12-19, Fall River, 1 case; Lowell, 1 case.
Michigan: March 12-19, Detroit, 1 case; Grand Rapids, 1 case.
Missouri: St. Louis, March 12-19, 6 cases.
New Jersey: March 12-19, Camden, 6 cases, 1 death; Trenton, 1 case.
New York: March 12-19, Buffalo, 1 case; New York, 1 death; Niagara Falls, 4 cases.
Ohio: Cleveland, March 11-18, 3 cases, 1 death; Dayton, March 12-19, 8 cases, 1 death; Hamilton, Jan. 30-Feb. 6, 1 case.
Pennsylvania: March 12-19, Allentown, 3 cases; Altoona, 1 death; Philadelphia, 30 cases, 7 deaths; Pittsburg, 1 case, 1 death; Williamsport. 1 case; Carbondale, March 14-21, 2 cases.
Tennessee: March 12-19, Memphis, 21 cases; Nashville, 13 cases.
Wisconsin: Milwaukee, March 12-19, 6 cases.

SMALLPOX—FOREIGN.

Austria: Feb. 27-March 5, Prague, 4 cases; Trieste, 1 case.
Belgium: Antwerp, Feb. 27-March 5, 7 cases, 3 deaths; Brussels, Feb. 20-March 5, 2 deaths.
Brazil: Bahia, Feb. 13-20, 1 death; Pernambuco, Feb. 1-15, 17 deaths; Rio de Janeiro, Feb. 7-14, 128 cases, 67 deaths.
China: Feb. 3-10, Shanghai, 16 cases, Tientsin, reported.
France: Lyons, Feb. 20-27, 1 death.
Great Britain: Feb. 27-March 5, Edinburgh, 6 cases, 2 deaths; London, 13 cases; Manchester, 1 case; Nottingham, 14 cases, 1 death; South Shields, 1 case; Glasgow, March 4-11, 19 cases, 1 death: Sheffield, Feb. 20-27, 4 cases.
India: Bombay, Feb. 16-23, 20 deaths; Karachi, Feb. 14-21, 4 cases, 2 deaths.
Java: Batavia, Feb. 6-13, 19 cases, 9 deaths.
Mexico: City of Mexico, Feb. 28-March 6, 9 cases, 5 deaths; Vera Cruz, March 5-12, 1 case, 1 death.
Netherlands: Amsterdam, March 5-12, 1 case, 1 death.
Russia: Moscow, Feb. 17-24, 13 cases, 1 death; Odessa, Feb. 27-March 5, 1 case; Warsaw, Feb. 28 March 6, 11 deaths.
Spain: Barcelona, March 1-10, 9 deaths; Santander, Feb. 29-March 7, 3 cases.
Turkey: Constantinople, Feb. 28-March 6, 5 deaths.

SMALLPOX—INSULAR.

Philippine Islands: Antimonan, Feb. 5-12, present; Cebu, Jan. 1-31, 5 cases, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 7-28, 15 cases, 4 deaths.
Mexico: March 6-12, Merida, 1 case, 2 deaths; Tehuantepec, 4 cases; Vera Cruz, March 5-12, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Jan. 30-Feb. 6, Manila, 2 cases, 2 deaths; Provinces, 53 cases, 35 deaths.

CHOLERA—FOREIGN.

Turkey in Asia: Basra, Feb. 6-12, 6 cases, 3 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Jan. 30-Feb. 6, 3 cases, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Para, Feb. 15, 2 cases; Rio de Janeiro, Feb. 7-28, 13 cases, 6 deaths.
India: Bombay, Feb. 16-23, 718 deaths; Karachi, Feb. 14-21, 97 cases, 74 deaths.

Medical Organization.

Arkansas.

Searcy County Medical Society.—On March 2, physicians of the county assembled at Marshall and organized a county society, with a charter membership of 7, and the following officers: Dr. William F. Rogers, St. Joe, president; Dr. Perry G. Hays, Blanco, vice-president; Dr. Samuel G. Daniel, Marshall, secretary; Dr. J. Oliver Cotton, Leslie, treasurer, and Dr. James A. Henley, St. Joe, librarian.

Louisiana.

Bienville Parish Medical Society.—Physicians of the parish met at Bienville, March 17, and organized a medical society with the following officers: Dr. Francis M. Thornhill, Arcadia, president; Dr. Andrew J. Pennington, Gibsland, vice-president; and Dr. Oliver O. Hamner, Bienville, secretary and treasurer.

Missouri.

Maries County Medical Society.—This society has been organized on the standard plan with the following officers: Dr. Otto C. Fritts, Belle, president; Dr. William E. Johnson, Lois, and Dr. Otto N. Schudde, Vienna, secretary and treasurer.

Ohio.

Trumbull County Medical Society.—Dr. Thomas C. Martin, Cleveland, met with physicians of the county at Warren, March 19, and after setting forth the benefits to be derived from standard organization, assisted in the reorganization of the society on that plan. The officers of the temporary organization are: Dr. Frederick K. Smith, Warren, president; Dr. Curtis C. Williams, Niles, secretary, and Drs. Smith, Williams and Delbert E. Hoover, Warren, committee on constitution, by-laws and permanent organization.

Texas.

Palo Pinto County Medical Association.—At a meeting of physicians of the county held at Mineral Wells, March 14, organization was effected on the standard plan, and the following officers were elected: Dr. John M. Luttrell, Mineral Wells, president; Dr. Robert H. Smith, Palo Pinto, vice-president; Dr. Robert L. Yeager, Mineral Wells, secretary and treasurer; Dr. Horatio B. Withers, Mineral Wells, censor, and Dr. Benjamin R. Beeler, Mineral Wells, delegate to the state association.

Wisconsin.

Inter-County (Buffalo and Pepin) Medical Society.—A meeting of physicians of the two counties was held in Durand, March 17, at which a medical society was organized with seven members and the following officers: Dr. Milton B. Axtell, Pepin, president; Dr. Jacob S. Tenney, Alma, vice-president; Dr. Philip B. Amundson, Mondovi, secretary, and Dr. Edmund C. Jacobs, Durand, treasurer.

Society Proceedings.

COMING MEETINGS.

Medical Association of the District of Columbia, Washington, April 5.
Tennessee State Medical Association, Chattanooga, April 12.
South Carolina Medical Association, Darlington, April 13.
Medical Association of the State of Alabama, Mobile, April 19.
Medical Society of the State of California, Paso Robles, April 19-21.
Florida Medical Association, Live Oak, April 20.
Medical Association of Georgia, Macon, April 20.
Mississippi State Medical Association, Jackson, April 20.
Texas State Medical Association, Austin, April 26.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 26-28.
Arizona Medical Association, Tucson, April 27-28.

AMERICAN SOCIETY OF TROPICAL MEDICINE.

First Annual Meeting, held at the College of Physicians, Philadelphia, March 21, 1904.

Leprosy and Dysentery Specimens.

Dr. W. M. L. Coplin presented specimens of hands showing the lesions of anesthetic leprosy, one of which showed a nerve with the leprous nodules. He also exhibited specimens showing the lesions of amebic and bacillary dysentery. In one of the cases the *Ameba coli* was demonstrated during life and the Shiga bacillus was obtained from the intestine postmortem. He also showed specimens of hepatic abscesses following both amebic dysentery and bacillary dysentery. He also showed a duodenum with the *Uncinaria duodenale* in situ.

Dr. Judson Daland said that the Japanese physicians, who see a number of cases of uncinariasis, believe that the cases of pernicious anemia that seem to arise from infection with that parasite are due to the hemorrhages from the intestinal wall following the death and removal of the worm, which attaches itself intimately to the mucosa.

Leishman-Donovan Bodies.

Dr. Joseph McFarland, through the kindness of Sir Patrick Manson, exhibited some slides showing the Leishman-Donovan parasites. These were first described by Maj. W. B. Leishman in May, 1903, who found them in the blood of patients suffering from dum-dum fever, which was formerly supposed to be of a malarial nature, presented, when admitted to Netley, an extreme degree of cachexia, an irregular, remittent type of fever, grave anemia, progressive muscular atrophy and great enlargement of the spleen. Digestive and bowel disturbances were frequent. In none of the cases admitted to Netley were malarial parasites found in the blood, nor was there any record of these organisms having been found at an earlier stage of the disease. On making smear preparations from the splenic pulp from one of the cases, Leishman found large numbers of small, round or oval bodies unlike anything previously seen or described. On staining with Romanowsky's method they were found to possess a quantity of chromatin of a definite and regular shape, which differentiated them from blood plates or possible nuclear detritus. The chromatin appeared in the form of a circular mass or ring with a smaller chromatin mass in the form of a short rod applied at a tangent or perpendicularly to it. Later, Donovan reported finding similar bodies in smears taken postmortem from the enlarged spleens of natives who had died of what was supposed to be chronic malaria. Still later he found similar bodies in the smears made after a splenic puncture during life from a boy aged 12 years, who had no malarial parasites in his peripheral blood. The bodies described by Donovan were afterward examined by Ross, who determined that they were in every way identical with those discovered by Leishman. Up to Nov. 5, 1903, Donovan found the bodies in 16 cases after puncture of the spleen and the liver during life. In January, 1904, Manson and Low tapped the enlarged spleen of a man from Darjeeling and found a large number of the parasites. The bodies have not been found in the circulating blood nor have they been found in the feces or the urine of the host. An attempt to cultivate the parasites on blood agar failed.

Hymenolepis Nana.

Dr. Allen J. Smith, in his own name and that of Dr. L. E. Magnenat of Amarillo, Texas, exhibited specimens of the adult *Hymenolepis nana* and its ova. This worm was first encountered by Bilharz as a human parasite in Cairo, in 1851; and since then it has been mainly found in the same general locality, but especially in Italy. Instances from central Europe, from France, England, South America and elsewhere are also on record. In the United States, Spooner announced a case in 1872, from Philadelphia, and his specimens are deposited in the collection of the College of Physicians. The case has, however, been placed in doubt by Leuckhart and others, and Dr. Smith knows of no effort to verify or positively contradict the question which has arisen. This single case of Spooner being omitted as possibly being *Tenia flavopunctata*, the first instance of the parasite in the United States was found in Galveston, Texas, in 1892, by Moore and Elliott in a railway laborer applying for relief of a troublesome and persistent diarrhea in the St. Mary's Infirmary. The specimens recovered from the stools were offered the writer for identification. Following this case, Stiles, in his systematic examination of intestinal dejecta in Washington and some of the southern states, found 4 instances of the same parasite; and following his efforts the widespread study of stools for parasites led, before the announcement of the material here presented, to the recognition of perhaps a dozen more cases in this country. So far as Dr. Smith now is aware, the cases from which this material was obtained, 3 children of one family in Amarillo, Texas, are Nos. 17, 18 and 19 in the American literature. The cases were discovered in the spring of 1903 by Dr. L. E. Magnenat, a practitioner of medicine at Amarillo, who furnished the specimens that Dr. Smith showed. All the patients were young, badly nourished and neurotic children, and the discovery of the ova in the stools followed the search for the ova of uncinaria, which Dr. Magnenat suspected because of the anemia and general undernutrition. The energetic use of anthelmintics was followed by the recovery from the stools of between 500 and 1,000 specimens. At the time of last information the persistence of ova in the stools indicates that the parasites have not been entirely dislodged." The worm has been regarded by Grassi and others as identical with

Hymenolepis murina of rats, although others have denied this point (Moriez). Grassi has shown that it is possible to infect young white rats (from 1 to 4 months old) directly by feeding ripe links of *Hymenolepis murina* without an intermediate host (although probably ordinarily an intermediate host of some arthropod, as fleas or lice, harbor the cysticercoid of the worm). Dr. Smith has endeavored, by feeding human stools containing eggs of *H. nana* over a period of 8 weeks, to infect white rats of selected age, but has systematically failed. Thus far he has not been in a position to infect by means of an intermediate host. The specimens when fully developed are usually 10 to 15 mm. long and ½ to ⅞ mm. wide at the widest part. The head is subspherical, a little over ¼ mm. in diameter, provided with a retractile rostellum, armed with a single row of 24 to 30 hooklets; and with 4 rounded suckers, 90 to 105 microns in diameter. The neck is long, gradually merging with the head. The first segments are very short and not well defined, the succeeding ones gradually growing broader and longer until, when complete, they measure 0.14 to 0.30 mm. in length and 0.4 to 0.8 or 0.9 mm. in width; the last ones a little narrower and longer. The eggs are round or slightly oval, double walled and measure from 40 to 45 microns to 50 or 55 microns. The contained embryo measures from 20 to 24 microns. Each embryo is provided with 6 hooklets. In the space between the inner and the outer wall are seen several small thread-like bodies of unknown importance. There is a small papilla at each end of the embryophore.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Thomas H. Fenton; vice-presidents, Drs. J. J. Kinyoun and James M. Anders; treasurer, Dr. Alfred Hand; secretary, Dr. Joseph McFarland; assistant secretary, Dr. John M. Swan; councilors, Drs. Roland G. Curtin, Judson Daland, John V. Shoemaker, Allen J. Smith and W. M. L. Coplin.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting of the Section on Pathology, held March 15, 1904.

The Serum Test for Blood.

Dr. Herbert U. Williams demonstrated the serum test for blood as a means of detecting human blood in medicolegal cases. The biologic or precipitin reaction was discovered incidental to experimental work in animals on artificial immunity in infectious diseases. When an animal receives injections of foreign material into the blood, it develops a condition comparable to that of immunity. The blood serum of such an animal requires three properties: (1) That of destroying or disintegrating cells as in immunizing animals for bacteria; (2) the serum develops the property of agglutinating the same cell as the agglutinating reaction in typhoid fever (Widal serum reaction) or the agglutination test for *Bacillus pyocyaneus*, streptococci, pneumococci, etc.; (3) when blood is injected into an animal it can agglutinate the serum of animals of the same species and acquire the property of inducing a precipitate. So that if the egg albumin of a hen is injected into a rabbit the serum of the rabbit will form a precipitate with the egg albumin of the animal from which the egg is derived or its serum.

This principle has been applied to the blood of various animals, including that of man. Uhlenhuth first showed it, then Nuttall also. Nuttall examined the blood of a large number of animals, including man, and got the reaction, finding it negative in only the orang outang, chimpanzee and gorilla. A student of Nuttall also applied the blood test on blood stains obtained from Scotland Yard detective office, such as on knives, leather, etc., and though the stains were of all ages he could make a positive test for human blood from the oldest stains.

The method is briefly as follows: Human blood is obtained from any source, placenta, fetus, etc., and 30 to 60 c.c. are injected into the rabbit at intervals of 3 days to a week, over a period of two to three months, injecting 5 to 10 c.c. at a time. One to two weeks after the last injection the blood of the rabbit acquires its greatest potency. The rabbit is then bled from the carotid artery into a clean flask and the serum separated.

The blood clot or suspected blood stain is dissolved in distilled water and then mixed with double normal salt solution. This dilution of distilled water and salt solution and blood should be in the proportion of 1-50 to 1-100. To this solution the serum of the blood from the rabbit is added in a test tube, and if the test is positive a precipitate is formed.

Dr. Williams referred to the detection of human blood by measuring the red corpuscles. The diameter of the red corpuscle of man is 1/3200 of an inch, and of the dog and the rabbit nearly the same size, about 1/4000 of an inch. This method may be at fault, for it is known that the red blood corpuscles vary greatly in size in anemias, especially pernicious anemia.

Dr. Williams used the precipitin test. He used serum of rabbits inoculated with blood from a fetus and from a placenta and with pleuritic fluid, and in the fourth rabbit beef blood was used. The control experiments were made with the blood of pig, rabbit, horse, guinea-pig, rat, cat and sheep. The precipitin test was obtained with human and beef blood best; it also was obtained from the horse's blood and from that of a dog.

Dr. Williams states that the procedure is by no means simple, as it requires two to three months to get the rabbit's serum fortified so that it can be used. This makes it unpractical in medicolegal cases in which the time given for such an investigation is often short. He was very careful in his technic, but from the behavior of the reaction in his experiments thus far he does not believe this serum test for human blood is safe, for it is inconstant.

Case Reports.

Dr. DeLancey Rochester showed an aneurism of the arch of the aorta, with calcareous deposit on the aortic valve. It was from a hard-working farmer between 50 and 60 years of age. There was no history of any illness which might result in an aneurism. There were few subjective symptoms of aneurism and no pressure symptoms. The manner of death was unknown.

Dr. Albert E. Woehnert demonstrated slides from a case of pernicious anemia with blood crisis.

Dr. Charles A. Bentz demonstrated a male and a female *Anchylostomum duodenale* and the eggs.

Dr. William Mosher spoke of his experiences with the purinometer. It is an instrument to detect the amount of purin bodies excreted in the urine. The amount excreted is dependent on the amount of nitrogenous material ingested and also on the metabolism of the body.

Dr. Carrol Roberts reported a case of aortic stenosis in a young woman suffering from tertiary syphilis.

RHODE ISLAND MEDICAL SOCIETY.

Business Meeting, held in Providence, March 3, 1904.

The President, Dr. William R. White, in the Chair.

The secretary, Dr. Stephen A. Welch, reported the membership to be 303, of whom 275 were active members.

The treasurer, Dr. George S. Mathews, reported a cash balance for the year of $621.62.

Officers Elected.

The following were elected officers for the ensuing year: President, Dr. William R. White, Providence; vice-presidents, Drs. Christopher F. Barker, Newport, and Charles V. Chapin, Providence; recording secretary, Dr. Stephen A. Welch, Providence; corresponding secretary, Dr. Herbert Terry, Providence; treasurer, Dr. George S. Mathews, Providence; delegate to the House of Delegates of the American Medical Association, Dr. John Champlin, Westerly; alternate, Dr. F. T. Rogers.

Constitution Revised.

The society unanimously voted to accept the revision of the constitution and by-laws which was drawn on the lines proposed by the American Medical Association. This revision has been in charge of a committee consisting of Drs. John

Champlin, F. T. Rogers, William R. White and George F. Keene.

Prize Essay Contest.

President White announced a prize of $500, offered by a member of the society for an essay by any member of the medical profession on the subject, "Postoperative Phlebitis." Every competitor for this prize is expected to forward to the president, Dr. William R. White, 7 Greene Street, Providence, R. I., on or before Feb. 1, 1905, a copy of his dissertation, legibly written, preferably in type and suitably bound, so as to be easily handled. The writer's name and address must be enclosed in a sealed envelope bearing on the outside a motto corresponding with one on the accompanying dissertation. Any clew given by the dissertation or any action on the part of the author which may reveal his name before the award of the prize will disqualify him. In case no dissertation is considered sufficiently meritorious, no award will be made. A high value will be placed on original work. Letters accompanying the unsuccessful dissertations will be destroyed unopened and the dissertation may be procured by their respective authors if application be made within three months after the announcement of the award.

Papers Read.

Dr. Herbert Terry read a paper on "Tumors of the Bladder," Dr. W. Louis Chapman one on "Postoperative Pneumonia with Experiments on Its Pathogenesy," and Dr. William F. Gleason one on the "Care of the Feeble-Minded."

Care of Feeble-Minded Children.

The society then passed the following resolution:

Whereas, It is the sense of this meeting that the care and training of the feeble minded are the concern of the state and should be pursued as an integral part of our system of public education and not as a charity; and

Whereas, It is sound public policy as well as to the advantage of the afflicted that such education for Rhode Island children should be provided by an institution in this state; therefore, be it

Resolved, That the legislative committee of this society be requested to present to the consideration of the honorable general assembly an adequate plan for putting into effect the education of feeble-minded children through the establishment by the state of a suitable home and school.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Laxative in Pregnant Women.

The following combination is recommended by Lutaud in *Jour. de Med. Interne*, as a laxative to relieve the constipation of pregnant women:

℞.	Olei ricini	℥i	30
	Syr. rhei	ʒvi	24
	Alcoholis	℥ss	15
	Ol. menth. pip.	ʒss	2

M. Sig.: At one dose.

Gastric Ulcer.

In the treatment of gastric ulcer, Hayden, in *Ther. Gaz.*, recommends that the patient be put to bed and given only a small amount of food, consisting of a quarter of a glass of milk every two hours, this to constitute the diet for four days.

Enemas are recommended three times a day, consisting of the following:

℞.	Dry peptones	℥i	30
	Yolk of two eggs		
	Aquæ (warm)	℥vii	200

M. Sig.: To be introduced into the bowel after a cleansing enema.

The quantity of milk may be increased to half a glass every two hours; on the eighth day to three-quarters of a glass, and on the twelfth day to a full glass, but not to exceed three quarts in the twenty-four hours. After twenty days, if vomiting does not take place and the milk is digested well, the quantity may be diminished and solid food given progressively as follows: Milk soup three times a day; soft boiled eggs, broth, broth with the yellow of an egg, meat juice, custard; white meat, soft and boiled; mashed vegetables and last of all bread. He recommends the following to combat the gastric irritation and thus allay the tendency to vomit:

℞.	Bismuthi subnit.	ʒv	20
	Aquæ	℥iii	90

M. Sig.: Shake the bottle and take the entire amount at one dose.

This may be repeated as necessary and warm fomentations applied to the epigastrium. This line of treatment may be continued for two weeks, when the following combination may be substituted:

℞.	Sodii sulph.		
	Sodii bicarb., āā	xlv	3
	Sodii chloridi	gr. xv	1
	Aquæ q. s. ad	Oii	1000

M. Sig.: Warm the solution and drink a glassful daily in divided doses.

Hemorrhoids.

The following outline of treatment is recommended by Preissmann in *Ther. Gaz.*, in the treatment of hemorrhoids:

℞.	Pot. iodidi	gr. xxx	2	
	Iodi (pure)	gr. iii		20
	Glycerini	℥i	30	

M. Sig.: Apply locally once an hour on absorbent cotton.

Or a stronger solution as follows:

℞.	Pot. iodidi	gr. lxxv	5
	Iodi (pure)	gr. xxx	2
	Glycerini	℥i	30

M. Sig.: Apply locally on cotton every two hours after taking a tepid sitz bath.

Iodin in Pulmonary Tuberculosis.

Delearde, in *Bul. Gen. de Ther.*, recommends the following combination containing iodin in the treatment of pulmonary tuberculosis:

℞.	*Tinct. iodi*	ʒiiss	10
	Pot. iodidi	gr. xv	1
	Glycerini	ʒv	20
	Syr. aurantii corticis	ʒvi	25
	Aquæ q. s. ad	℥xvi	500

M. Sig.: One dessertspoonful twice a day before meals well diluted in water.

This line of treatment seems to improve the digestion, acts as a tonic, and decreases the tendency to vomit.

Diabetes.

In the treatment of diabetes W. H. Thomson, in *Amer. Med.*, states that he rarely employs opium, codein or other opium derivatives, as they only relieve the symptoms for a time and do not change the nutrition of the tissues. The author recommends, as being of more permanent benefit, the use of cod-liver oil, and the younger the patient the freer the use of this remedy. So long as the stomach does not become deranged too much cod-liver oil can not be taken. It both diminishes the sugar and the excess of urea. Obesity and sedentary habits are contraindications to its use. Next to cod-liver oil the author mentions iron as a remedial agent in diabetes; acting as an oxygen carrier, it should be given in as large doses as possible along with plenty of fresh air. The following well-known combination is recommended in order to avoid constipation:

℞.	Ferri sulph.	ʒss	2	
	Pulv. senna			
	Pulv. *jalapæ*			
	Potass. tartratis			
	Pulv. zingiberis, āā	gr. ii		75
	Ext. gentianæ q. s.			

M. *Ft. pil. No. xxx. Sig.: One to three pills three times daily.*

Arsenic is also recommended, given in the form of arsenous acid or Fowler's solution.

For a speedy reduction in the amount of sugar the following combination is recommended:

℞. Antipyrini			
Sodii benzoatis, ãã	gr. xv	1	

M. Sig.: To be taken at one dose and repeated four times daily.

After a time the following containing aspirin is substituted:

℞. Aspirin	gr. xv	1	
Bismuthi salicylatis	gr. x		65

M. Sig.: At one dose three or four times a day.

In subacute cases the following outline of treatment is recommended:

℞. Benzosol	gr. xlviii	3	20
Sodii benzoatis	ʒiv	15	
Acidi arsenosi	gr. i		06
Sodii salicylatis	ʒiii	12	

M. Ft. cap. No. xlviii. Sig.: Two capsules one hour after meals and at bedtime; or:

℞. Sodii sulphocarbol.	ʒii	8	
Salicini	ʒi	4	
Phenacetini	ʒii	8	
Ammon. benzoatis	ʒiv	15	

M. Ft. capsulæ No. xlviii. Sig.: Two capsules one-half hour after meals.

If there be much insomnia the following combination is recommended, taken at bedtime:

℞. Strontii bromidi	gr. xx	1	30
Antipyrini	gr. xv	1	

M. Ft. chart. No. i. Sig.: To be taken at bedtime.

A dose of blue mass is administered once a week to patients after middle life. The following powder is of service in some cases to relieve the constipation:

℞. Sodii bicarb.	ʒiss	6	
Sodii sulph.			
Mag. sulph., ãã	gr. xxx	2	
Sodii salicylatis	gr. x		65

M. Ft. chart. No. i. Sig.: To be taken at bedtime.

Arsenic remains as one of the important remedies in diabetes, diminishing, as it does, the formation of glycogen. It has been recommended by Martindale combined as follows to form the bromid:

℞. Potass. carb.			
Acidi arsenosi, ãã	gr. xv	1	
Aquæ destil.	℥iiss	75	
M. Boil until dissolved. When cold add:			
Bromi	ʒss	2	
Aquæ destil. q. s. ad	℥iii	90	

Sig.: From one to three or five drops once or twice daily.

In the symptomatic treatment of diabetes, Stewart, in the "Text-Book of Applied Ther.," recommends a weak alkaline water such as Vichy or Apollinaris to relieve the thirst, which is usually present proportionate to the amount of sugar present. To allay the craving for food there is no better agent than opium or a little alcoholic stimulant. For constipation he recommends the following pill:

℞. Ext. cascaræ			
Ext. aloes, ãã	gr. ii		12

M. Ft. pil. No. i. Sig.: To be taken at night and followed the next morning by a saline laxative.

Lecithin.

In an abstract in *Med. Rev. of Reviews* Henri Labbé discusses the physiologic and therapeutic properties of lecithin which is extracted from the brain and from eggs. It produces favorable changes in metabolism, weight, appetite, urinary changes, osteogenesis, nerve elements and the blood. Therapeutically it has been found of great value in the treatment of rachitis when substituted for the phosphates; in neurasthenia and anemia it increases the appetite, restores strength and improves the general condition. In phosphaturia it can be substituted for the phosphates. It has also been found beneficial in the treatment of diabetes; in cachexias and in convalescence it restores strength, increases the flow of urine and in some cases it acts on the heart when digitalis fails. It has also been recommended in lymphatism of children and in tuberculosis. D. R. Brower has derived good results from the use of lecithin in neurasthenia in connection with or alternating with the glycerophosphates. He prescribes it in the form of the granular lecithin, giving 5 grains (.30) three times a day, or the glycerol of lecithin one dram (4.00) at a dose after meals. In rachitic cases it may be combined as follows:

℞. Lecithin (dissolved in chloroform)	gr. xxx	2	
Olei morrhuæ	℥iv	120	

M. Sig.: One dessertspoonful to a tablespoonful after each meal.

It has also been recommended in the form of an emulsion as follows:

℞. Lecithin	gr. vi-xii		25-.50
Pulv. acaciæ	℥ss	15	
Olei amygdalæ	gtt. xv	1	
Aquæ laurocerasi q. s. ad	℥iv	120	

M. Sig.: One tablespoonful three times a day after each meal.

Medicolegal.

Valid Release in Personal Injury Case.—The Supreme Court of Nebraska holds, in the case of Osborne vs. Missouri Pacific Railway Company, that a party who, having the capacity and opportunity to read a release of claims for damages for personal injuries signed by himself, and not being prevented by fraud practiced on him from so reading it, failed to do so, and relied on what the other party said about it, is prevented by his own negligence from asserting that the release is not legal and binding on him according to its terms.

Not Traveling Physician Under Statute.—The Court of Criminal Appeals of Texas reverses in Adams vs. State a conviction of the former of pursuing the occupation of a medical specialist traveling from place to place, without having paid the occupation tax prescribed by article 5049 of Sayles' Revised Civil Statutes of 1897. It says that the undisputed facts showed that he came to G. about May 1, 1903, and established and equipped an office; that he maintained an office at E., and at J. and B.; that he divided his time between these offices, and kept an assistant at each place, and treated patients at the places at stated intervals; that prior to coming to G. he had his headquarters and lived at M., and had practiced there and at J., and had lived at M. 18 months; that on leaving M. he moved with his wife and children to G., where they lived at a hotel up to within three weeks of the time of filing the information, when his wife and children went on a visit to relatives at Q. He received his mail at G., which was his headquarters, and practiced nowhere except at his offices before mentioned. In the court's opinion these facts did not constitute him a traveling physician as contemplated by said article 5049.

Expert Witnesses and Special Compensation.—The Supreme Court of Illinois says, in Chicago City Railway Co. vs. Handy, a personal injury case brought by the latter party, that it is competent to show that a witness has charged or expects to receive greater compensation than the fees allowed by the statute, and that he is in the employ of one of the litigants regularly or frequently as an expert witness, or to prove facts and circumstances which would naturally create a bias in the mind of the witness for or against the cause of either of the litigants. Expert witnesses are often found to be necessary, and while there is no good reason that any one who has the requisite special knowledge should not give testimony as an expert witness and receive greater compensation therefor than the fee allowed a witness by the statute, if the party calling him voluntarily consents to pay such greater compensation, still the fact that he receives such additional compensation may be very properly shown to the jury for their consideration when determining the weight and value of his testimony, and any fact which tends to show that he has the feelings of a partisan for the cause of one of the litigants or a bias against that of the other may be shown for the like reason.

Imputing to Another Infection with Venereal Disease.—The Supreme Court of Iowa holds, in the case of McDonald vs. Nugent, that to charge another with being afflicted with venereal disease is slanderous per se (by itself). It says that from an early date in the development of the common law of slander and libel, a charge made by one person that another is infected with a venereal disease has been held to constitute one of the few exceptions to the general rule applicable to oral slander—that, to be actionable per se, the words must impute some crime to the person defamed. Fortunately for the good name of civilized society, legal controversies calling for a consideration of this particular exception are comparatively rare, but its existence has been universally affirmed by courts administering the common law whenever they have had occasion to pass on a record like the one here before the court. The thought on which actions like this are held maintainable is not that the slanderous words impute a crime, but that the charge made, if true, or if generally believed to be true, would necessarily exclude the person thus impugned from the benefits of decent society. A charge of crime, in the ordinary sense of the word, is a mild and harmless imputation, when compared with words which brand a man or woman as a leprous outcast, and it is a healthful doctrine which holds to strict accountability any one who indulges in such injurious reflections on another. Where slanderous words, whether oral or written, are actionable per se, proof of the speaking or publication is all that is required. Malice in such case is presumed, without other evidence.

Fitting Glasses Not the Practice of Medicine.—The Supreme Court of Illinois says that there was nothing in the record of the case of People, for Use of Illinois State Board of Health, vs. Smith, recently before it, from which it could determine just what the complaint against the defendant was; but for the purposes of this decision, let it be assumed, as asserted by counsel, that the charge was a violation of Sections 7 and 8 of the act of 1899, to regulate the practice of medicine in this state—that is, by professing "to treat, operate on or prescribe for any physical ailment or any physical injury to or deformity of another," as provided in said Section 7, and being an itinerant vendor of an appliance for the treatment of diseases or injuries, as prohibited by Section 8. The finding of the Appellate Court was that all he did was to fit spectacles to the eyes of persons of defective vision, and sell them to such persons. By so doing, the Supreme Court goes on to say, he did not treat, operate on or prescribe for any physical ailment or injury or deformity of another, within the meaning of Section 7; nor did he, by advertising himself as an eye expert, and inviting persons afflicted with certain defects of vision to call on him, profess to treat, operate on, or prescribe for any physical ailment or physical injury to or deformity of another, but in the same advertisement stated that he did not give medical or surgical treatment. All that he asserted by the advertisement was that glasses fitted and ground by his method benefited, and had cured, headaches, blurring, itching, and burning of the eyes, etc. The Supreme Court also thinks it clear that he was not, under the facts here found, an itinerant vendor of any drug, nostrum, ointment, or application of any kind intended for the treatment of diseases or injury; nor did he, by writing or printing, or any other method, it says, profess to the public to cure or treat diseases or deformity by any drug, nostrum, or application, within the meaning of Section 8. It would be, it declares, a strained construction of that section to hold that the mere fitting of spectacles to the eyes of a person is an appliance intended for the treatment of diseases or injury to another. This statute is penal in its character, and must be strictly construed. It is a well-known fact that headaches, dizziness, and other similar ailments, often result from defective vision, which may be relieved by the use of spectacles; but it can not be seriously contended that the person who sells such spectacles, or who tests the eyes and fits such glasses, practices medicine or surgery, or professes to cure or treat diseases or deformities thereby. While the statute under consideration is a wise and humane regulation for the protection of the public, and should be rigidly enforced, the construction here contended for could have no other effect than to bring it into disrepute. And the Supreme Court thinks that, on the facts recited in the judgment below, the Appellate Court ruled properly in holding that the evidence did not warrant a conviction.

1. **Pancreatic Diseases.**—Deaver and Müller's article discusses the subject of pancreatic disease in full, pointing out the necessity of surgical operations in cases of this disorder. In the acute forms the indications for operation are indicated by the pathology of the disease and the history of the cases. The diagnosis is difficult. The symptoms are often ill-defined so that the mortality is often high, and the time for operation is open to considerable question, but early operation rationally conducted is advisable according to Mikulicz. The technic varies with the nature of the condition. If fat necrosis is found on opening the abdomen, it is a symptom of great importance indicating diffusion of the ferment and decides the diagnosis. The bile passages should be carefully explored, especially the common duct, and the intestines and surrounding viscera carefully protected. The pancreas can be reached through the gastrocolic omentum below the stomach; through the gastrohepatic omentum above the stomach; through the transverse mesocolon back of the colon and stomach. The first method is most applicable for the purpose of drainage. It consists in dividing two layers of the peritoneum forming the gastrocolic omentum, raising the stomach and then cutting through the ascending layer of the transverse mesocolon. If the pancreas presents merely a swollen, tense, edematous appearance, without marked pancreatic involvement, an incision should be made in the long axis of the organ, extending its entire length. Drainage to this opening, though uphill, will sufficiently provide for the serous effusion and broken down cellular products. When there is severe peripancreatic involvement or great necrosis of the gland and fat, loin drainage is required after free incision of the pancreas. It is useless to try to dissect out the necrotic foci. The loin incision is made at the left costovertebral angle. Abscess, necrosis and gangrene require the same treatment. If there is stone in the gall bladder, the operation is seriously complicated as the incision is not best located for cholecystostomy, but in such cases removal of the gallstones and the establishment of an external biliary fistula greatly adds to the chances for recovery. If the stone is in the common duct great care will have to be taken to prevent subsequent peritonitis. The surgery of chronic pancreatitis is much more favorable of late years, and the history of the operations is briefly given and the technic treated. The cause of the disease must be removed, if a biliary or pancreatic stone, and temporary or permanent drainage of the bile be provided for. In cysts the operative procedure will depend on the degree of the adhesions surrounding the structures. This makes it difficult unless the cyst is pedunculated, which is rarely the case. Aspiration of cysts should only be performed when the patient is severely ill from diabetes or the effects of pressure. The cysts will always refill and the danger of leakage is great. When practicable the abdomen should be opened by a median incision above the umbilicus and by incising the gastrocolonic omentum or the transverse mesocolon. The cyst contents should be withdrawn with an aspirating needle, and as it is removed the puncture be

closed with one or more hemostats. The cyst wall is then drawn to the wound, sutured to the parietal peritoneum and drained. When it can not be brought to the abdominal wound, a rubber drainage tube should be introduced into the cavity of the cyst and surrounded with careful gauze packing to prevent leakage.

2. **Diabetic and Non-Diabetic Glycosuria.**—Stern points out the characteristics of diabetic and non-diabetic glycosuria and the possibility of their occurring simultaneously, reporting cases. His conclusions are given as follows:

1. The diabetic state may be well established before glucose is excreted by the urine. Diabetic glycosuria is nothing more than the salient feature of the second stage of the diabetic deterioration.
2. Glycosuria is a symptom, an enunciation of manifold other disturbances of ectogenous, as well as of endogenous causation.
3. With the assistance of various discrepant factors we are enabled to differentiate clinically between the diabetic and non-d'abetic form of glycosuria.
4. Duplex melituria is the result of two concurrent or intercurrent affections of dissimilar character, having the one symptom, glycosuria, in common.
5. The recognition of duplex melituria depends on the alternate prominence of one set of symptoms, including the respective glycosuria.

3. **Epilepsy.**—Spiller quotes from Hughlings Jackson in regard to the occurrence of certain fits which begin in the gustatory localization of the brain for which he has proposed the name "uncinate group," and reports cases. In one case there were also severe submucous hemorrhages in the face and right upper limb, producing decided trouble, which is a rare feature.

5. **Appendicitis.**—Brown believes in Ochsner's method after extirpation of the appendix. In his practice he has found it a valuable resource in the after-treatment.

6. **Astigmatism.**—From a study of 900 cases examined and re-examined, Pohlman found that nearly every third one showed changes in astigmatism; 50 per cent. presented simple increase in the quantity without a change of the axis; 31 per cent. gave merely a change of the axis. These two combined accounted for 81 per cent. of the total. The other 19 per cent. were almost equally divided between 1, increase of astigmatism plus change of axis; 2, change of regular to irregular, and 3, change of irregular to the regular cases. He remarks it would be interesting to know if a similar series of other observers would give like results.

13 Tertiary Syphilis of the Nose and Pharynx. (Concluded.) W. Scott Renner.
14 The Treatment of Paraphimosis. (Concluded.) J. N. Weller, Everett S. Hicks and R. C. Fish.

9. **Uterine Curettement.**—Craig thinks that this operation is not dangerous in the hands of a skilled operator, and that there is too much exaggerated statement as regards the danger of vaginal infection and too much downward traction in operations. He also believes in minimum dilatation without trauma to the cervical tissues. The greatest danger is the perforation of the uterine wall, which he thinks may occur without symptoms. The determination of the exact shape and depth of the uterine cavity should be determined beforehand. With the uterine curette-forceps of Emmet for the fundal and cornual mucosa the need of upward pressure is diminished and the danger of perforation is lessened, and the skilled curetter would know at once what the conditions are. The operator's sense of touch should be constantly on the alert and injury to the intestines in cases of perforation can hardly occur with one of experience. He does not favor the tampon. He thinks it more rational to clean the cavity and leave the blood and exudates to drain through the dilated cervix and wash away the organisms. The postoperative douche should be avoided as a rule for the first forty-eight hours until the cervix has had a chance to contract and there is no danger of transferring anything from the vagina to the uterine cavity. Of course, there may be cases where thorough uterine douching may be required.

10. **Appendicitis in Young Children.**—In 250 cases, seen since January, 1902, by Erdmann 29 occurred in children under 10 years of age. All the cases were acute; 22 were operated on with a mortality of 2. The appendix was removed in every instance. The youngest was 3 1/6 years and the oldest 10 years. He has also removed the appendix nine times in infants from four months to eight months of age during the same period. These ~~were intussusception cases and have no special bearing on the question of~~ appendicitis. The diagnosis under 10 years is difficult. Objective signs must be chiefly relied on, and a careful history and study of the cases if necessary. Pneumonia or pleurisy of the type with lower intercostal pain is difficult to exclude the first day or so, but as the pulse becomes very rapid and the face anxious appendicitis may be diagnosed, while accelerated breathing and a livid or flushed face indicate pneumonia. In the very young we must rely on the symptoms of pain manifested by fitful crying and sleep, abdominal tenderness, rigidity of the right lower quadrant after the first few hours, absence of blood and bloody mucus in the stools, high pulse and temperature, the tumor fixed, and in the classical region if the illness is of long duration and at this time a temperature typical of pus. Almost invariably the little patient unconsciously places his hand in the region of the appendix to ward off manipulation. This sign is almost pathognomonic. ~~Erdmann describes at length his method of operation.~~

11. **Post-Operative Pneumonia.**—After reporting a case, Holmes discusses the general subject and reviews the literature. He thinks it is much more correct to speak of post-operative pneumonia than it is to speak of anesthetic or ether pneumonia, for statistics show that pneumonia was as frequent before the anesthesia period as it is now after operations, and that it occurs also when local anesthesia is utilized for major operations. General anesthesia, therefore, does not materially increase the danger of pneumonia if the lungs are in good shape. Moreover, if there is an increased probability of pneumonia with ether than after chloroform, it is so slight as not to outbalance the greater danger of the latter agent. He advises care in giving the anesthetic, administering it slowly, not too much, keeping the patient warm during the operation and changing the position as soon as possible after it to avoid hypostatic congestion, etc.

12. **The Spoon as a Medicine Measure.**—Miller points out the inaccuracy of the teaspoon or tablespoon for drug measurement, for either solids or liquids, and gives some tests of them with sugar of milk. A teaspoon will hold 50 to 100 grains as it is leveled or piled up, and a tablespoonful may range anywhere from 150 to 215 grains, more or less.

15. **New Treatment for Fracture of the Neck of the Femur.**—Whitman advocates the treatment of fracture of the femur by overcoming the deformity by abduction of the limb and fixing by a spica bandage. In case of complete fracture, after overcoming the shortening by traction, the limb should be abducted to utilize the tension on the capsule to direct the outer toward the inner fragment contained within the acetabulum and bring them into more or less accurate apposition. Complete abduction makes the muscle contraction powerless to induce deformity. Fixation is most directly assured by contact of the neck with the rim of the acetabulum and of the trochanter with the side of the pelvis. In this attitude the support of the plaster bandage should provide the rest needed for repair. This method, which was first suggested for fractures in children, is now advocated as a routine measure for all cases of fracture of the neck in which local treatment is to be desired. The details are given as follows:

A piece of ordinary seamless shirting, such as is used for plaster jackets, about six feet in length, cut and sewed in a shape to cover the body and the limb, *is first applied* and is fixed securely in place by bands passing over the shoulders. This is threaded with several long bandages, the "scratchers," designed to keep the skin in good condition. It is also advisable to insert a substantial "dinner pad." The patient is then anesthetized and is placed in position for the application of the bandage. The head and shoulders may be conveniently supported on a box of proper length and about eight inches in height; the pelvis rests on a sacral support. This is a thin plate of steel about the size of the hand, of a trowel or heart shape, carried on an upright bar fixed to a wide base or screwed to the end of the table. Such a support is almost indispensable, because it does not interfere with the proper application of the posterior surface of the spica, as do the blocks or other supports in common use. A wide, firm band of cloth is then carried about the perineum, the two ends of which united over the shoulder and held by an assistant furnish counter traction. If *the fracture is incomplete, as is usual in young subjects,* the limb under gentle traction is slowly abducted, an assistant at the same time abducting the sound limb to prevent the tilting upward of the pelvis, and to demonstrate the normal range. If the fracture is complete, the shortening is first entirely overcome by the traction and counter traction. The limb in the extended attitude, under traction, is slowly abducted by the assistant until the trochanter is fairly apposed to the side of the pelvis; the operator meanwhile pressing the trochanter *downward and inward. In some instances* there is a distinct snap as the outer part of the neck slips beneath the rim of the acetabulum, and in any event the abduction is increased until the trochanter is firmly apposed to the side of the pelvis. In the first instance the *primary object* of the abduction is by leverage against the upper border of the acetabulum to overcome the deformity: in the second, by tension on the capsule to remove folds to appose the fragments and by actual contact of the bone with bone to oppose redisplacement.

The limb being held in this attitude, the pelvis, the ribs, the bony prominences of the knee and foot are protected with layers of sheet wadding, and the limb and body are then covered in carefully with cotton flannel bandages, which are in themselves a protection against pressure. A plaster spica is then applied, extending preferably from the mammary line to the toes. This should be drawn snugly about the hip, and most important of all, should completely enclose and support the buttock, not only to provide antero-posterior support, but to prevent the excoriations that are inevitable if the tissues are allowed to hang over the edge of the plaster. The insertion of thin strips of wood or iron about the hip and knee permits of a lighter bandage than would otherwise be possible. When the bandage is completed it is carefully cut away to allow complete flexion of the sound limb, the shirting is drawn over the edges of the bandage, carrying beneath it the cotton, and is sewed preferably to an outer cover of shirting drawn over the bandage. Thus a smooth, even surface is apposed to the body and the skin may be kept in condition by drawing the friction bandages back and forth at intervals. These bandages, popularized by Lorenz, are always placed beneath the body part of the spica and with the exercise of a little ingenuity their use can be extended to the limb also.

For greater precaution it *may* be *advisable* to cut openings in the plaster at all points where pressure is feared, and a part may be cut away from the front of the body part if the constriction is too great.

As a rule he finds this support comfortable, and the patient can be moved or even move himself. A long spica is most efficient in preventing rotation of the limb, but a short spica can be used in impacted or incomplete cases. The steps in the application are the same excepting it is more accurately molded about the pelvic crests and the joint, and is made especially thick and strong and then cut away so that a band not more than four to six inches in width remains across the front of the abdomen. The lower end may be carried a little below the knee or cut away to allow free movement of the knee if desirable. A short spica permits the patient to assume a semi-reclining position and if the limb were slightly flexed, he can practically assume a sitting posture. If a long spica is used at the end of four weeks it may be shortened to allow the action of the knee and at the end of eight weeks, if union is assured, it can be removed, followed by massage, passive movement and voluntary motion, but the limb should not be used to support the weight for *at least four months.* Crutches and a hip brace should be employed. A *short* plaster spica holding the limb in moderate abduction may be used. Of course, this treatment is adapted to the favorable class, but he thinks it can be used in practically any case with modifications as suggested.

16. The Ferments of Cow's Milk.—The history of the discovery of these bodies in cow's milk is reviewed by Lesperance, who holds that we have definitely determined the presence of trypsin and pepsin, of the lipasic and oxidizing ferments, and of a glycolytic ferment in cow's milk. There is reason to expect still further discoveries in this direction.

17. Kidney Fixation.—The methods of kidney fixation are reviewed by Johnson, who finds that the better methods of nephropexy are ordinarily successful. To select one method as superior to another is impossible. Nearly all those at present in vogue produce in the majority of cases sufficiently firm fixation of the kidney. As for sutures, he believes catgut possesses advantages over all other non-absorbable materials.

19. Dilatation of the Bladder in Cystotomy.—Blasucci discusses the amount of dilatation that the bladder can safely stand in case of operation, and concludes that a careful injection has no dangers. Limited dilatation of the bladder is preferable to none. Anatomical researches in regard to the ascent of the peritoneal fold are of little or no value to the surgeon, and we find in practice more working space than these researches would indicate. There are practically no cases where suprapubic cystotomy is indicated in which dilatation of the bladder can not be carried out. In case of female fistulous bladder and a bladder torn by trauma he would use a collapsible balloon, which should be inflated within the bladder after it is inserted, as devised by Dr. Vetere of Naples. The method of using it is very simple, and it has also the advantage of preventing the effusion of liquid in the suprapubic wound when the bladder is opened.,

21. Primary Pyelitis in Infants.—Hartwig remarks that while there is possibly some mention in the literature of this disease he has not observed it. Postmortem two cases were found to his knowledge, and he thinks the condition is not very rare. Failure to recognize the disorder, which was not known to Ewald when he lectured in Buffalo recently, depends on the fact that nothing but a careful urinary examination reveals it while its general impression is that of typhoid fever. He would urge in all doubtful cases of typhoid fever a careful examination of the urine for primary pyelitis.

29 *Forensic Eye Aspects of Tabes. Jas. G. Kiernan.

22. The Individual Equation of the Patient in Surgical Operations.—Estes points out that the history, environment, habits, personal disposition, age, sex, nativity, physical condition, extent and locality of the operation all have their influence on the result. He thinks it is the surgeon's duty to obtain all the data which will enable him to determine the importance of each of these points in any case he has to operate on. This must be done by obtaining a careful history of the patient, including the family history, and by a thorough physical examination, calling to his aid the laboratory, and he should also include a urinary examination in the personal physical observation. He thinks it is more difficult to determine when not to operate than it is when to operate, and far more important in many instances.

23. Valvular Disease of the Heart.—From the study of the conditions of valvular disease illustrated by the report of a case, Burt summarizes as follows:

Judicious treatment of a patient with valvular disease of the heart presupposes a knowledge of the distinction, and an ability to discriminate clinically, between adequate and *inadequate* compensation; possibility is *one thing,* probability is another, and finality quite another in the prognosis of these affections; although not always feasible, it is nevertheless desirable frankly *to explain* the situation, where dilatation from valvular defects is balanced by hypertrophy, in order to forestall a fortuitous disturbance of equilibrium; ordinary occupations and recreations not too strenuous need not necessarily be abandoned; systematic *outdoor* exercise, preferably walking, is *not only* permissible, but, to maintain the integrity of the heart muscles, actually indispensable; violent exertion, exciting emotions and excessive eating and *drinking* are positively injurious; temperateness in *all* things pertaining to daily existence should be the watchword; with failing compensation absolute rest is of paramount importance, and, not infrequently, all that is necessary for rehabilitation; digitalis in this condition irrespective of the valve *affected* when drugs are required is the sole remedy that can not be dispensed with; large doses may be given for a short time and small doses *for a* long time or indefinitely; strophanthus is *one of the most* reliable substitutes *for* digitalis; nitroglycerin, calomel, aconite, iron, arsenic, magnesium sulphate and strychnin are valuable adjuvants; maximum doses of strychnin should not be continued *for* extended periods without intermission; finally, ruptured compensation is the beginning of the end, however long deferred by intelligent management.

24. **Epigastric Pain.**—Murdoch points out the various conditions which may produce epigastric pain and their symptoms, reporting cases.

25. **Pus and Blood in the Urine.**—Douglas' article is a general statement of the conditions in which pus and blood may occur, and differentiation of the locality and form of the disease.

27. **The Theatrical Profession as a Disseminator of Disease.**—Brown concludes from his observation and studies that the theatrical profession is a factor of some importance in the dissemination of scabies, pediculosis, syphilis and gonorrhea by reason of its peculiar sociologic position. This influence is greater in the traveling troupes than in stock companies on account of the lack of accommodations and unhygienic conditions endured, and the living apart from the rest of the world. Moreover this class lack the proper medical information which might aid them, and the lack of time prevents them from consulting a medical man in the large cities excepting when physically incapacitated. They, therefore, fall into the hands of unscrupulous and ignorant quacks. This applies, of course, to the poorer class of actors, as successful actors are not included in this category. He thinks the remedy is not exactly clear. While the effects of the parasitic diseases mentioned are not dangerous, they are annoying, and should be prevented. Facilities for frequent bathing should be provided, and accommodations at the theaters should be such that the lesser lights can properly care for themselves. The manner in which the costumes are handled can not be too harshly condemned. With the resurrection of old costumes for a revival of any kind, it is scarcely less than miraculous that all the diseases known to man are not equally distributed throughout the company. The sterilization of these costumes at least once would do no material harm, and would greatly aid in preventing disease. It does not, however, necessarily follow that because an individual is on the stage that he is entitled to all these diseases or specially subject to them.

29. **The Eye Aspects of Tabes.**—Kiernan points out that the Argyll-Robertson pupil exceptionally occurs in many other conditions than tabes. It may occur in alcoholism as well as in parasyphilitic disorders. Its frequency in constitutional syphilis is over-rated.

30 *The Relation of Some Special Causes to the Development of Neurasthenia. Robert T. Edes.
31 *Intra-abdominal Rupture of Ovarian Cysts. With Report of a Case. Ernest B. Young.

30. **Neurasthenia.**—Edes reviews the various causes of neurasthenia and doubts the frequent effect of overwork, but admits that it is possible. He quotes the instance of James Russell Lowell when preparing the "Commemoration Ode," and remarks that it was not neurasthenia, though he was some weeks in getting over the effects of the work. Moreover, if a lesser man had his bread to earn by performing a similar task every week and was aware that he was not doing it well, he would need but little outside pressure to bring him dangerously near the line. Then if, according to Stiller, he were pale and lean, and his tenth rib were not united by cartilage to the sternum, or if, according to Glénard, his abdominal viscera were not firmly fixed in their places, or if, according to Bartholow and many others, he were to try to indulge in that ease and luxury which are not very likely to come to a man in his position, or if he tried to brighten himself up with alcohol, tobacco or cocain, or if, according to the Austrians and French, he appealed to Venus rather than to Bacchus for relief, or if, according to Stevens and Ranney, he could not easily converge his eyes on his paper, or, according to Gould, could not focus them in their different diameters alike, he would surely cross the line. If he had done or suffered all or several of these things it would depend on the physician into whose hands he fell to say which of them was responsible and whether he should get good advice, etc., have new spectacles or get his eye muscles cut or get baths, calomel, etc., and go off a well man. Edes is in doubt as to the effect of many of these causes, and would not put full faith in them singly. He likewise considers lithemia as insufficient. He concludes his paper with a gentle criticism of Gould's recent utterances in regard to eyestrain as a cause. He considers that the unquestioning acceptance of any one of these factors or its overwhelming prominence in the mind of the practitioner, tends to relieve him of the responsibility of making the decision as to which is operative in the case before him, but his knowledge of the possible presence of any one or any two or three of them places it on him rather than on the specialist. It is too much to ask of any man that he should be familiar with the details of all the specialties, but he should be able to follow the more important signs far enough to decide when to call in his brothers, whose knowledge is more restricted and consequently more precise, and whose treatment can be more accurately adapted to each individual patient.

31. **Rupture of Ovarian Cysts.**—Young begins with a résumé of the literature and then reports a case, following it with a general discussion of the symptoms, treatment, prognosis, etc. He believes that early operative treatment is indicated according to the general consensus of opinion. The statistics of the mortality certainly bear out this idea.

33 Smallpox—the Importance of Its Early Diagnosis. T. J. Shoemaker.
34 Home Treatment of Anomalies of the Ocular Muscles. Derrick T. Vail.
35 Physiologic and Psychologic Impotency. W. P. Ford.

32. **Retrodeviations of the Uterus.**—Tate finds that the theory that the perineal body has anything to do with keeping the uterus in its natural position has now very few adherents, but he thinks it is of some importance. There is no normal position of the uterus. The influences of the subject's position, fullness or emptiness of the bladder, etc., all have their effect in changing its position. The non-surgical treatment of misplacements depends mainly, in his opinion, on the general health of the patient, whether an actual cure of the retrodeviation is obtained or not. Pessaries are defective and may produce trouble, and massage has been tried and found wanting. Electricity, he thinks, has probably done more harm than good in these cases. Pregnancy may or may not be the means of curing the displacement, but certainly many cases have been benefited. Surgical treatment is necessary where complications exist. If there is a pelvis full of adhesions there is no use doing any mere tinkering; above all, do not practice massage. From his own experience he advises the Gilliam and Kelly methods. For uncomplicated retrodeviated uterus in young or middle-aged women he prefers Gilliam's method, the steps of which he describes. If the case is one after the menopause he always makes fixation after Olshausen's method, as modified by Kelly, but carrying his ligature through not only the peritoneum, uterus to peritoneum consecutively, but fascia as well. This gives a firm anchorage and holds the uterus very securely. Vaginal operations seem to him unsatisfactory.

40 *Delirium Grave. A Critical Study, with Report of a Case with Autopsy. William B. Pritchard.
41 *Paralysis Agitans; Some Clinical Observations Based on the Study of 219 Cases Seen at the Clinic of Professor M. Allen Starr. T. Stuart Hart.

38. **Epilepsy.**—From the analysis of symptoms, causes, etc., Starr concludes that an epileptic attack is a symptom of a more general disease. The disease is a disorder of control over inherent energy, and its existence is proof of a weak or defective organization of the brain. Any lesion, no matter where or what, may interfere with control and give rise to the symp-

tom. He thinks in view of these facts it is better to say that epilepsy is an organic disease of the brain characterized by lack of control over the mechanism of motor energy.

40. **Delirium Grave.**—Pritchard has studied this condition, and thinks it is a distinct psychosis which is very inadequately treated of in most text-books. The best clinical description of the disease is that given by Spitzka. A case is reported in detail. Treatment seems to be comparatively ineffective.

41. **Paralysis Agitans.**—Hart analyzes the cases of this disorder observed in Dr. Allen Starr's clinic. He found that it occurs twice as frequently among men as women; rarely before the thirtieth year. It is not especially a disease of old age, but rather of the pre-senile period. A direct heredity could rarely be found, but there is a considerable proportion of cases with nervous heredity. In only 16 per cent. of the 219 analyzed had any of the relatives been similarly affected. Among the chief causal factors are emotion and traumatism. In 12 of the cases previous infectious disease was reported and associated with the nervous disorder. He thinks we are far from solving the real etiology of the affection, but all the factors that have been suggested have a common general weakening influence on the organism and particularly on the nervous system. Tremor is the first symptom noticed by most patients. Rigidity was observed in 142 cases; contractures were noticed in 28, and a tendency to fall was observed in 173 cases. The deep reflexes were increased in 188; 90 were normal; in 30 they were diminished; and in 68 they were exaggerated. The Argyll-Robertson pupil was present in 2 and voice changes were noticed in 120 cases. Pain when present was, as a rule, not severe. Paresthesias of various kinds were present in 120 cases and hyperidrosis and restlessness were also not uncommon accompaniments. The pulse rate was above 100 in 30 and various complications were observed; they seemed to be coincident affections. Two cases complicated by hemiplegia are described in brief detail. No cures are reported, but in a number of cases there seemed to be an arrest of the disease. The treatment consisted mainly in removing the sources of anxiety and worry, relief from exhaustive and laborious occupation, attempts to improve the general nutrition, the use of moderate exercise, the systematic use of massage and hydrotherapy. In a number of cases electricity was used, but with no noticeable effect. None of the drugs recommended proved regularly beneficial. Those of most value were hydrobromate of hyoscin and sulphate of duboisine. These appeared to diminish the tremor and relieve the insomnia for the time. General tonics such as iron and strychnin were of value.

42 *A Study of the Climate of Long Island. William H. Ross.
43 Treatment of Fractures. James P. Warbasse.
44 *Injury as an Alleged Cause of Certain Nervous Diseases. C. P. Gildersleeve.
45 Granular Lids. B. C. Collins.
46 Bradley Parker, M.D. William Schroeder.

42. **The Climate of Long Island.**—Though Long Island is one of the oldest settled parts of the United States, Ross remarks that its healthfulness is little appreciated by the medical profession. It is thought to abound in marshes, malaria and mosquitoes, but practically the opposite is true. It is approximately 15 miles wide and 120 long, with 250 miles of water front, counting its bays. It is the only considerable part of the Atlantic coast entirely surrounded by water. Its geographical formation is glacial. The island is mainly made up of sand and gravel and fine strata of clay, dipping from north to south. The ground water flows from north to south and the character of the soil modifies the climate. There is less fog than in any other section where clay land abounds more, and the water is excellent. The mean summer temperature is 70, and the mean winter 30; the mean annual temperature is 51.8. The annual range is 39 degrees, as compared with 64 to 70 and more for the whole country. The relative humidity is low, especially in the pine region. The average number of clear days is 70 more than New York City, 90 more than Nantucket and 120 more than the western part of the state. The eastern part of the island has only 12 days less sunshine than Denver and 30 less than Phoenix, Ariz. The wind direction in the summer is from the south and southwest off the Atlantic ocean, and in the winter the prevailing wind is from the northwest, producing a continental type of climate, but there are considerable periods when the wind is from the southwest and the tempering effect of the ocean is again felt. The pine forests of the island occupy the portion between the central range of hills and the south shore, six to eight miles in width, and extend for sixty miles. There is no evergreen forest in the state of New York of equal size other than the Adirondacks. Evergreen forests have a powerful purifying effect on the atmosphere, rendering it antiseptic, and, with the aseptic ocean air, which for more than six months of the year is carried through the district, the sandy soil, relatively low humidity, and large amount of sunshine, Long Island presents climatic features in its pine forest region not surpassed by any place along the Atlantic coast. Of the 3,935 deaths in 1885-6-7 of persons over twenty years of age, 1,394 were between 70 and 90 years, 642 between 80 and 100 years, 111 between 90 and 100, and 4 over 100. This is a remarkable showing, which Ross thinks is hardly equaled anywhere in the country. He thinks the climate is especially favorable for the convalescent from acute diseases, in surgical diseases to accelerate tissue change, where an equable temperature is desired, for pulmonary tuberculosis, neurasthenia, nerve exhaustion and other nervous troubles and insomnia. Tuberculosis is one of the rarest diseases among the natives and rheumatism is scarcely more frequent. Malaria does not exist except at some sections at the western end.

44. **Injury as a Cause of Nervous Diseases.**—Gildersleeve discusses the severe nervous disorders which are sometimes attributed to trauma, such as multiple sclerosis, though there is very little evidence of this condition being primarily caused by trauma. Similarly with locomotor ataxia. Trauma may be the exciting cause in a syphilitic subject, but as to its being the primary cause, he questions it. He doubts also whether it can be secondary to injury of the peripheral nerves, causing an ascending neuritis, as has been held by some others. Paralysis agitans is another disorder which is frequently ascribed to trauma. He has no doubt that certain injuries are perfectly competent to cause that disease. Neurasthenia and hysteria are also disorders that can be due to trauma, and are serious enough to be entitled to recognition by the surgeon as actual morbid entities.

48. **Colon Dilatation.**—The patient operated on by Fleming, a man 25 years of age with good general history, had suffered nearly all his life from lack of proper defecation and consequent deformity of the abdomen. All sorts of cures and drugs were tried without good results. The operation was by laparotomy and the dilatation of the colon, which resembled an ovarian cyst, extended from about three inches from below the splenic flexure to the anus, and in the illustration apparently occupied nearly the whole lower portion of the abdomen with its sac-like distention. The removal of the sac was considered feasible, owing to the long mesocolon, but too dangerous, and the formation of an artificial anus was not desirable. Plica-

tion of the sac was deemed the least dangerous procedure. The operation consisted in plaiting the sac longitudinally from one extremity to the other. Seven or eight folds were taken altogether, being held by continuous chromic catgut sutures, which not only included the peritoneum, but also some of the thickened wall. After the folds were completed the sac was reduced in size to about four inches in diameter. Through fear of kinking it was suspended at its upper extremity by a catgut suture to the abdominal wall. The abdomen was then closed. The patient left the hospital in four weeks, notwithstanding an attack of catarrhal pneumonia which occurred after the operation. The bowels were regularly moved by enemas and selected diet used. He was greatly improved and his bowels moved with cathartics and enemas, which was not the case before the operation, and not infrequently spontaneous movements have occurred. Fleming remarks that he is not aware of a previous operation of this kind for this purpose, though a similar one has been used in cases of dilated stomach.

71 Professional Courtesy. P. S. Root.
72 Recent Progress in Laryngology. Wadsworth Warren.
73 Epilepsy as Viewed from the Standpoint of the Sufferer.

68. **Cervical Lacerations.**—The relative value of trachelorrhaphy or amputation in cases of cervical laceration is treated of by Yates, who thinks that the Emmet operation is unfitted for conditions of great hypertrophy and hyperplasia, or where the greater part of the cervix is composed of scar tissue. The operation, which he considers most satisfactory in such cases, is that devised by Newman, published in The Journal of April 21, 1901, and which he here fully illustrates. The Emmet operation is one of choice only where there is little adventitious tissue and the pathologic conditions are both recent and simple.

70. **Intratracheal Injections.**—Anderson advocates the use of intratracheal injections in lung diseases and gives the results of experiments performed on dogs to show the absorbability of medicaments thus introduced. The best vehicle he finds is pure olive oil and he claims that the clinical use of intratracheal injections is feasible. Thousands of such have been given without injury and in most cases with great benefit. The advantages of olive oil are that it is a solvent for most of the drugs that need be used, and the claim that it is not absorbed is not borne out by his experiments nor by large clinical experience. The drugs used should be non-irritating, freely soluble and not be employed in poisonous doses. He finds that such drugs as guaiacol, camphor, menthol, iodoform, iodin and some of the essential oils are most useful. Most of his patients were given a combination of camphor, menthol, guaiacol and eucalyptus. The solution should be warmed to body temperature before the injection is made. Two illustrative cases are reported.

83 The Angle Gamma and Its Relation to Strabismus. Frank E. Brawley.

81. **Entropium.**—James has operated by the method described to him by Dr. Frank Allport as follows:

> Stretching the skin of the lid as much as possible from the border upward, three or four sutures are placed in it in this manner: Pass the needle with a strong silk suture directly through the lid at or near the upper border of the cartilage, being careful to engage the cartilage with it and then pass it back again, leaving a space of from three-eighths to one-quarter of an inch between them, and tie firmly. Three of these were so placed, one in the middle of the lids and one each side half way between the first and the inner and outer canthus. These sutures were left in one week, when they were removed. By this means cicatricial adhesions are formed between the skin and the upper border of the cartilage, thus permanently everting the lid border. The operation is quickly done, and has in the past served me satisfactorily in mild cases where only a few hairs were the aggressors; but I have never before attempted it, where there was complete entropium of both lids, and where all the lashes were resting on the cornea, as in this case, and much to my surprise and delight, the result seems at this time to be as nearly perfect as it could be.

He finds this operation in mild cases extremely satisfactory and the results as good as other operations with better cosmetic effects.

87 *Medical Science, the Medical Profession, the State and the People. Charles H. Hughes.
88 The Gentleman Degenerate.

84. **Mixoscopic Adolescent Survivals.**—Kiernan's article is continued. This installment is especially devoted to certain phases of Rousseau's career as an illustration of the conditions described.

85.—See abstract in The Journal, xl, p. 1527.

86. **Clinical Lectures in Psychiatry.**—The subject of Wernicke's twenty-seventh lecture is chronic and protracted alcoholic delirium, the polyneuritis psychoses, and presbyophrenia or senile insanity. It terminates with the description of a case of a peculiar form of what he calls *acute allopsychosis* or marked hallucinatory insanity with motor restlessness and confusion, inability to recognize surrounding objects and illusions of location, etc. The lecture is to be continued.

87. **The Medical Profession and the State.**—Hughes' memorial address goes over the progress of medicine in detail, calling especial attention to the public duties of the physician. He says there was never a time when great and capable medical men were as much needed as now by the state. The people must learn what the medical profession knows and legislation should be directed for public health and public physical welfare. The more medical men who go into public service the better for the people.

89 *Notes and Observations on Uncinariasis in Porto Rico. (To be continued.) Bailey K. Ashford and W. W. King.
90 Croupous Pneumonia; Its Prevalence and Treatment. Adrian A. Landry.
91 *Normal Salt Solution and Butter as Stimulant and Nourishment, Subcutaneously and Cutaneously Administered, in "Swamp," Enteric and Scarlet Fevers. S. L. Williams.

89. **Uncinariasis.**—The history of uncinariasis and an account of its prevalence in Porto Rico are given by Ashford, who speaks very highly of the work done by the Tricoche Hospital at Ponce. The trouble in Porto Rico is that the laborer defiles the soil and infects himself and his children. The remedy is in the establishment of latrines and the systematic enforcement of their use, public education as to cleanliness, the wearing of shoes, etc.

91. **Salt Solution and Butter as Stimulant and Nourishment.**—The title of Williams' article explains the subject, but the account of his experiences with the remedies is of interest. He reports cases where life has been apparently saved after every other means had failed by subcutaneous *injections* of salt solution and inunctions of butter *cutaneously*. *His* experience impresses him with the great absorption through the lymph capillary system and the helpfulness of keeping the skin epithelium nourished, especially in diseases where the high stages of hyperemia and the desquamation react on the nervous system. His plan in using salt solution is to insert two ordinary hypodermic needles, externally, below *the* hip-joint and *alternately fill and slowly force syringeful after syringeful*, according to the demands, using gentle massage after these injections until the results are obtained or abandoned as hopeless. With butter there is but one simple means of applying it; spreading it over and rubbing it in where the skin is thin, or all over the body when there is *fever or nervous* excitement.

92. **Spermaturia.**—Elliott notices the conditions that cause a morbid loss of semen, calling attention to the fact that such may produce transient albuminuria. There may be a physiologic presence of seminal elements in the urine, as after sexual excitement or coitus, but there are numerous pathologic conditions, such as chronic inflammation of the prostatic urethra and ejaculatory ducts, together with dilatation and atony of the same usually following gonorrhea and urethral stricture, vesical prostatitis, habitual catheterism, hemorrhoids and venous excesses or masturbation, when spermaturia may be found in the urine almost constantly. Tabes dorsalis and traumatic lesions of the spine and myelitis have also been accompanied by it, and it has been observed in hysteric neurasthenia and in cases of spinal neurasthenia during violent exercise. The urine voided during or after epileptic seizures is found pretty constantly to contain seminal elements. He notices particularly the clinical tests where albumin reaction is obtained, such as Heller's test, where there is a faint reaction rather less than with heat and nitric acid. The potassium ferrocyanid test gives a distinct reaction which is not affected by heat, though it does not develop so quickly as with ordinary urine albumin. The potassio-mercuric-iodid and picric acid tests give plain reactions, which are partially dissolved by heat, to reappear again when the solution becomes cold. The addition of strong acetic acid to the diluted urine yields the mucin reaction, as does also Almen's tannin test used in conjunction with saturated salt solution. In short, the reactions produced by the presence of seminal elements in the urine very closely resemble those produced by serum albumin and may easily cause confusion.

93. **Salt Solution in Surgery, Etc.**—Wallace notices the conditions in which he has found good results follow the use of salt solution, in enemas one to three times a day, such as in typhoid fever, summer diarrhea, abortion, premature birth, appendicitis, alcoholism, abdominal operations, shock, scantiness of urine, acute peritonitis, etc.

94. **Prostatectomy.**—Lydston believes that prostatic overgrowth in any case warrants the consideration of the radical operation. He *classifies the cases* into those beyond middle life where the bladder and kidneys are yet normal; the same complicated by septic vesical inflammation or by secondary renal disturbance; patients from 55 to 65 in whom no secondary conditions have yet occurred; the same cases where catheter life has been established and infection *of the* bladder has occurred *and the kidney has been infected*; patients above 65 with *sound bladder and* kidneys and those where these organs are *involved*; cases in very advanced life in which the patient is suffering, and more or less secondary involvement of the urinary organs exists, and lastly, cases in apparently young subjects with sound bladder and kidneys. *These should be operated irrespective of the severity of the* symptoms. The *only exception* is where the symptoms are slight and the en*largement is simply* of a hyperplasic nature, and the progress of the disease can be checked by other measures. In young subjects with more or less secondary renal disturbance, with or without vesical sepsis, operation after proper preparation offers a favorable prognosis unless secondary renal disturbance is very *marked*. The *mortality*, he thinks, increases with age. Patients above 75 years of age, however, where vesical and prostatic symptoms have become manifest, should be offered the benefit of palliative measures. In a general way patients with sound bladder and kidneys from 65 to 75 years of age afford very favorable prognosis, provided the perineal operation is practicable. In very old patients with severe vesical and *kidney involvement* radical operations are usually contraindicated. The fact that these are the cases that have been usually operated on explains the discouraging results that have been observed. He remarks that prostatectomy of any variety is a misnomer. We only shell out the bulk of the tissue comprising the tumor and a certain amount of secondary in*flammatory intra- and extra-capsular* tissue is left behind, and *nature takes care of it. Total prostatectomy* is *not* practicable within limits of safety, and is unnecessary. Lydston's practice is to operate through the perineum if practicable, but under certain circumstances, the combined or suprapubic operation is often imperative. He illustrates the retractor, which he has found satisfactory, and gives the details of the operation, using the *inverted* Y-shaped *incision* and blunt dissection along the urethra to the apex of the prostate. Where the urethra can be drained he endeavors to do so unless the condition of the bladder is such as requires drainage; and even then a retained catheter may sometimes be used. Where the tumors are polypoid or situated very high up and are distinctly *intravesical*, the combined suprapubic and perineal operation may be required. He distends the bladder with either sterile water or weak antiseptic solutions, after thorough antiseptic irrigation. The question of air vs. fluid distention is a matter of taste. For drainage he prefers a large rigid tube, though in some cases he has used a large rubber tube. The duration of the drainage should be governed by the condition of the bladder.

97. **Arteriosclerosis.**—Elliott considers that the lesions are toxemic in character. The arterial thickening is a conservative process and not the cause of the disease. The symptoms are generally those of high arterial tension. He speaks of the value of the second aortic sound as a diagnostic sign. *As far* as treatment is concerned much can be done. The idea is first the early elimination of the toxemia and the reduction of the blood pressure. The habits of life should be thoroughly overhauled, the diet regulated and hygienic conditions generally made most favorable for normal metabolism. Overwork and mental exertion should be avoided. Medical *treatment* should be directed to reducing the blood pressure, and for this purpose nitroglycerin and the iodids appear to be of the greatest value. While the outlook is unfavorable much can often be done toward arresting the progress of the disease.

98. **Surgical Kidney.**—Harris emphasizes the *importance* of examining the urine from each kidney *separately*, and says

that with his segregator he has obtained in suitable cases very gratifying and reliable results.

11 Abstract of a Report on a Recent Outbreak of Illness Due to Milk. Henry Kenwood.

1. Carcinoma of the Esophagus.—This case, which is carefully reported by Hewetson and Saundby, is of interest especially as being an exception to Semon's law of the early implication of the abductor laryngeal muscles. The law is stated as follows:

> The occurrence of isolated paralysis of the abductor filaments of the recurrent laryngeal nerve in cases in which the roots or the trunks of the spinal accessory, pneumogastric and recurrent nerves are injured or diseased, is not an isolated pathologic curiosity. There is a distinct proclivity of the abductor fibers to become affected in such cases either at an earlier period than the abductor fibers or even exclusively.

In the case here reported the adductors were distinctly involved while the abductors appeared to act well until a few days before death. Both physiologically and pathologically the adductor displacement was earlier and more intense than that of the abductors.

9. Increase of Insanity and Nerve Diseases.—Rhodes uses statistics to show that the prevalent notion as to the increase of nervous disease and insanity is not entirely correct. He points out that while general paralysis, insanity, paraplegia and some other diseases of the nervous system seem to be on the increase still others, reported under the names of softening of the brain, epilepsy, etc., have markedly decreased within the past ten years. He thinks the figures make it almost questionable if there is an increase in nervous troubles, but still some, admitting this, assert that there is a terrible increase in insanity. He takes up this question and finds that the total number of insane has risen markedly and that the low recovery rate under better care casts a burden on the tax payers. The most potent of the changing conditions in producing insanity is the crowding of the population into towns and with that crowding has come the increase of rents, making housing a serious matter to the poorer classes. The confidence of the public in the state care has gradually increased and the visible cases of insanity are consequently more numerous.

12. **Cancer of the Breast.**—Cheyne advocates the complete operation in cancer of the breast, clearing out the lymphatic glands and vessels in the axilla and removing all skin over the prominent part of the breast, and if the cancer is laterally situated, the skin incision should nowhere approach the cancer closer than a couple of inches. The question as to whether the glands in the posterior triangle of the neck should also be removed in all cases is mentioned and he has become inclined to clear the supraclavicular space more than formerly and take out the fat and glands of the lower neck. Any marked enlargement of the supraclavicular glands in his opinion makes the case an inoperable one. He goes into the figures in his own experience; he has had 34 private patients that he was able to keep track of to some extent. In these cases from 6 to 13 years have elapsed since the operation; 17 of these 34 cases are still alive and well, without recurrence. In 14 cases recurrence has taken place and 11 of these have died from the disease; 2 patients have died of other troubles, one without any recurrence 2 years later, and the other 7 years after operation. One case has been lost sight of. The figures, therefore, show that from 50 to 55 per cent. of the cases are alive and well after periods ranging from 6 to 13 years. If these cases had been selected ones he would probably have excluded 11 of them; 2 of these, indeed, were practically hopeless from the start. Nevertheless, of these 11 cases, 4 have remained free from the disease, 1 for 10 years, 1 for 9½, 1 for 7½ and 1 for 7 years, the latter dying of heart disease. He analyzes the cases according to the rapidity of growth, the extent of the disease and the appearance of recurrence, etc., and holds that if the deposits are not cut into at the time of operation and removal is sufficiently extensive, the chances are that at least 50 per cent. of the cases will recover. Cancer is a very local disease in its commencement. If all that exists of it can be gotten rid of, there is no reason to expect a recurrence.

13. **Muscular Structures of the Heart.**—Keith continues his lecture on the muscular structures of the heart as relating to function, showing the manner in which the valves are rendered competent and orifices closed. He thinks we should restore to some extent the former relationship between the anatomy and physiology, for no description of the anatomy of the heart can be considered satisfactory unless it shows the meaning of the structure of the organ.

14.—This article appeared elsewhere. See The Journal of March 12, ¶17, p. 741.

16. **Scarlatina.**—Lauder holds that infection in this disorder is due to throat involvement and not to desquamation. In the Southampton Fever Hospital the patient is examined and a swab taken from the throat for bacteriologic examination; doubtful cases are put in the observation ward and detained or sent home, according to the diagnosis, the ward being disinfected immediately after their removal. Typical cases of scarlatina are put into the "acute room" and kept there until the acute stage is past and diphtheria is excluded. They are then removed to the general ward, where recent cases are kept apart from the convalescent ones. This is done with the mild as well as with the severest forms. If at any time aural or nasal discharges, enlarged tonsils, glands, etc., develop, the patient is moved from the general ward to a special pavilion reserved for such complications. At the end of the third week, if free from complications, the patients are transferred from the general ward to another pavilion which has been thoroughly disinfected and to which no cases are admitted except through the out-bathing station with the same precautions as if they were discharged from the hospital. They are kept here for one week, apart from all the other patients, and the nose, throat and ears carefully douched with a disinfectant each evening after bathing. At the end of a week—that is, at the end of the fourth week of the disease—they are sent home after passing the out-bathing station, without regard as to whether they are still peeling or not. After they are discharged no patients are admitted into the same pavilion until it has been thoroughly disinfected. The general wards are thoroughly disinfected at least once a month. These methods have not only freed them from the occurrence of albuminuria, enlarged glands, discharges of the nose and ears, but have reduced the duration of the fever and the periods which the patient had to be kept in bed and left them during the year without a single case of post-scarlatinal diphtheria or relapse. He gives a tabulated analysis of cases and brief accounts of a few.

17. **Cobra Poison.**—This research was undertaken by Major Elliot to ascertain the precise part played by the action of the poison on the various important centers and organs. A condensed summary of his conclusions is here given: 1. Cobra venom acts directly on the muscle tissue of the blood vessels or through their vasomotor nerve endings, contracting the arterioles and raising the blood pressure and in frog vessels the action can be traced down to a dilution of 1 in 10,000,000. 2. Cobra venom also acts on the isolated frog ventricle, killing in it a position of firm systole if the solution is concentrated and stimulating it if a weak strength is employed. The limit of the speedy lethal action on the isolated heart is reached at a concentration of about 1 in 500,000 and the stimulating action can be traced down to at least 1 in 10,000,000. This action brings cobra venom into the line of glucosids of the strophanthin group, though its action is much more rapid. Atropin sulphate intensifies the action of cobra venom. 3. Cobra venom powerfully affects the isolated mammalian heart when the solutions are introduced through the coronary circulation. The actions seem to be two; one, directly on the heart muscle and nerve endings, and the other on the intracardiac vagal mechanism which makes for inhibition. The result is that with a strong solution we find irregularity and extreme excitement of the heart followed by early death in systole, and with lesser concentration this yields to a prolonged phase in which the tonic action of the poison on the heart is pronounced. Cobra venom interferes with the circulation through the heart in a marked manner, probably through contraction of the coronary vessels and a condition of tonus. 4. In low lethal dose cobra kills by paralyzing the respiratory center. This is gradually evolved and there is evidence of heart stimulation preceding the paresis as greatly increasing the venosity of the blood and slow asphyxiation. If the life is prolonged by artificial respiration and if the dose is very small, the phrenic and other motor nerve endings may become paralyzed. The convulsions preceding death are purely asphyxial and each is followed by a phase of exhaustion of the respiratory mechanism which is almost certainly central. If a large dose is given the respiration is quickly affected and may cease at once, and the patient dies if artificial respiration is not quickly resorted to. With a smaller dose the rhythmic activity of the center reasserts itself, but it ultimately fails. By applying cobra venom directly to the exposed medulla of a rabbit Elliot found that the respiratory center may be paralyzed without the phrenic nerve ends of the heart being appreciably affected. If very large doses are injected death may occur by cardiac failure before the respiratory mechanism gives way. 5. Cobra venom in low lethal doses subcutaneously raises the general blood pressure, but the drug acts on the muscle tissue of the vessels and increases the force of the heart beat and stimulates the vasomotor center. The late fall in the heart beat is due to cardiac inhibition caused by gradual

asphyxiation and the direct stimulating action on the vagal inhibiting center, and probably also by stimulation of the vagal nerve ends by the circulating venom. It is probable that a stage of exhaustion of the heart muscle follows early stimulation and the exhaustion of the heart is probably produced by the strain of having to work against the abnormally high blood pressure. 6. When injected in large doses and given intravenously there is a sudden fall of the blood pressure and a subsequent rise, provided the dose has not been too large, and a final fall to zero. The early fall is undoubtedly due to inhibition. 7. When the secondary rise of blood pressure following the primary fall occurs it is due to the same factors which caused its occurrence when the small dose was injected. It is merely a question of cardiac failure. The direct inhibitory action of the venom through the vagal center is capable of overcoming the tendency which the blood circulating through the heart muscle has to throw that muscle into death in systole. If it were not for these two rival forces cobra poisoning would kill by its direct action on the heart muscle. When the dose is very large the direct muscle stimulation may be so intense as to overcome the maximum inhibitory impulse and the heart dies in systole with a quickened beat and is found after death as hard as a contracted postpartum uterus.

19. **Ichthyol Compounds.**—Ichthyol is a hydrocarbon oil obtained from a fossiliferous mineral and this, after being acted on by sulphuric acid, gives us ichthyol-sulphonic acid. It is the ammonia salt of this acid which is known commercially as ichthyol. Burnet reviews the various compounds and their substitutes: 1. Iron-ichthyol or ferrichthol, a brownish-black amorphous powder, odorless and tasteless, which has been very useful in his hands, in some cases when other iron preparations could not be tolerated. He thinks it is an excellent remedy in secondary anemia. In chlorosis he has, however, seen no good follow its persistent employment. He thinks the action of iron is greatly aided by the presence of ichthyol and that it has a wide sphere of therapeutic application in all its combinations associated with anemia. His own observation of its value in general diseases are borne out by Unna in regard to dermatologic conditions. Sodium-ichthyol is a solid preparation which is not so active in pulmonary disease as the original ammonia salt, though more easily taken. It checks the fermentative processes in chronic gastric catarrh. Generally speaking, when ichthyol is indicated, this should be prescribed except in case of pulmonary disease. Calcium-ichthyol is well suited for use in dermatologic practic and is readily taken by children. Within the last few years ichthyol has been made use of as a vehicle for certain insoluble agents such as cresol, eucalyptol and even iodin. Out of all the preparations he thinks two stand forth pre-eminently, viz., ichthoform and ichthargan, the former being a compound of ichthyol with formic aldehyd and the latter a silver salt of ichthyol. He finds ichthoform of value as an intestinal astringent and antiseptic, in summer diarrheas of children, etc. It is not poisonous and can be given in doses ranging from 2 to 10 grains three times a day. He prefers to give it as a sandwich between bread and butter. He thinks rectal administration should also be tried. Polacco has used it in enteric fever in doses of .5 gram frequently repeated, with good results. As a dusting powder in varicose ulcer he has found it of special benefit and for foul ulcers he knows no more trustworthy remedy. With equal parts of boracic acid it will be found serviceable as a dusting powder for general use. It is also of special value as an ingredient in ointments and he has suggested its use in the form of ichthoform gauze as a substitute for iodoform gauze for packing cavities. He says it is one of the most efficacious antiseptics we at present possess, especially in cases of intestinal disease where its action is most certain, is more certain and less harmful than salol or similar substances and is an excellent substitute for iodoform where the latter is indicated, is odorless and markedly nontoxic. For internal administration it is best given in small doses frequently repeated. His experience with ichthargan has not been so extensive as with ichthoform, but he speaks of its value in gonorrheal urethritis, gynecologic affections, dermatologic practice and nose and throat disorders. He says it is the remedy par excellence in atrophic rhinitis. It may be safely given internally in a mixture of from 0.5 to 2 grains in 8 ounces of water, of which a teaspoonful is taken three or four times a day. It seems to be useful in promoting healing in gastric ulcer and has been recommended by various observers in eye diseases; in ointments for skin disorders he has found it of very great use.

21. **Diagnosis of Typhoid.**—The early diagnosis of typhoid is often impossible, and medical aid is seldom called in until the case is somewhat advanced. Ker notes the appearance and facial expression, which are suggestive; the slight hectic flush and widely dilated pupils are often observed during the first fortnight. The gradual rise of temperature is a point of interest, also dicrotism of the pulse and a lower rate than would be expected from the high temperature. This combination should always suggest typhoid. Again during the early period it is unusual to find the respiration very frequent, and if above 28 or 30 in the adult we should suspect pulmonary disease in preference to typhoid. Tumidity of the abdomen is so much the rule that a case of flat or hollow abdomen is usually not typhoid. The value of gurgling is overrated. The main point is the recognition of the spots. They are not seen in half the hospital cases, but in many instances it is probable that they have been present previous to admission. Their absence is of no value in diagnosis, though their presence is typical and practically final, and the presence of even atypical spots is of considerable value in the diagnosis. The presence of slight bronchitis or bronchial catarrh has not been duly estimated. A case of continued fever without definite symptoms, but with a slight degree of bronchitis, is very probably typhoid. The list of diseases which may be mistaken for typhoid is very large, and the chest should be thoroughly examined before the diagnosis is made, to exclude pneumonia and tuberculosis. Some cases of tubercular meningitis may give trouble, and, in the early stages, tubercular peritonitis. Colon bacillus infections are also mentioned as producing difficulty, but these cases should be treated the same as enteric. The diazo-reaction is found in other conditions, and its chief value is rather in its absence than in its presence. A case of continued fever not giving this reaction between the sixth and twelfth days is in all probability not typhoid. The leucocyte count in typhoid is low, the multinuclear cells are diminished in percentage and the uninuclears are increased, while the eosinophiles are few. The blood changes, however, are of only limited value in the diagnosis. The isolation of the bacillus and the serum reaction tests are the real final proofs. It is well to inquire, however, whether the patient was ever vaccinated against typhoid or has had typhoid previously. A negative Widal reaction in the first fortnight means little, but if still negative in the third week is strong presumptive evidence against enteric fever. After three weeks a negative reaction practically excludes the disease.

22. **Antityphoid Inoculation.**—Wright gives the technic, dosage, symptoms and results. He advises two consecutive inoculations adjusted to avoid the supervention of constitutional symptoms rather than one severe one. He points out the fallacies and errors that may occur and gives elaborate tables. He thinks that undoubtedly a reduction in the incidence of typhoid fever was achieved in S. Africa, varying from six-fold to twenty-eight fold and a striking diminution in the mortality. The death rate among the inoculated was comparatively small. As regards the duration of the protection, it

appears that it may exert a protective effect for two years after the inoculation.

23. **Black Urine.**—The various conditions which may cause a dark-colored urine, including jaundice, hematuria, hemoglobinuria, hematoporphyrinuria, melanotic sarcoma, alkaptonuria, ochronosis and various drug effects are described by Garrod. True melanuria associated with melanotic sarcoma is rare. One must be acquainted with all the conditions and the means of distinguishing one from another before one can estimate their diagnostic importance. This is also still more true as regards prognosis, as whereas the occurrence of true melanuria is an event of the worst omen, as indicating the recurrence of melanotic growths in the viscera, there is an equal degree of blackness in alkaptonuria, which, so far as we know, is harmless. Between these extremes are various conditions of differing degrees of gravity.

33. **Diagnostic Value of Myelemia.**—Contrary to what is observed in experimental research, in man no acute affection, with the exception of purpura and smallpox, determines decided myelemia. Leukemia and allied conditions constantly determine a myeloid reaction in both the blood-forming organs and the blood, but while in leukemia and certain cases of splenomegalia the myeloid hyperplasia resembles that of malignant growths by its exuberance and generalization, in typical pernicious anemia the process seems to be limited to a rejuvenation, a simple metaplasia. Besides these, there is only Biermer's disease which is accompanied by myelemia. The diagnostic value of myelemia is, therefore, most marked in smallpox, and it frequently allows the rash to be promptly differentiated from measles, scarlet fever and atypical syphilis. The myelemia does not always occur at an early stage, but when vesiculation commences it seems to be constant, and is always intense in comparison with the attenuated and inconstant myelemia observed in the purpuras. Myelemia is also extremely important for the differentiation of splenomegalia, accompanied by myelemia, which seems to be particularly malignant in the adult. The various forms of myelemia and the affections in which it is noted are carefully studied under the headings of leukemic myelemia, aleukemic myelemia and myelemia in acute or subacute infections. The authors protest against the term "pseudoleukemia" as being incorrect—there are no false diseases.

34. **Inherited Syphilis.**—Boissard comments on the fact which seems to be established that when a woman has once borne a child to a syphilitic all her children born afterward are liable to bear some syphilitic taint, although she may never have had but the one intercourse with a syphilitic, and the father of her other children may be sound. In his experience at Tenon Hospital he has frequently observed infants who seemed decrepit, arrested in their development, "without aptitude for life." Their curves of growth remain horizontal instead of rising, and this notwithstanding that the children are always hungry and crave more than the standard quantity of milk for their weight. Little dependence can be placed on the mother's statements, but her obstetrical past may suggest inherited syphilis, and the way in which the children thrive on mercury proves that it is needed. He gives it in the form of van Swieten's solution, twenty to sixty drops or even more, his experience demonstrating that newly born infants bear mercury remarkably well, probably on account of the good kidney elimination and the absence of teeth. He usually gives the mercury for twenty days at a time, with ten-day intermissions. He insists that this mercurial treatment must be kept up for several years, with intervals of suspension; returning to it whenever the child shows any arrest in its development in any way. He thinks that many instances of abortions or sterility may be due to unrecognized inherited syphilis, that is, to the syphilis of the grandparents.

35. **Therapeutic Action of Induced Leucocytosis.**—Ramond reports the results of research undertaken under the direction of Chantemesse. They show that the leucocytes which gather under the influence of the measures taken to induce hyperleucocytosis are destroyed by the action of these measures. New leucocytes take their place, but they are too immature to display phagocytic action, and acquire it only after a certain length of time. Consequently the induced hyperleucocytosis is in reality merely the destruction of the reserves of leucocytes which the organism has been keeping on hand in readiness for emergencies. The simultaneous injection of microbes and of the substance destined to induce hyperleucocytosis accomplishes better its purpose as the gathering leucocytes are able to deal with the pathogenic agents at once. But in the clinic, the physician is not summoned until the infection is already established, and hence can never take advantage of this phenomenon.

36. **Formaldehyd for Disinfection of Carious Teeth.**—André lauds a combination of formaldehyd and essence of geranium as the most powerful disinfectant and deodorizer known, while it does not injure the teeth in any way. His formula is 4 parts formaldehyd and 2 parts redistilled essence of geranium in 4 parts of 80 per cent. alcohol.

38. **Serum Therapy of Cancer.**—Doyen isolates from neoplasms of rapid growth a microbe to which he gives the name of *Micrococcus neoformans*. He described it in 1901, and he has been experimenting with vaccines and toxins derived from it. He has thus treated 126 cases and reports 21 as cured, 47 improved and still under observation, and negative results in 58. He states that eight months of cultivation are required for the production of a powerful toxin. The culture medium which he prefers is a peptonized bouillon made from cow's udders.

40. **Atheroma Due to Suprarenal Capsules.**—Josué suggested that arterial atheroma might be due to the suprarenals when he observed the high arterial tension which is induced by injection of suprarenalin and adrenalin. This theoretical assumption was corroborated by experimental research, and he now announces that the necropsy of three subjects with arterial atheroma still further confirms it. All three exhibited the anatomic evidences of hyperfunction of the suprarenal capsules.

51 *Le salicylate de soude dans le traitement de la chorée d'origine non rhumatismale. Zaoussailov. Abstract.

42. **Tendon Suturing.**—Lejars illustrates a modification of the latest methods of suturing a severed tendon, which he thinks is more solid and less liable to pull out than any yet proposed. The needle is passed back and forth through the tendon stump to make a cross, each arm of which consists of

two parallel lines of thread. The ends of the thread are then tied around the stump of the tendon and the two stumps are approximated and tied together by these threads, supplemented by a few sutures at the edge of the stumps.

44. **N Rays in Nervous Affections.**—Ballet has found that there is less emission of the N rays in affections involving the peripheral motor neuron, such as paralysis or atrophy resulting from myopathy, neuritis or poliomyelitis. On the other hand, in affections involving the motor protoneuron, such as old hemiplegia with contracture, or spasmodic paraplegia, the emission of N rays is more marked from the paralyzed muscles than from their sound mates.

49. **Radium Treatment of Cancer of the Esophagus.**—Exner has treated 6 cases of cancerous stricture of the esophagus by introducing a scrap of radium embedded in dammar and fastened to a No. 16 sound. In 5 cases the stricture became enlarged and the dilatation persisted after the treatment was suspended. The increased permeability of the stricture is probably due to necrosis of the stricture tissue under the influence of the radium, and it thus gives permanent results.

50. **Retrorectal Injections of Salt Solution to Cure Incontinence.**—Jaboulay injects about 100 gm. of physiologic salt solution into the cellular tissue behind the rectum as a means of acting directly on the hypogastric plexus. The needle of a Roux syringe is inserted at the tip of the coccyx or to one side. No anesthesia is required. If one injection is not enough he repeats it two or more times and increases the amount. Incontinence of urine rebellious to all other measures was cured by two to four of these injections. The subjects were young women. In one case the amount injected was doubled at the two final injections before a cure was realized.

51. **Salicylate of Soda in Chorea.**—In 4 cases which had resisted arsenic, iron, bromid, etc., the children were promptly cured by a systematic course of salicylate of soda, although not a single feature of the cases suggested rheumatism or heart complications.

52. **Action of Galvanic Current on Tetanus Toxin and Antitoxin.**—Von Behring and Römer announce that application of a weak galvanic current increases the toxicity of a solution of tetanus toxin and reactivates an inert one. The toxicity of the fluid which accumulates at the cathode varies from that at the anode, and other paradoxical facts were noted, among them the phenomenon that sometimes a mixture of tetanus toxin and antitoxin proves more toxic when inoculated into small laboratory animals than a larger dose of the same mixture. The concentrated mixture proved harmless, while the tenth and fortieth dilution induced acute and fatal tetanus, and even the hundredth dilution killed a mouse. Behring regards as fundamentally important the findings of these experiments that the toxic action of the tetanus toxin molecule in a colloidal solution can be enhanced by conducting a weak current through it. Further experiments with other colloid solutions are in progress, and those with milk protein molecules are proving interesting. A whey free from casein is obtained from fresh milk and displays considerable bactericidal action in respect to the colon bacillus. When a 1 ampere current is conducted through this whey for ten minutes this antibacterial energy is found much more intense in the fluid collected near the anode, while it is much diminished at the cathode. Ultramicroscopic examination also showed that 2,000 molecules were visible in the fluid at the anode while only 25 could be discovered at the cathode and 1,000 in the intervening fluid. Whey not submitted to the electricity presented an average of 100 molecules in the field at each inspection anywhere in the fluid. Similar research on an anti-colon bacillus horse-serum, which showed about 50,000 molecules to the field beforehand, after a current of 1 ampere had been passed through it for fifteen minutes exhibited extremely intense bactericidal action and 400,000 visible molecules in the fluid near the cathode, with only 7,000 at the anode.

53. **Bactericidal Reaction in Serum of Typhoid Patients.**—Stern and Korte advocate tests of the bactericidal action of the serum as a more delicate diagnostic measure than agglutination. Less than half an hour is required for it, and the results are manifest in eight hours, or at most by the next morning. The principle of the test is the addition of the suspected serum to a combination of fresh normal serum and typhoid bacilli. By constantly reducing the amount it is possible to determine the smallest proportion which still displays bactericidal action. The suspected serum is heated to 56 C. to render the complement inactive, and is placed in a row of test tubes, diluted to 50, 100, 1,000-fold or more with .85 per cent. salt solution. The tubes are filled in turn with one-half, one-fourth, one-eighth, etc., of the original dilution and then filled to 1 c.c. with the saline. Then .5 c.c. of a 1/5,000 twenty-four hours' bouillon culture of typhoid bacilli is added to each tube, and also .5 c.c. of fresh rabbit serum diluted 10 or 15-fold with .85 per cent. salt solution. Each tube then contains 2 c.c. of fluid and the bacilli, with graduated proportions of the suspected serum. The set of tubes is then placed in the incubator and after three or four hours the contents are poured out on agar plates. These are kept for twelve hours in the incubator at the same temperature (37 C.), or the test can be limited to mere inspection of the tubes after eight hours in the incubator. In the controls, 35,000 colonies and more developed, while with dilutions of 1/2,000 to 1/16,000 none developed with the typhoid serum, and only 100 to 1,000 colonies in the dilutions above this to 1/256,000. The bactericidal action was still marked in a dilution of 1/4,096,000. The writers think that this method is destined to supplement the agglutination test in dubious cases and possibly supplant it where an early diagnosis is necessary. They had no opportunity to test any patients before the eighth day.

54. **Physical Chemistry and Serum Therapy.**—[Arrhenius is the noted Swedish physical chemist to whom one of the Nobel prizes was recently awarded. The importance of his physicochemical work and its results were set forth in an editorial in The Journal of March 5.] He here discusses Ehrlich's recent study of diphtheria toxin, published in the *Berliner klinische Wochenschrift*, Nos. 35 to 37, disagreeing with him on certain points, but extolling as "one of the many things for which Ehrlich is most to be praised, that he has always proclaimed that (physical and) chemical processes are concerned in the reactions between toxins and antitoxins as between bodies and antibodies in general." He comments with especial appreciation on Ehrlich's remark that scientific research should restrict itself first to the simplest explanatory possibilities, and not call on more complicated ones until the simple ones have been shown to be inadequate.

60. **Tuberculosis Dispensary at** *Berlin.*—Jacob reviews the work accomplished by this new institution during the four months since its foundation. It has already proved its great usefulness as a link in the chain of compulsory insurance of the working classes against sickness. Tuberculous subjects are diagnosed, watched over, contagion of others guarded against, and more favorable surroundings provided. The dispensary aims to do nothing which it is the right and duty of others to do, but to supplement and complete wherever the aid of others proves inadequate. Various charitable organizations co-operate with it.

62. **Paraffin Prothesis in Ozena.**—Fliess reports 12 cases of ozena treated by local injection of hard paraffin. The results far surpassed those obtained by other modes of treatment, and most of the patients are completely cured and the others so improved as to amount to a practical cure. All had been for years treated by various specialists with the usual insuccess. During the total of 32 injections no disturbances were noted in any instance. No mishaps have been reported from the use of hard paraffin.

63. **Improved Jejunostomy.**—Kelling produces a jejunum fistula which closes water-tight, even during coughing, etc. He has applied it on 8 patients with highly satisfactory results, the survival being for several months, the longest being nine months and ten days. There was an inoperable cancer in each case, and under these circumstances the simplicity of the technic is not so important as the water-tight closure of the opening, and this was unfailingly realized. The special feature of the technic is that the projecting end of the stump of the intestine is tied and turned back inside, thus invaginated for about 5 cm. The drain is a 6 mm. Nélaton catheter, which passes through a small opening near the tip of the invaginatum. The upper, folding over end of the stump does not project beyond the inner layer of the abdominal wall, where it is sutured tight around the catheter.

64. **Artificial Biliary Passage.**—Krukenberg's patient was a debilitated man of 78, with severe icterus, commencing cholemia and other signs of cholelithiasis. The gall bladder was found filled with gravel and thick bile. It was evacuated, twisted 270 degrees on its longitudinal axis and thus transformed into a spirally wound passage similar to a normal cystic duct. It was fastened in this position with six fine sutures, and the fundus was implanted in the jejunum in such a way that it projected like a tuft into the lumen of the latter. The fever dropped at once, and in less than two weeks the icterus and liver tumor had entirely vanished and the patient has been freed from disturbances since the operation, which was undertaken last September. The prompt and durable benefit indicates that this mode of intervention is less serious than an operation on the common bile duct would have been. It is possible only when the gall bladder is large and elastic enough to be thus transplanted, and this can be determined beforehand.

65. **To Eliminate Pneumothorax in Intrathoracic Operations.**—Sauerbruch has constructed an air chamber in which operations may be performed on the thorax without interfering with respiration. It has proved perfectly successful on animals, and has allowed all kinds of operations to be performed inside the thorax without fear of pneumothorax. It aims to exclude entirely all atmospheric pressure during the intervention. When the atmospheric pressure is eliminated, the lungs do not collapse when they are opened to the air and the respiration proceeds normally. He found that he could open the thorax on both sides and even remove all the sternum and ribs, leaving merely small stumps, and all without interfering with the normal respiration of the animal, which continued unmodified as long as the atmospheric pressure was eliminated from its environment. The chamber which he has constructed is air-tight and large enough to admit the operator and assistant, the operating table and the body of the animal. The animal's head projects outside, a rubber cuff fitting tight around his neck. The air-pressure is regulated by an air-pump, while a valve in the wall allows air to enter just enough to maintain a constant negative pressure in the chamber. The operators did not experience any ill effects from remaining in this chamber. Mikulicz and an assistant worked in it one day for an hour without discomfort, except from the warmth and moisture, which would be obviated by construction of a larger chamber. The one now in use is about 40x45x55 inches. It is made of boards, lined with tin, soldered at the corners, the entire top of glass. Sauerbruch is now preparing a monograph on the physiologic principles of this exclusion of atmospheric pressure as an aid for operating on the thorax, and intends to report in it his clinical experience to date of writing.

68. *Aseptic Introduction of Catheter.*—Swiatecki holds the catheter by the handle and lubricates it with a pair of long gynecologic forceps. He then seizes the end of the catheter near the tip, with the points of the catheter blades, and holds both forceps and the large end of the catheter in the right hand. The catheter thus is bent in the shape of a C, and when the forceps holds it near the tip the outline is like that of a D. This gives sufficient purchase on the catheter tip for it to be easily inserted in the meatus with the right hand alone, and the fingers have not touched the catheter at any point except near the handle where contamination does no harm.

69. **Infrapubic Prostatotomy.**—Heusner resected the lower half of the symphysis and the descending rami of the pubis to obtain access to the prostate in the case described. He has since established by experiments on the cadaver that it is possible to detach the prostate from the pubis and draw it entirely down below the pubis without resection of bone.

71. **Trephining Under Local Anesthesia.**—Heidenhain's experience with 2 cases in which trephining was performed without general anesthesia or any loss of blood, has been so favorable that he advocates his technic as an improvement over previous methods. He believes that even major operations on the skull can be safely undertaken with the combination of cocain and adrenalin which Braun recommends. To prevent bleeding from the galea Heidenhain commends his practice of taking a series of overlapping stitches with a single thread, on each side of the proposed incision. By pulling the ends of the thread the tissues are compressed and no bleeding can occur after the incision is made. If a little blood still escapes a ligature can be applied here and there. It is important to leave these threads in place and not remove them for eight to ten days. The needle should be semicircular, medium sized, and scrape along the bone as far as possible for each stitch. They should overlap half the length of the preceding stitch.

77. **Popular Science.**—Burckhard quotes extensively from two books on household medicine by a practicing woman physician in Dresden, to show the dangers from such popularly written works, evidencing such superficial knowledge, prejudice and lack of common sense. Among other points which he cites is its warning against mercury in syphilis, and its recommendation of a method of treating peritonitis which would be practically murder if carried out. He remarks that the most ardent advocate of opening the medical career to women would be silenced by a reading of this work, which is the production of a graduate woman physician whose name and titles he gives in detail. He also quotes from another work by a "nature doctor," which is now in its three hundredth thousand, to the effect that cancer can be cured by the non-surgical measures advocated. The sale of this book has been prohibited in Austria, but it is sold largely elsewhere.

81. **Hyperemesis Gravidarum.**—Oehlschlager ascribes the vomiting in pregnancy to an oversecretion of gastric juice in the stomach, induced by irritation of the innervation from the unaccustomed movements of the uterus substance. For fifty years he has been treating such patients by correcting the hyperacidity with bicarbonate and soothing the nerves with strychnin. Every two or three hours he gives a tablespoonful of the following mixture, and has never had a case that failed to respond promptly. His formula is 8 gm. sodium bicarbonate, 3 gm. tincture strychniæ; 150 gm. distilled water and 30 gm. syr. cinnam. If he should happen to encounter a case rebellious to this medication he would induce abortion by injection of 3 gm. tincture of iodin in the uterus. He has long been convinced of the benefits of intrauterine injections of tincture of iodin in case of general sepsis of the uterus, such as occurs after delivery and operations on the uterus.

86. **Yeast in Treatment of Gonorrhea in the Female.**—Abraham comments on the harmonious results of his bacteriologic and clinical experiences with yeast and gonococcus infection.

87. **Possible Danger from Lumbar Puncture.**—Mathes' patient was a woman of 52, who was being operated on for carcinoma of the portio. The uterus was removed *in toto* according to Schuchardt. An attempt to induce spinal anesthesia was unsuccessful. The trocar entered deep enough, but no fluid escaped, except a drop of blood. The next day symptoms of meningitis developed and progressed to a fatal termination in five days. The necropsy revealed an aneurism of the left vertebral artery, with compression of the brain and medulla. The aneurism had perforated, and there had been much hemorrhage. The question then arose as to whether the lumbar puncture might not have contributed to the rupture of the aneurism, and if any fluid had been evacuated this might have seemed probable, but the evidence was against it in this case. It suggests, however, that lumbar puncture under similar circumstances in another case might possibly entail the rupture of an aneurism.

89. **Eserin in Post-Operative Paralysis of Intestines.**—Arndt describes 5 cases out of a large experience to demonstrate the life-saving efficacy of eserin in these circumstances. He injects 1 mg. of physostigmin (eserin) salicylate, an amount which is perfectly tolerated even by debilitated patients. He never had occasion to give more than 2 mg. in the twenty-four hours. When it does not prove promptly effective he supplements it by repeated lavage of the stomach, as he attributes the persistence of the atony to distension of the stomach, which is particularly liable to follow operations in the Trendelenburg position, and which is not influenced by the eserin.

91. **Extramedian Symphysiotomy.**—*Gigli's extramedian symphysiotomy* has been described in these columns, xl, page 133. In this address, delivered at the Italian Congress of Gynecology last October, he reviews the experiences to date with it. Fifteen women have thus been operated on, and a number were demonstrated to show the complete restitutio ad integrum, with a slightly enlarged pelvis, allowing normal deliveries thereafter.

111 Discussion on Case of Acute Cocain Poisoning Mentioned on Page 863. From society report.

*93. **Shot Wounds and Tetanus.**—Schmidt asks* why wounds from shot are not more often followed by tetanus, as it has been demonstrated that the cartridges almost invariably contain tetanus bacilli. He answers his own question by pointing out that when the missile is fired from a distance the accompanying paper is usually lost on the way, and wounds causing much laceration of tissues from nearby explosions are usually treated in such a way that the tetanus bacillus does not find conditions favorable to its growth. There is peculiar danger from the small wound caused by a particle of shot fired near the part and causing what is supposed to be an insignificant wound. He has observed 2 such cases. A small pocket or bicycler's pistol, loaded with fine shot, went off in the subject's hand, and one piece of the shot made a small wound in the forearm. It rapidly healed, but after a few days symptoms of inflammation developed in the depths and rapidly fatal tetanus followed in both instances. A scrap of cartridge paper was found in the wound in each case. Similar cartridges bought in the market were found almost invariably to contain tetanus germs, as also the raw material obtained from the factory.

97. **Cinnamic Acid in Tuberculosis.**—Brasch has treated 52 patients with Landerer's hetol (cinnamic acid) during the last four years, and his experience has been extremely favorable as he describes in detail. He has made about six thousand injections of the hetol and has never observed the slightest disturbance from its use.

99. **Paratyphoid Fever.**—Clemens reviews sixty articles that have been published bearing on this subject including the American contributions, and draws from them the clinical picture of paratyphoid infection. There is no characteristic feature to differentiate it clinically from typhoid, although cases of apparent typhoid with atypical intestinal symptoms should suggest paratyphoid, and possibly also hemorrhagic cutaneous affections, the dark macular spots differing from the roseola of typhoid.

101. **Sanitary Conditions on Island of Formosa.**—Yamaguchi relates that since Japan acquired this island at the close of the war with China in 1895, numerous sanitary reforms have been instituted. She first had to root out the bands of robbers and pirates and gain a firm political hold over the native races and the large Chinese population. The next step was

to combat the opium evil. The abuse of opium has extended enormously throughout the entire Chinese empire during the last sixty or seventy years. Although the Chinese government has been anxious to check it by legal restrictions, it has never been able to accomplish this as the forbidden drug is imported from England, and the evil is perpetually fostered in this way. The number of persons addicted to opium in the Chinese provinces is about as large as the number of persons in Europe who smoke tobacco. Poor and rich alike are addicted to opium and in the houses of the well-to-do it is served regularly after dinner. As the price is somewhat high the rich use it more than the poor. The Japanese government was, therefore, confronted with a deeply rooted evil, but the happy suggestion was adopted to officially class opium smokers as sick persons, and explicitly designate them as patients. Opium smoking was forbidden to minors, and adults have to obtain an official permit before they can purchase any of the drug. The government also made the production of opium a state monopoly. By these means it was hoped to gradually reduce the number of opium smokers, and the number did drop within a year from the 165,753 official permits issued in 1900 to 156,366 in 1901. Opium used to be prescribed by the local physicians as a panacea against nearly all affections. The Japanese government has sought to counteract this by supplying trained physicians. These physicians reside in districts two or three miles apart. They receive good salaries and, besides their private practice, have charge of medicolegal and sanitary affairs in their district, as well as the care of the poor. The opium smokers must obtain their permits from this district physician, and by so doing constitute themselves his patients and are regarded and treated as patients. There are more than 1,200 Chinese doctors practicing on the island, and a few English missionaries with very primitive medical knowledge. A state examination is now required of all newcomers. There are already 157 trained Japanese physicians on the island, with 11 hospitals erected by the government, the principal one being almost luxuriously fitted up at a cost of a quarter of a million dollars, with trained nurses and attendants. A medical school has been founded in which the natives are educated at the expense of the state after having taken a Japanese preparatory course and passed an official examination. Special attention is paid to experimental work, the students being required to control and confirm the facts taught them in physiology and bacteriology. Yamaguchi adds that Chinese physicians have not the remotest idea of experimental pathology. At first it was difficult to procure anatomic material as the Chinese ancestor worship rendered them superstitious about the dead, and the rumor was spread abroad that the Japanese wanted to get the hearts of dead natives to deliver them to the devil. Years of efforts were required before this tradition could be uprooted, but now there is no lack of anatomic material, utilizing the bodies of criminals and paupers. The Japanese language is taught from the primary schools upward, and the lectures are in this language. The elements of English, German and Latin are also taught in the college to aid in the understanding of technical terms. The graduating class in 1903 numbered 15. A number of students from southern China are enrolled in its membership, as the enlightenment introduced by the Japanese is spreading to the adjacent mainland. Yamaguchi adds in conclusion that sewage and drinking water problems have also been met and solved, harbors built, etc., the drug and midwifery trades reorganized, and that the Japanese government has thus sown all over the land a rich seed from which it hopes to reap a fine harvest in the time to come.

104. **Inoscopy.**—This method of detecting tubercle bacilli in effusions was described in The Journal, xl, page 546. Fourteen cases were tested in the research here described. The signs of tuberculosis were unmistakable and the inoscopy was applied to ascertain its corroborative value. The results were positive in only 4 out of 12 cases and were negative in the 2 cases of ascites.

105. **Antitoxin Treatment of Tetanus.**—Tourneau's experience with the 3 cases reported has convinced him that tetanus antitoxin has no favorable influence when not injected until after the first symptoms of tetanus have developed.

109. **Lactagol for Promoting Lacteal Secretion.**—Mond ordered the preparation of cotton seeds, known as lactagol, for a number of nursing women and found that the secretion of milk materially increased under its influence. His results confirm those mentioned in abstract 80, page 744. The material to date has not been very large, but the results have been so invariably excellent that the writers hasten to advocate the general use of cotton-seed preparations. In the form of oil cake it has thoroughly established its value in dairies.

110. *Anesthesin in Seasickness.*—Schliep has been the medical officer on a ship making transatlantic and other trips, and has had frequent opportunity to appreciate the efficacy of anesthesin as a means for preventing seasickness. Passengers who had been seasick on previous voyages were given three or four powders of anesthesin, each .5 gm., as a prophylactic measure during the first hours after the ship sails, repeating these doses for a few days, according to circumstances. The majority of persons thus treated showed no symptoms of seasickness during the entire trip. It also exerted an unmistakably favorable action when its administration was not commenced until the first manifestations of seasickness developed, the loss of appetite and nausea, but after vomiting was once established and the seasickness well under way the anesthesin was unable to arrest it. Patients at this stage are apt to be too apathetic to be induced to take anything. As anesthesin is comparatively innocent, 2 and 3 gm. can be given during the day with impunity. Its efficacy as a preventive of seasickness confirms what von Noorden has asserted in regard to its value in cases of ulcer of the stomach, nervous dyspepsia, vomitus gravidarum, hyperesthesia of the stomach, etc.

115. **Subcutaneous Albumin Feeding.**—Credé has been for years trying to find a substance that could be utilized for keeping up the strength of patients after operations which forbid temporarily the use of the stomach. He thinks he has accomplished this with a preparation of meat which contains 95 per cent. of easily soluble albumin in a readily assimilated form, with traces of iron, and .2 per cent. salt. The albumin in this preparation, which he calls kalodol, is in a form resembling that of the albumin in the circulation and is assimilated without effort. A person weighing about 125 pounds requires in the neighborhood of 80 gm. albumin a day, but only about a third of this amount when sick, not more than 27 gm. Four subcutaneous injections of the kalodol during the day supply about 20 gm. of albumin, which can be supplemented by more given by rectal injection, absorption of the kalodol from the rectum being remarkably rapid and complete. He has found it a peculiarly beneficial and almost life-saving measure to add 50 gm. of a 10 per cent. kalodol solution to 500 gm. of physiologic solution when the latter was given subcutaneously. By injecting where the skin lies loose on the fascia, injecting under low pressure and delicately stroking away the accumulating fluid, it is possible to avoid any reaction, especially when the amount is injected at two or three separate points. The kalodol is absorbed so rapidly in the rectum that several enemata can be given during the day. It leaves no residue to putrefy in the bowel.

127. **Pathology of the Liver.**—Tischner induced pathologic conditions in the liver by ligating the hepatic artery, occluding the common duct and by intoxication with phosphorus. His researches were conducted on a large number of rabbits. The extensive monograph is illustrated and the findings carefully analyzed.

128. **Alcoholism and Degeneration.**—Bunge has taken the trouble to send question blanks to a number of physicians practicing in Switzerland, Germany, Austria and Russia, Hungary and Turkey, inquiring in regard to the connection between alcoholism in the father and the nursing capacity of the daughters. His comprehensive statistics show that chronic alcohol poisoning in the fathers has a great influence on the daughters in this respect, and also on the resistance of the children to tuberculosis and nervous affections. He received 1,629 carefully filled out blanks in reply. In the total number 1,110 women were unable to nurse their children, and in the 716 cases in which the mother's capacity was mentioned he found that the mother likewise had been unable to nurse her children in 60.8 per cent. With a single exception, the 422 nursing women had mothers who had nursed their children. These figures show the marked hereditary character of the nursing capacity. He classified the statistics in many different ways, but all show the immense influence of alcoholism on the children. One table states that 24.2 per cent. of the children of 103 hard drinkers presented some nervous or mental affection. Tuberculosis was observed in 13.6 of these 103 hard drinkers and in 29.3 per cent. of their children. The proportion of carious teeth was also very high in the children of drinkers. He publishes his question blank and is anxious to collect further statistics in regard to the influence of alcoholism on degeneration.

134. **Tubercle Bacilli in Urine.**—Maragliano's findings were negative in 12 cases. The tubercular lesions were restricted to the respiratory organs.

138. **Prophylaxis of Malaria.**—Mori prefers euchinin to quinin and treated a party of 74 persons with it during the malarial season last year, giving 25 to 50 cg. before breakfast and dinner. Only 6 showed evidences of malaria and 2 of this number had abandoned the use of the euchinin for a week before the first manifestations. The infection yielded rapidly to resumption of the drug. Euchinin does not have the bitter taste of quinin, while it is readily assimilated and has no by-effects even after prolonged dosage. He thinks that possibly the euchinin has an agglutinating action on the erythrocytes.

140. **Vessel Spasms.**—Reale has observed a number of cases of spasm of the vessels and describes two typical examples, due to alimentary or autointoxication.

145. **Vaccination Against Tuberculosis.**—Maragliano has vaccinated a number of children against tuberculosis, the results constantly controlled by experiments on animals. The blood serum gradually acquired agglutinating power up to 1/100, the same as in the animals, and intravenous injection of the animals with virulent cultures of tubercle bacilli demonstrated that they were refractory, completely immune against tubercle infection. He thinks the probabilities are all in favor of the assumption that the children have been rendered similarly immune although confirmation of the test by inoculation is of course out of the question. He proceeds as for smallpox vaccination, and there is a slight febrile reaction the same as in the latter. By what he calls the "progressive" technic he commences with passive and goes on to active immunization. He first injects immunizing substances derived from the blood of immunized animals. This stage is followed by injections of these same substances plus substances derived from the bodies of killed bacilli, a material absolutely incapable of inducing infection. The third and final stage is the injection of products of the tubercle bacilli, also harmless. After a period of three to four months the serum has acquired antitoxic, antibacterial and agglutinating properties. The controls treated step by step in the same way acquire these same properties and prove completely immune to infection with virulent tubercle bacilli. The dead bodies of the bacilli are the chief factor in this vaccination, and the aim is to induce a focus of tubercular inflammation at the periphery entirely free from live tubercle bacilli. From this focus emanate the influences which induce the antitoxic, antibacterial and agglutinating properties, the reaction of defense on the part of the organism. This insures a true and special vaccination. He makes the injection in the arm as for smallpox vaccination. A small amicrobian abscess develops which is slow in healing, sometimes persisting for three or four months before completely healing. His experiences with animals have demonstrated beyond question, he believes, that it is possible to confer immunity by this simple technic. Maragliano adds that his research in this line preceded those of others by six years. Italy also took the lead in the administration of antitoxins by the mouth, as also in vaccinating man against tuber-

culosis. Elsewhere the question is still in the phase of mere hypothesis.

162. **Surgery of the Liver.**—In this comprehensive study of surgical intervention on the liver, Gualdrini emphasizes the value of adrenalin as an adjuvant to tamponing, patching with a piece of omentum or suturing. Injected into the parenchyma it serves to prevent hemorrhage during resection, especially when supplemented by ligature of the larger vessels.

164. **Umbilical Cord in Syphilitic Infants.**—Franceschini extols the advantages derived from histologic examination of the umbilical cord in dubious cases. It may elucidate symptoms and indicate the course of treatment necessary for mother and infant. The syphilitic lesions in the cord are usually restricted to the vessels and these syphilids may precede by months and years any other manifestation of the infection.

180 Another Case of Noma Cured with Pyoctanin. D. T. Akhvledian.—Novii slutchai izletcheniya vodyanogo raka cinim pioktaninom.

172. **Hermophenyl in Syphilis.**—Tchlenoff reports 33 cases of syphilis treated by subcutaneous injections of hermophenyl. It had an unmistakable influence, but less decided than that of mercury, on condylomatous lesions. The local traumatism of the injections is much less than that observed with mercury, and consequently it may be indicated for this reason in certain cases of syphilis.

176. **Pseudo-Chylous Pleuritis.**—The effusion in this case of pleuritis, hydrothorax and ascites was chyliform, but contained lecithin and also cholesterin. The patient was a probable syphilitic.

177. **Surgery of Liver.**—In the 4 cases described all but one of the patients recovered after the surgical intervention on the injured liver. In respect to the diagnosis of such injuries Rozanoff comments that it is rather difficult when there is no external wound to call attention to the special organ injured in the trauma. In his cases the rigidity of the rectus muscles was a striking sign, particularly demonstrative in one case in which rigidity of the left rectus was almost the only indication at first of serious trouble within. Operative intervention is imperative owing to the tendency to severe hemorrhage of wounds in the liver. Shock indicating internal hemorrhage demands immediate operation and hemostasis *in loco.*

178. **Differentiation of Nervous Affections with the "Centrifuge."**—Stein gives illustrations of the "centrifuge" or revolving table and the goniometer or angle-measure which he believes open new horizons for the differentiation of certain nervous affections. The centrifuge is somewhat like an individual merry-go-round. The findings of the tests reveal the greater or less ability of the subject to hold himself in a vertical position. He gives 22 illustrations of the findings on two patients, with 51 various views of the different attitudes assumed by the subjects before, during and after the tests. He is confident that both *otiatrists and neuropathologists* will find this means of investigation indispensable when it is once introduced. The subject can be whirled from left to right or the reverse, sitting or reclining, the eyes open or shut, and the findings compared with the normal standards which von Stein has carefully ascertained.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A SYSTEM OF PRACTICAL SURGERY. By Drs. E. von Bergmann of Berlin, P von Bruns of Tübingen and J. von Mikulicz of Breslau. Edited by William T. Bull, M.D., *Professor of Surgery in the College of Physicians and Surgeons* (Columbia University), New York. To be Complete in Five Imperial Octavo Volumes, Containing Over 4,000 Pages, 1,600 Engravings and 110 Full-Page Plates in Colors and Monochrome. Sold by Subscription Only. Vol. I—Surgery of the Head. Original Articles.

SOME TOXICOGENIC GERMS FOUND IN DRINKING WATER.

VICTOR C. VAUGHAN, M.D.
Dean of the Medical Department of the University of Michigan
ANN ARBOR, MICH

[Research in the Hygienic Laboratory of the University of Michigan, 1903.]

At the opening of the hygienic laboratory of the Michigan University in October, 1888, I began a new method for the bacteriologic examination of drinking water, which, with various modifications, has been carried out since that time.

THE MICHIGAN METHOD.

The method may be briefly described as follows: The samples are collected in sterilized receptacles and sent to the laboratory without delay. Immediately on receipt, plates are made with 0.05 c.c.,0.1 c.c., 0.5 c.c., and 1 c.c. of the water. For many years only gelatin plates were prepared, and these were grown at room temperature. During the past two years, however, only agar plates are used, two sets being made, one of these grown at room temperature, and the other at 38 C. The reason for this modification will be understood by those engaged in the bacteriologic study of drinking water. The toxicogenic bacteria of water have their optimum growth at 38 C., while many non-toxicogenic bacteria found in water have their optimum at the lower temperature. At the higher temperature the toxicogenic organisms crowd out the non-toxicogenic, while at the lower the reverse is true. The colonies developed on these plates are counted at the expiration of twenty-four, forty-eight and seventy-two hours.

At the same time that the plates are made, beef-tea tubes are inoculated with like amounts of the water, and these tubes are kept in the incubator for twenty-four hours at from 38 to 40 C. This temperature is regarded as a point of importance, and is never allowed to fall below 38 C., for the reason already given that many harmless water germs do not multiply at all, or do so but feebly at 38 C. So far as I know, this fact was first observed in this laboratory, and it has been practically applied ever since the opening of the institution in 1888. If no bacteria develop at this temperature the water is reported as perfectly safe. Certainly it can cause no infectious disease when it contains no bacteria that will grow at the temperature of the human body. It matters not how many thousand it may show per cubic centimeter when grown at room temperature.

When germs are found in any of the tubes after twenty-four hours in the incubator, from 1 to 2 c.c. of the beef-tea cultures is injected intra-abdominally into white rats or guinea-pigs. Generally two animals are thus inoculated from each tube. If none of these animals die from the effects of these injections, the water is regarded as safe. If one or more of the animals die, agar plates are made immediately after death from the heart's blood. The thoracic cavity is opened, the heart exposed *in situ*, its surface seared with a hot iron, and the cavity punctured with a sterile-glass pipette, into which a few drops of the blood is drawn. With the blood thus obtained, the plates are made. The purpose held in view in these animal experiments is to use the animal as a plate for separating the toxicogenic organisms from the non-toxicogenic. These agar plates are developed at 38 C., and the success of the method is largely dependent on the skill and care given to this part of the work. The colonies found on these plates are studied most carefully, and in the routine work five cultures are made from each kind of colony. By this I mean to say that if all the colonies appear to be the same, cultures are made from at least five colonies, while if it is evident that there are two or more kinds of colonies present, five cultures are made from each kind. It is true that this procedure takes considerable time and demands much labor, but it has been found that unless this procedure be carried out, pure cultures are not obtained, and it is subsequently impracticable to differentiate the organisms. It not infrequently happens that when the colonies are apparently the same, we succeed in obtaining two or more germs from them. We have tried for these plates various kinds of culture media, such as litmus-lactose agar, for the purpose of bringing out more differentiation among the colonies. This point is still a subject of investigation, but in the routine work we are employing ordinary agar plates. Sometimes it is found necessary to replate the cultures obtained from the plates originally made from the heart's blood. The cultures obtained from these plates are carried through tests on various media, which will be brought out in detail later. This has been not inappropriately called "The Michigan Method."

RESULTS OF THE EXAMINATIONS.

By this method 709 samples of water have been examined since October, 1888. Of these, *213 have* contained germs that killed animals, while 496 have failed to kill. These figures include only those samples sent by health officers and other physicians, and do not include all of these, because the records of some of the examinations have been lost. It is the purpose of this paper to give in a condensed form some of the most important results obtained by this method, which has now been employed for sixteen years. Before giving the conclusions, it may be well to make some brief statements concerning some of the waters in which toxicogenic germs have been found. In doing this I will group the waters according to the year in which the examinations were made.

1888: From October to December 31, 15 samples were examined by this method, in none of which were toxicogenic germs found.

1889: In this year 41 samples were examined, 13 of which contained toxicogenic organisms. The first water found to contain a toxicogenic germ came from the water supply of Grand Rapids, Mich., at the time of the prevalence of a mild epidemic of typhoid. Two samples were sent, one from the public supply, which was the unfiltered water of Grand River, which receives the sewage of several small cities above Grand Rapids, and the other from a spring near the city. The first contained 720,000, and the second 2,400 germs per c.c. The first killed rabbits, while the second did not. Therefore, the first was condemned on account of both the number and kind of the germs. Our records contain but little information concerning the organism found in this water. It did not correspond to any of the descriptions given in Eisenberg's tables.

The second toxicogenic organism found came from cistern water in Ann Arbor. Five members of a family of seven (all save the father and mother) had typhoid. There were no other cases in the town at the time, and it was not supposed that the members of this family drank the cistern water, but on inquiry it was learned that the young people used it in their ablutions and for cleaning their teeth. Pitchers of the cistern water were kept in their bedrooms, and one remembered that he had occasionally drank it. The cistern was exceedingly dirty, as was found to be the case on examination, and the water contained 60,000 bacteria per c.c. The toxicogenic organism found in this water is that which has been described[1] under the name of *Bacillus aquatilis venenosus brevis.*

Nos. 3, 4, 5 and 6 of this series came from Lake Teal, the water supply of Negaunee, Mich., at the time of the prevalence of typhoid at that place. Five samples were sent for examination, the fifth being from a sand shaft, this did not contain any toxicogenic bacteria.

No. 7 came from a well near Deerfield, Mich., and was sent on account of the prevalence of typhoid in the family using the water. The toxicogenic germ found in this case was a liquefying organism, undoubtedly a member of the proteus group, and I do not believe that it had any causal relation to the typhoid fever.

Nos. 8 to 13 came from shallow wells at Iron Mountain, Mich., and were sent on account of the existence of typhoid in the families using these waters. This also was a liquefying organism, and had no relation to the disease.

1890: In this year 72 samples of water were examined, 14 of which killed animals. Nos. 1 and 2 came from a cistern that supplied drinking water to a fraternity house in Ann Arbor. Investigation showed that the hopper that received the chamber slops leaked into the cistern. The organism found in this water belongs to the venenosus group, which will be described later.

No 3 came from a driven well at Rankin, Ill., was a liquefying organism, and had no relation to the typhoid existing in the family.

No. 4 came from a lake at Soudan, Minn., and was dual for the purpose of ascertaining whether or not the ter or was suitable for drinking purposes. Of the two samples sent, both were from the lake, but at different distances from the shore, and from places of possible contamination. The one nearest the shore contained a toxicogenic germ which seemed to be identical with that obtained from the Negaunee water in 1889.

No. 5 was taken from a well at Soudan, Minn., and was suspected on account of the relative position of the well and privy vault. This organism belonged to the venenosus group. It may be remarked that this water contained only 80 germs per c.c., and was chemically unobjectionable.

No. 6 was from an artesian well at Gladwin, Mich., and was plainly a colon bacillus. The organisms probably came from contamination while collecting the water, as other samples from the same well were not contaminated.

No. 7 was a colon bacillus from a well at Imlay City, Mich. Both of these wells were prospective water supplies, and had not been used.

No. 3 of this series is interesting. It came from the public water supply of Sault Ste. Marie, Mich. This city takes its water supply above the rapids, and ordinarily it is a very pure water. In the fall of 1890, owing to a break in the lock, more than 200 boats were detained for two days above the lock, and in the immediate vicinity of the intake. Some ten days later typhoid appeared, and the deaths were reported to be not less than thirty. All the cases appeared within a few weeks, and this sample was taken with the appearance of the first cases. Samples of the same water collected one month later showed no toxicogenic organisms. The germ found in this water belongs to the venenosus group.

The germ found in No. 9 belonged to the proteus group.

Nos. 10 and 11 came from Wyandotte, Mich., the first from the well of a milkman, whose milk was plainly the cause of the limited outbreak of typhoid. The same germ was found in the water of the well and in the milk, and belonged to the venenosus group. In the public water supply, No. 11, a liquefying organism was found.

Nos. 12 and 13 came from Torch Lake, Mich.; No. 12 from the lake and No. 13 from a well. The men who had typhoid worked at a sawmill on the bank of the lake, and near both lake and well was a large privy that had been used for years and had never been cleaned. A third sample sent at the same time was from another well more than a quarter of a mile distant from the lake, also from the first well. This contained no toxicogenic germs. The men while at work drank from the well near the lake, and when not at work drank from the other well. No one who did not work at the mill developed typhoid. It may not be amiss to state that these facts were not known until after the report was made, the samples having been sent to the laboratory under numbers. The germ found in the well, also that found in the lake water, belonged to the venenosus group.

Nos. 14, 15 and 16 were samples of water from St. Johns, Mich., taken from the public water supply at the time of an outbreak of typhoid. The water was undoubtedly contaminated from nearby privy vaults, and the germs belonged to the venenosus group.

1891: In this year 20 samples were examined, only two of which killed animals. No. 1 of this series came from the public water supply of Duluth, Minn., in January, 1891, at the time of the prevalence of a severe epidemic of typhoid. Five samples were sent under numbers and without intimation of their respective sources. It turned out that four were from hydrants in different parts of the city, and one from a spring. The one in which the toxicogenic germ was found, as the health officer subsequently informed me, was taken from a tap in a doctor's office, the occupant of which had gone home two weeks before with typhoid, and so far as known, the tap had not been used again until the sample sent me was taken. The germ found in this water has been described as *B. venenosus invisiblis*. It may be remarked that an expert bacteriologist in Massachusetts made several examinations of this water during the epidemic and reported it perfectly safe, and well he might. relying as he did on the number of organisms, which in the four samples examined in this laboratory ran from 80 to 800 per c.c. However, no intelligent man will now deny that the epidemic was due to water pollution, whether the germ found in this laboratory was the cause or not.

---

[1] Jour. Med. Sci., August, 1902.

No. 2 came from the public water supply of Adrian, Mich., and was sent on account of the existence of typhoid fever. It was *B. venenosus*.

1892: In this year 37 samples were examined, three of which killed animals. The three waters that furnished toxicogenic germs in this year are not worthy of especial notice. Two were from wells, and were sent on account of the existence of typhoid in the family using the water. In both of these *B. venenosus* was found. The third came from a hydrant at East Lake, Mich., and contained a colon bacillus.

1893: The most interesting sample of this year came from the public water supply of Ironwood, Mich. On June 4, Health Officer Nevin sent a sample because a few cases of typhoid had appeared. I found nothing suspicious about the water, the number of bacteria per c.c. being 4,620, and these seemed to be of only one species, which was identified as *B. fluorescens liquefaciens*. Cultures were injected into white rats without effect. and the water was pronounced safe. On June 10 the superintendent of the water works sent a sample. The number of bacteria was increased. being now 7.680 per c.c., but this was not alarming. The *B. fluorescens* still predominated, but in addition there was *B. venenosus*. This water was condemned, but the superintendent of the water works failed to notify the citizens that the water was unsafe, and nearly 700 cases of typhoid fever developed within three weeks. Samples of this water were repeatedly examined during July and August of this year, and *B. venenosus* continued to be present until August 8. The next examination was made August 25, when *B. fluorescens* and *Diplococcus aquatilis* were the only organisms detectable.

1894: In this year 50 samples were examined, 20 of which killed animals. On May 4, 1894, it was found that the Ann Arbor water supply contained *B. venenosus*. The water at that time came from several springs, and the contamination was traced to one of these; that is, this organism was sought in the water of each spring, and found in one only. This spring was detached from the pumps, and the reservoir in use at that time emptied, every hydrant in the city opened. and reservoir and pipes washed out, the bottom and walls of the reservoir whitewashed, and then the reservoir was filled with water from the uncontaminated springs. During the month of May there were five cases of typhoid reported in the city. The next examination of this water of which we have a record was made May 15, when it was found to be free from harmful organisms. In January, 1894, *B. venenosus* was found in the water supply of Grand Forks, N. Dak., where typhoid then prevailed. January 29 two samples, one taken from the mouth of the intake and the other from the pump, were sent for examination. The toxicogenic germ was found only in the water from the intake, and the decision on this water was as follows: "*B. venenosus* I regard as a variety of the typhoid germ. The use of this water should be discontinued." It may be remarked that, so far as the number of bacteria is concerned, both of these samples made a good showing, No. 1 having 1,000 and No 2 800 per c.c. after forty-eight hours. It may be worthy of note that the germs found in the sample from the intake were *B. venenosus, B. fluorescens* and *B. figurans*. Possibly it is also worthy of note that on February 5 I examined ice taken from the Red River above Grand Forks. This ice contained no toxicogenic bacteria, but each c.c. of the water obtained by melting the ice contained 1,280,000 bacteria, and the following recommendation was made: "There is no proof that this ice can cause any disease. However, the large number of non-toxicogenic germs renders it undesirable for drinking, and this ice should not be placed in milk or other drinks next summer." The Grand Forks water continued bad for many months, samples having been examined from time to time. On July 14, 1894, I examined two samples each from Red Lake River and Red River above the confluence of these streams. The former contained *B. venenosus* and *B. liquefaciens albus*, and the second contained *Proteus vulgaris, B. liquefaciens albus,* and *B. fluorescens liquefaciens*. The two samples of Red Lake River water contained, respectively. 58,000 and 38,000 bacteria, and those from Red River 120,000 and 160,000 per c.c.

1895: In this year 48 samples were examined, 13 of which contained toxicogenic germs. In the summer of this year a number of cases of typhoid developed simultaneously among the guests at the Mexican Gulf Hotel at Pass Christian, Miss. The samples of water came from an artesian well at the hotel, and were sent by Dr. LeRoux. The first sample was examined July 27, 1894. The plates, which were gelatin, and kept in the cooler at 18 to 20, showed no growth at the expiration of twenty-four hours. At forty-eight hours there had developed 2,000; at seventy-two hours, 3 000 per c.c. The germs present were *B. albus* and *B. coli communis*. The latter was not typical. and intraperitoneal, subcutaneous and intravenous injections were made in rats, guinea-pigs and rabbits. The amount used varied from 0.5 to 2 c.c. of a beef tea culture twenty-four hours old. Death occurred in all within from twelve hours to three days. The peritoneum—whatever the method of inoculation—contained a plastic exudate; the mucous membrane of the small intestine was inflamed, and the spleen in the more protracted cases enlarged. The organism was obtained from the heart's blood, spleen, liver and kidney. The record shows that it was "an oval motile bacillus, with length from two to two and one-half times the breadth." Unfortunately the description stops here. The recommendation was as follows:

> If the jug in which the water was sent was thoroughly sterilized and the germ found really exists in the water as it is taken from the well, the use of the water should be discontinued. As stated above, this is not a typhoid germ, but it may induce symptoms resembling those of typhoid fever.

On August 16 three samples, one from the Mexican Gulf Hotel well and one each from West End and

East End artesian wells, were received. At the expiration of twenty-four hours no colonies were seen on any of the plates. After forty-eight hours the hotel water showed 200, the West End 500 and the East End 2,000 per c.c. The only organism detected in any of these waters was *B. albus*. The recommendation was as follows:

> These waters in their present condition can not cause disease. Let it be understood that this statement is based exclusively on the results obtained by the bacteriologic examination of the samples sent. The water from the Mexican Gulf Hotel first sent did contain a toxicogenic germ. Whether this germ was an actual constituent of the water, or due to imperfect sterilization of the jug, I can not tell. If there was a poisonous germ in the water it had evidently disappeared before the small bottles were sent. If this water has been contaminated once, it may become so again, unless the conditions are changed. This should lead to the most careful examination.

These waters were again examined September 10, and *B. albus* only was found.

In September, 1895, a small outbreak of typhoid fever occurred at Mt. Iron, Minn., and led Dr. Brown to send two samples of the village supply, in both of which a colon-like bacillus was found. In the public water supply of Pontiac, Mich., there was found the only toxicogenic coccus ever found in drinking water in this laboratory, in July, 1895. After death from peritoneal injection, the liver was studded with small pustules. "The organism which caused the death of these animals is a pus germ, and probably came from the container."

In March, 1895, *B. venenosus invisiblis* was found in two samples of well water from Port Huron, Mich., where typhoid fever was present in families using these waters. The water of a third well, used by a family in which typhoid existed, showed no toxicogenic germ. These three wells were in close proximity, and it may be of interest to give the number and kind of bacteria in the waters of each. No. 1 contained 2,000 bacteria per c.c. counted at the expiration of twenty-four hours, and these were *B. albus* and *B. fluorescens liquefaciens*. No. 2 showed 4,000 colonies, and these were *B. albus putridus*, *B. fluorescens liquefaciens* and *B. venenosus invisiblis*. No. 3 developed 500 colonies, and the germs corresponded in kind with those in No. 2.

1896: In this year 51 samples were examined, 15 of which contained toxicogenic germs. In February of this year the Duluth reservoir was emptied and cleaned on account of the appearance of typhoid. Some of the muddy water from the bottom of the reservoir and some of the scrapings from the outside of a Chamberland bougie, through which this water had been filtered for forty-eight hours, were examined. The number of colonies, even when one drop of the water was used, were too great to be counted, and no attempt was made to isolate the different non-toxicogenic bacteria. Cultures from the heart's blood of animals killed with these waters revealed the presence of a bacterium, of which the following is recorded:

> This germ is not identical with the typical Eberth bacillus, but it belongs to the same group. Its chief characteristics are as follows: (1), it is motile; (2), it does not liquefy gelatin; (3), it does not coagulate milk; (4), it does not give the indol test; (5), it forms a yellowish-white growth on potato; (6), in pure cultures it is toxicogenic to animals. It is the belief of the undersigned that water containing this germ is not a safe drinking water.

In September, 1896, *B. pyocyaneus* was found in the public water supply of Milwaukee, Wis. This was the first time that this organism had been found in samples sent by health officers. It had been frequently obtained from the waters of unused wells. I have never considered the finding of this germ a cause for condemnation of the water. Typical colon bacilli were found in three samples of Milwaukee water, but soon disappeared. They were present in all three samples examined September 17, but had wholly disappeared by September 25. Our records show that cities taking their water supplies from the Great Lakes when the intake is close to the shore, and especially when the intake is from a land-locked bay, frequently drink colon bacilli. This is true of Menominee, Marquette, Traverse City and Petoskey.

1897: In this year 32 samples were examined, only one of which contained a toxicogenic germ. This water was from Marquette, Mich., and the organism was a typical colon bacillus. The water of this city was examined monthly for some years, and on account of the occasional finding of the colon bacillus, the intake was moved out into the lake, and since that time the colon bacillus has been found in the water only once.

1898: In this year 56 samples were examined, 13 of which contained toxicogenic germs. While many of these have more or less interesting features space will prevent me from referring to more than a few. In March of this year a serious epidemic of typhoid appeared at St. Clair, Mich., and the public water was clearly responsible for the disease. This water was repeatedly examined, and a typical colon bacillus was obtained each time. Every known process for the separation of colon and typhoid bacilli was tried (except that of making a number of cultures from every plate, even when the colonies have the same appearance, and which is now used in this laboratory), but the results were always negative. The germ obtained was a short, slightly motile bacillus, with rounded ends. It coagulated milk within twenty-four hours, gave the indol test, reddened litmus and evolved gas from glucose and lactose cultures. The public water supply was taken from the St. Clair River, and it was supposed to be taken at a distance of some 200 feet from the shore, but investigation showed that the intake pipe had been broken by the ice, and the water was, in fact, taken not more than 20 feet from the shore. Within a quarter of a mile above this point several privies emptied into the river. The intake pipe was repaired and extended a distance of about half a mile, and beyond a long sand bar which ran parallel with the shore, and after this was done the epidemic ceased. It was first asserted by the people of St. Clair that their water supply was contaminated by the sewage of Port Huron, some ten miles up the river; and the water of the St. Clair River, at the mouth of Black River, carrying the sewage of Port Huron, was examined. In this we found "a highly motile bacillus which coagulated milk, reddened litmus, evolved gas and gave the indol reaction. This water is contaminated with fecal matter, and the colon bacillus found in it is highly virulent." However, there is no reason for supposing that the epidemic of St. Clair was due to infection at Port Huron for the following reasons: (1) The main current of the river was beyond the sand bar at St. Clair; (2) the broken pipe at St. Clair and the privy vaults were sufficient to account for the contamination of the St. Clair water, without going to Port Huron to look for the source of the trouble; (3) the epidemic promptly ceased as soon as the local conditions were improved, TABLE SHOWING CERTAIN CULTURAL PROPERTIES OF SOME BACTERIA FOUND IN WATER.

notwithstanding the fact that Port Huron continued to empty its sewage into the river. It might be added that analyses of the Detroit water in March, 1898, failed to show any toxicogenic organism, notwithstanding the sewage of Port Huron and the typhoid at St. Clair.

1899: In this year 35 samples were examined, only two of which contained toxicogenic germs. A non-liquefying motile bacillus which did not coagulate milk, redden litmus or give the indol test, was found in the water of a well at Charlevoix, Mich. Typhoid existed at that time in the family using this water.

1900: The colon germ was repeatedly found in the water supplying the Fletcher Paper Company at Alpena, Mich. There was no typhoid fever among the employes. *B. venenosus* was found in well water sent from Yale, Mich., on account of the existence of typhoid in the family using the well. The same organism was found in the water of Lake Sally, supplying Ishpeming, Mich., at a time when typhoid fever prevailed in that city. Three samples were sent, and the same germ was found in each.

It is an interesting fact that *B. venenosus* was found in the water of Island Lake in 1898, and two years later the same organism was found in this water. This is a small lake, on the shore of which the five Michigan regiments recruited in 1898 had their state encampment, and where the Thirty-fifth Michigan developed an epidemic of typhoid of serious proportions. This lake is quite remote from any village, receives no waste except from a few farm houses, and is not used as a water supply. *B. venenosus* was found in the waters of three wells at a time when typhoid existed in the families using these waters.

1901: In this year 57 samples were examined, 23 of which contained toxicogenic germs. During the fall of 1901 and the winter of 1901-02, the people of Ann Arbor drank daily a water that contained a typical colon bacillus, and the same is true of at least two other small cities in Michigan, and there was no typhoid at any of these places. During the summer of 1901 several examinations were made of both the filtered and unfiltered water supplied at Homestead, Pa. The unfiltered water contained a typical colon bacillus, while the filtered samples contained no toxicogenic germs. However, we have examined many samples of filtered water in which we have found colon bacilli.

1902: In this year 31 samples were examined, 14 of which contained toxicogenic germs. The most interesting case investigated during this year came from Elk Rapids, Mich. This village takes its water supply from Elk Lake, around the shores of which there are numerous possibilities of contamination, and some of these are not distant from the water intake. In February, a limited outbreak of typhoid led to the water being sent for examination. All of the samples contained a toxicogenic germ that was reported as belonging to the colon group, but more extended study makes this classification doubtful. These waters undoubtedly did contain the colon bacillus, but by the extra care in plating already referred to, we obtained from each of these in addition to a typical colon germ, another. This second organism was highly motile, did not coagulate milk, did not redden litmus, did not give the indol test, but did ferment glucose, lactose and saccharose.

1903: During this year 87 samples have been examined, 54 of which contained toxicogenic germs. A few of these are described sufficiently in the accompanying table. The figures accompanying the signs in this table are employed to indicate the relative action of the germ on a scale of 10. For instance, in the column "Indol," the figure 5 indicates that the indol reaction was one-half as marked as it is in cultures, giving the very best indol reaction.

Nos. 1 and 2 in this table are typhoid cultures, and are given here simply for the purpose of comparison. No. 3 is the laboratory culture of the colon bacillus, and is given for the same reason that Nos. 1 and 2 are inserted.

No. 4 is a non-toxicogenic organism, and is inserted here for the purpose of illustrating how easy it might be for one to suppose that he has detected and isolated a typhoid bacillus in water, when the pathogenicity of the organism is not tested. This germ was found in water obtained by melting a piece of ice, and it will be seen that in practically every particular as given in the table, it conforms to the typhoid germ, but even 5 c.c. of the beef tea culture of this organism injected into the abdominal cavity of a guinea-pig weighing from 200 to 300 grams is absolutely without effect. The organism is strictly a saprophyte, and notwithstanding its close cultural similarity with typhoid fever, it is a wholly different organism. I described this germ in 1891 under the name of *B. aquatilis invisiblis.*

No. 5a is a fairly typical proteus organism, as found in drinking water. It liquefies gelatin more rapidly than most samples belonging to this group, and its production of indol is less. Waters containing the proteus germ only are not condemned. However, repeated plating is necessary to be sure that some non-liquefying organism is not mixed with the proteus.

The germs described under Nos. 6 and 7 came from two samples of water sent to the laboratory by Lieutenant Thomason, U. S. A., from the Army post at Whipple Barracks, Ariz. Dr. Thomason wrote as follows:

> The water supply to this post is identical with that of the city of Prescott. It is derived from the valley of the Del Rio, twenty-two miles north. Its source is from a large spring, one of a series of springs, apparently from the same underground source, that bubble up at frequent intervals along the valley for a distance of two and a half miles, and then entirely disappear. These bubbling springs must originate from some subterranean stream. So far as can be ascertained, there is ordinarily no opportunity for contamination. Unfortunately the pipe line leading to this source of supply is undergoing repair, which will require several weeks. In the meantime the city and post are at present being supplied from a well dug in a river bed (the river beds in this country are dry several months in the year), which collects the waste of the greater portion of the town. This supply has, in my opinion, every opportunity for infection. Animal inoculations with germs obtained from this water have in my hands proved toxic, guinea pigs having died within 24 hours. We have not experimented with the Del Rio supply from want of animals. . . . The drinking water used in the garrison has been boiled since I discovered the character of its present supply. Typhoid fever has been endemic in the city of Prescott for years. Many persons having typhoid fever claim that they used no other water than that from the Del Rio supply.

The Del Rio water furnished us with the three germs described under 6, and the well water with the two germs described under 7. Guinea-pigs inoculated with water No. 6 died within fourteen hours. By plating and replating from the heart's blood of these animals, we obtained the organisms described under 6a, 6d and 6e. We have studied these germs very carefully, and it is possible that 6d and 6e are the same organism. They certainly belong to the same group, and we have classified them as proteus germs. It will be observed, however, that while 6d is motile, 6e is non-motile. 6d produces indol, while 6e does not; 6d coagulates milk more promptly than 6e. However, we do not lay a great deal of stress on this point, nor on the slightest differences seen in the potato cultures, except that 6d was colorless on potato, while 6e was plainly yellowish pink. So far as gas production is concerned, the two germs might be the same. Whatever the relation between 6d and 6e, both of these certainly differ from 6a. The latter does not liquefy, does not produce indol, does not coagulate milk, even after ninety-six hours, and does evolve a much larger amount of gas than either 6d or 6e; 6a, as will be seen from the table, we have classified as doubtful. This water would be condemned.

The differences between 7a and 7b are plainly seen. 7a is a non-liquefying, while 7b is a liquefying organism. 7a produces no indol, while 7b produces this substance in abundance. 7a neither coagulates nor produces acid in milk; 7b does both. 7a is a typical germ of the class, which in this laboratory we have designated under the head of venenosus. Its close resemblance to the typhoid bacillus is easily seen by a study of the table.

8a came from a spring which breaks from a hillside, the top of which is covered with houses, and there are many chances of pollution. This organism certainly belongs to the proteus group, and the water is not condemned.

14a and 14b were obtained from the heart's blood of animals inoculated from the public water supply of Petoskey, Mich. It will be seen that one of these does not liquefy gelatin, while the other does, and one produces no indol, while the other produces this substance. One coagulates milk more promptly than the other. So far as growths on potato and the evolution of gas are concerned, these organisms closely resemble each other. 14a is classed as doubtful, and 14b as proteus. The water is condemned on account of the presence of 14a.

20a, 20b and 20e were obtained from the heart's blood of animals inoculated with water from Battle Creek, Mich. 20e is quite typical of the group venenosus. 20b certainly belongs to the colon group, while 20a we have classed as doubtful. This water is condemned.

21a was from a test well sunk in searching for good water. The water was not condemned.

22a is what we have called *Bacillus venenosus brevis.* Under the microscope this short bacillus may easily be mistaken for a coccus, especially in stained specimens, but when examined in a hanging drop, it will be seen that it is a short motile bacillus. 22e is classed as doubtful.

9a came from a well near Ann Arbor, and was sent for examination because one man in the family using this water developed typhoid fever. It must be stated, however, that this man was several times away from home, and at least once, about two weeks before the development of the disease, spent twenty-four hours in a city where typhoid fever was prevalent.

10a and 10d are interesting. They were obtained from the heart's blood of the same animal. The water came from a well at a farmhouse in which there were two cases of typhoid fever, one of extreme severity and the other light in character. The only marked difference between 10a and 10d is that 10a produced acid in milk, while 10d did not. Neither coagulated milk.

11, 12 and 13 came from different samples of water. All these waters were sent from Petoskey. 11a came from a test well, while 12a and 13a came from the city supply. 11a was not condemned; 12a and 13a were condemned.

CONCLUSIONS.

1. Of 709 samples of drinking water sent by health officers and ot[illegible]e hygienic laboratory of the [illegible] between Oct. 1, 1888, and Dec. 31, 1903, 213, or 30 per cent., contained toxicogenic germs.

2. Ten samples, or 1.4 per cent., contained no bacteria capable of growth at 38 C. Of these 10 samples, 4 were from deep springs, and 6 from the Great Lakes —4 from Lake Superior and 2 from Lake Huron.

3. Waters that contain no germs capable of growth at 38 C. or higher can not cause disease.

4. Waters that contain no toxicogenic germs are not condemned.

5. Waters that contain as their only toxicogenic organism a typical colon bacillus are not condemned. By a typical colon bacillus we mean one which is nonmotile, produces indol abundantly, produces acid in milk, coagulates milk within twenty-four hours, and evolves more or less gas from glucose and lactose cultures.

6. Waters which contain as their only toxicogenic organism a typical proteus bacillus are not condemned. It must be remembered that other germs can not be excluded until after repeated plating of the cultures made from the heart's blood fails to show their presence.

7. Waters that contain any member of the venenosus group or any such germ as we have marked doubtful in the table given are condemned.

8. I have never found in drinking water a germ that responded to the Widal test.

9. Sixteen years of experience with this method of water analysis convinces me that the results given by it are in the majority of instances trustworthy.

The development of this method of water analysis and its application have been largely due to the skillful and conscientious work of the many assistants who, since 1888, have worked with me on this subject. I can at present do nothing more than mention their names. During the first three years I had the assistance of the late Dr. F. W. Brewer, who subsequently became a professor in the Agricultural College of Utah. Much credit is also due to Drs. Ives, McClintock, McClymonds and Cooley; and the method owes much to my more recent assistants, Drs. Carhart, Cooper and Williams.

A CASE OF ATROPHY OF HAND MUSCLES

WITH LOCALIZED SENSORY DISTURBANCES; POSSIBLE EARLY SYRINGOMYELIA.*

D. I. WOLFSTEIN, M.D.
CINCINNATI.

The following case is reported because it possesses very interesting features:

History.—Miss L., aged 27, consulted me first, Feb. 27, 1903, sent by her family physician because of a localized wasting of the thumb. There is no neuropathic family taint, nor has any myopathic disease ever been present in the family so far as known. Two other sisters were examined carefully with negative results. The girl is unusually tall and very slender. While tallness is a family characteristic, she is the tallest of all. Tuberculosis has not existed in the family, and patient is also free therefrom.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Nervous and Mental Diseases, and approved for publication by the Executive Committee: Drs. Richard Dewey, H. A. Tomlinson and F. W. Langdon.

Pain in the right arm has been noticed since her twelfth year. The arm has also seemed weaker at times than the other, but she has performed all the arduous duties of laundry and house work for many years. There is no history of the supervention of the pain and weakness after any illness, acute or otherwise, which might be regarded as an etiologic factor. Trauma is not in evidence. The pain was never severe in character, but always more noticeable after any special muscular effort, or when heavy clothing was worn. Neither quivering nor twitching has ever been noted. During the last five years and up to the date of the institution of electric treatment by me cramps would appear in the fingers of the right hand. These cramps would cause a stiffening of the fingers, producing extension of the hand on the wrist and flexion of the distal phalanges. Occasionally only two fingers would stiffen in this way, sometimes the little and ring finger, at others the thumb and neighboring two. The cramps would come on several times daily for a few weeks, followed by free intervals of varying duration. There was never any tendency of the cramps to further extension to the arm, and, as said, since the beginning of electric treatment they have been absent.

About three to five weeks prior to February 27, 1903, she noticed for the first time a sinking in of the thumb. She was positive that the wasting must have occurred at about the time stated, certainly not at a period much earlier. It is, however, my impression that the atrophy did not come on so suddenly as she states, though her opinion on this point is quite firmly maintained.

Subjective sensory disturbances were never observed. At no time did she complain of any "numbness" or "tingling" or "coldness," and when questioned by me she did not recall any such symptom.

To sum up she came to me solely because of the atrophied muscle, for had she not discovered this the weakness and pain would have appeared of not much import.

Examination.—Patient is 6 feet 2 inches high, very slender, weight 146 pounds. The right arm shows no change, either in the muscles above or below the elbow, but along the outer border of the thumb there is a decided wasting. This is limited to that part of the thenar eminence occupied by the opponens, and the outer part of the abductor pollicis. The interossei and lumbricals are not involved, consequently there is neither deepening of the spatia interossei or the palm.

Movements of Thumb: Abduction and apposition are both performed with less power than on the left. The grip of the right hand is slightly less than the left. Flexion, extension and all other movements of the arm, wrist and hand are properly performed, but on the whole the strength is slightly diminished.

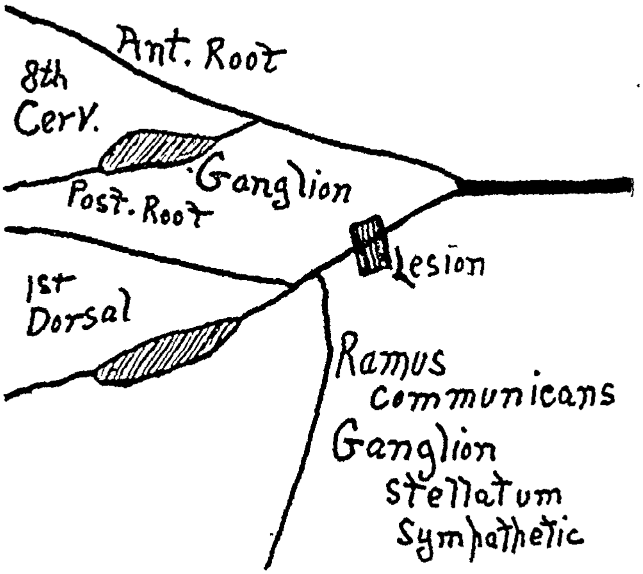
Electric Examination: Reactions are prompt with both currents to equal current strength in all arm and hand muscles, except in the case of the right musculus opponens and abductor.

Pollicis: In these two there is a marked quantitative change to both currents, and the response to both faradic and galvanic is slower than the normal type.

Sensation: No objective disturbance of any kind is present anywhere in the body, except along the ulnar border of the right arm. At the first examination I found a narrow area of sensory change beginning at the internal condyle, and extending in a straight path not over one-half inch wide at any point to the pisiform bone. In the upper third of this narrow area there was thermo-anesthesia; cold was often called warm, very hot was called warm, and occasionally even cold. Tested with the ether spray and cautery the results were similar. In the upper half of this dysesthetic area, or band, there was a considerable degree of analgesia. Throughout the entire area there was a hypesthesia, and in several spots the size of a dime complete anesthesia. With the probability of incipient syringomyelia in view, careful tests for dysesthesia elsewhere were made, and as was the case with the motor disturbance, none was found other than as herein indicated. After two or three weeks electrization, the thermo-anesthesia and analgesia became much less apparent, and indeed I may say that by repeated tests on different days I failed to elicit the marked departure from the normal type, so well seen when first examined. On one or two occasions, however, they would apparently recur, but in a more uncertain and negative manner than at first. On the other hand, the anesthesia, or at least the hypesthesia, was always manifest along the whole narrow band, but never above the elbow. There were no oculopupillar symptoms present. The reflexes were nowhere increased.

The salient features of this case then are: (*a*) Isolated atrophy of two thumb muscles, subacute in its beginning, showing, so far as the limited time of observation will permit any inference, no progressive tendency; (*b*) definitely localized dysesthesia.

The sensory disturbance present differs from the true dissociated sensory type of syringomyelia. In the latter, preservation of tactile sensibility is the rule, in this case hypesthesia prevails. It is true that even in syringomyelia there may be disturbance in the tactile element of sensibility. Roth found it in the proportion of 1 to 18, and considered it to indicate an invasion of the posterior tracts by the gliosis or cavity formation. When it occurs, therefore, we should expect it to be, and it really is, a late and not an early symptom, being due to the extension of the syringomyelic process. I am unable to find the presence of marked anesthesia as an early symptom of syringomyelia anywhere recorded. I also find but little reference to early syringomyelia, and find no case of it with such slight unilateral muscle atrophy, and such strictly localized sensory change as shown in this case. It appears to me rather difficult to picture a gliosis or cavity formation even in the incipient stage—so situated as to occasion the lesion peculiar to my case. Syringomyelia may, therefore, be excluded.



Suggested diagram of location of lesion. (After Buzzard.)

This case comes under the class of uniradicular palsies, so well described by Buzzard in *Brain*, 1902, where the meager literature of the subject is also cited. Six cases are here detailed, all of which involved one or more of the roots of the brachial plexus; some of the fifth and sixth cervical, others the first dorsal, and in one case the lesion appears to have attacked the fifth cervical and first dorsal, i. e., the upper and lower roots of the plexus. There was thus produced a partial Erb, and a partial Klumpke. The root involved in my case is the first dorsal, and evidently in such a way as to exclude the sympathetic fibers for the pupil.

It is difficult to understand why the atrophy should be confined to the two superficial thumb or thenar muscles, and why the little finger muscles at least should not also have been involved. The interossei, lumbricals and the long flexors of the hand are not exclusively supplied by the first dorsal, but receive their innervation in part from the eighth cervical. Kocher's table gives the eighth cervical complete control over the long finger flexor muscles, and the first dorsal, according to the views of the same author, controls all the small hand muscles. If we adopt this scheme of Kocher's, with which that of Bruns closely corresponds, but from which that of Edinger and Starr is at variance, we shall be able to understand why a lesion of the first dorsal root need not involve the long flexors of the fingers and hand.

It will be less easy to explain why the other small hand muscles should escape and the atrophy involve only the two superficial thumb muscles. It must be remembered, however, that it was stated that the whole right hand was weaker than the left, and although electric changes or atrophy could not be demonstrated in the hypothenar, interossei and lumbrical muscles, a certain degree of implication may still be present or may yet set in. The site of the lesion must be above the point where the ramus communicans of the sympathetic to the ganglion stellatum is given off, as no oculopupillar symptoms were present.

The absence of any increase of reflexes, so frequent in syringomyelia, may also serve to indicate that the cord itself is intact. The presence of sensory disturbance and the course of the affection warrant one, I think, in excluding atrophy of the Aran Duchenne type.

Now with reference to the sensory disturbance, the point is well made by Buzzard that there was no knowledge of any change in sensation on the part of the patients themselves, whereas in peripheral neuritis subjective sensory phenomena are the rule. Buzzard thinks that this absence of subjective sensation of numbness or tingling may prove a differential diagnostic point between root and peripheral neuritis. The character of the dysesthesia, furthermore, is allied to that experimentally produced by a severance of a single posterior root, and as has already been mentioned, different from that form seen in syringomyelia.

I quote from Buzzard the original words of Sherrington:

> 1. The disturbance of skin sensation produced in macacus by severance of spinal roots is to some extent a dissociative one.
>
> 2. In macacus the destruction of a single sensory spinal root, at least in the case of certain spinal nerves, entails in a limited skin area, much smaller than the total skinfield of the root, an abolition of heat sensitivity without abolition, but with some concomitant impairment of actual sensitivity.
>
> 3. In the skin of macacus the pain field and the heat field of a single sensory spinal root, at least in the case of certain spinal nerves, are each less extensive than is the "touch field" of the same root.

The changes in my case correspond closely to this description of Sherrington's, i. e., there was a small algesic and temperature field and a larger touch-field. The site of the lesion is in my case near the point of junction of the eighth cervical and first dorsal to form the outer cord of the brachial plexus, but attacking a single nerve only, viz., the first dorsal.

The lesion must be beyond the posterior root ganglion, as evidenced by the absence of herpes. The limitation of the atrophy to the two superficial thenar muscles, and, furthermore, the absence of any sensory changes in the zone of the first dorsal root above the elbow would seem to plead for a very small vascular lesion of some kind. The prodromal period in my case, or rather the pre-atrophic stage in which the only symptoms were pain and weakness, was rather longer than in any of the cases mentioned in Buzzard's paper, but it is my impression that the atrophy was present for a much longer time than the patient stated.

As to the character of the lesion I have nothing to offer that would not be entirely speculative. The only improvement has been the absence of cramps (which I never saw) and the decrease of the pain. The sensory changes became less marked and more variable, but the atrophy remains unaltered.

DISCUSSION.

Dr. H. T. Patrick, Chicago—I would suggest that this case was possibly an example of the local atrophy which affects most frequently the hand muscles of persons who are engaged in certain occupations. It is usually accompanied by pain. The cases nearly always recover. They are generally seen in just the kind of people Dr. Wolfstein has described—tall, slender, poorly nourished individuals. In my experience, it occurs most often in seamstresses and in girls who work at bookbinding, as well as in other occupations where there is a particular strain on a certain group of muscles. It is, perhaps, allied to some forms of writer's cramp or palsy. Very little can be found on the subject in the text-books. I do not offer this as a positive diagnosis in Dr. Wolfstein's case, but merely throw out the suggestion, as he did not mention this possibility in speaking of the diagnosis.

Dr. Wharton Sinkler, Philadelphia—The trouble was apparently of peripheral origin. I recently saw a stunted, undeveloped boy of fourteen, who worked hard at manual labor and was a heavy cigarette smoker. He got into a fight, and received a severe blow on the back of the hand. Quite a swelling developed, and subsequently there was a loss of power in the extensor muscles of the hand, with marked atrophy of the thenar and hypothenar eminences. In that case the trouble was undoubtedly of peripheral origin.

Dr. Albert E. Sterne, Indianapolis—I also was impressed with the idea that the trouble in Dr. Wolfstein's case was in all likelihood due to the occupation of the woman. Dr. Patrick's statement that these patients usually recovered is not in accord with my experience. Still, recovery often occurs. Three years ago I noticed that the ball of the first finger of my right hand, as well as the thenar eminence, began to shrink. This was accompanied by muscular twitchings, which became so violent that I could scarcely hold a knife. I worried a good deal about it, as there was also some pain, and in addition to this I had a localized pain on the left side of the head. If I had seen such a case in my office, I would unquestionably have kept in view the possibility of a gross lesion in the brain. At the Atlantic City meeting I took occasion to speak to Dr. Patrick about it, and he advised me to spend a month at the seashore. I took his advice, and the twitching and pain disappeared. It has since recurred in different regions, but has not been so persistent. In this connection I would recall that in my own paper I referred to this local neurasthenia as being vascular, due to overcirculation and overexcitation, and I am inclined to think that the case reported by Dr. Wolfstein might belong to the same category.

Dr. F. W. Langdon, Cincinnati—I saw this case with Dr. Wolfstein. At first glance, I was inclined to believe that it was one of early syringomyelia, but the later symptoms made me more doubtful, and finally I practically excluded that idea. Dr. Wolfstein's explanation that the symptoms were due to a root lesion I regard as very probable, more so than the explanations offered by those who have taken part in the discussion. An occupation atrophy could hardly be conceived of that would affect merely one or two muscles. The distribution of the atrophy and the sensory symptoms would also exclude traumatism, to which reference was made by Dr. Sinkler. I see no reason why there should be these objective sensory disturbances as the result of overworking a few muscles. I think the probabilities are in favor of the case being one of radicular palsy, and this view is strengthened by the cases of Buzzard referred to by the author. My experience with cases of muscular twitching has not been always as happy as that of Dr. Sterne in his own case. Some years ago I was consulted by a physician of 40, who had been overworked and somewhat worried. He complained of a loss of dexterity of the right hand, with twitching and numbness. After examining him, I advised him to spend a season at the seashore. This he did, and on his return his health was apparently restored. Shortly after he was found dead in his bathroom, death having been caused presumably by cerebral apoplexy. This shows that we can not always eliminate the presence of cerebral trouble, even if the local symptoms improve.

Dr. D. I. Wolfstein—The simple explanation of these symptoms naturally appeals to us, and we thought first of the existence of an occupation neurosis, but on account of the train of symptoms that developed and the peculiar sensory disturbances of the dissociated type, I believe that explanation of the case can be positively excluded. The woman's occupation was that of a general houseworker, and she did not spend much of her time at laundry work.

ACCIDENTAL PERFORATIONS OF THE UTERUS.*

D. S. FAIRCHILD, M.D.
Professor of Surgery, Drake University College of Medicine; Surgeon to Mercy Hospital.
DES MOINES, IOWA.

Accidental perforations of the walls of the uterus by instruments in gynecologic practice and in efforts to produce abortion are probably more frequent than the reports of cases would appear to show. The circumstances under which these accidents occur are generally such as would lead them to be passed over and the results which sometimes follow are often no doubt assigned to other causes.

Dr. Brothers of New York has been able to collect sixty-six recorded cases of accidental perforations of the uterus, of which seventeen died and forty-nine recovered.

The use of the sound and the curette in gynecologic practice is probably the most frequent cause of this accident in legitimate practice. The facility with which the sound can be used in exploring the interior of the uterus and in repositing a retrodisplaced organ is no doubt responsible for some of these accidents.

There are no means by which we are able to measure the resistance which the uterine walls may offer to the passage of an instrument, or to determine the ease with which the walls may be penetrated. It is well recognized that when the tissues of the uterus are much softened by inflammation or by degenerative changes in connection with disease that a curette or sound will pass through into the abdomen with so much ease that the fact may not be at once recognized, and it may be sometimes assumed that the depth of the uterine cavity is much greater than the facts will warrant, or it may be thought that the sound has passed into a fallopian tube. It is possible that the instrument has been diverted into the tube, but the probabilities are very much greater that the abdominal cavity has been entered.

When the walls of the uterus are apparently healthy they may be penetrated with greater facility than is generally supposed. This fact will be illustrated by a case related in this paper. While I have never had the accident happen in my own practice, I have always been apprehensive of it, and have been governed by a degree of care which has equaled that exercised in any work I do. There can be no doubt that examinations of the uterus by the sound are altogether more frequent than they should be. I am so certain that information as to the condition of the uterus can be better obtained by other means that I rarely use the instrument.

The curette is no doubt a very useful instrument in a certain class of chronic intra-uterine affections, and often indispensable, but at the same time a very dangerous one. I am quite sure that it is often used in an indiscriminate manner, and as a routine treatment in a great variety of uterine difficulties that could be better treated by other means with a greater prospect of permanent results.

The perforation of the uterine walls by the curette would not be so serious if it were not for the associated treatment which is so often regarded as essential when the curette is indicated. I refer to irrigations. If the uterus is perforated and irrigation is employed a considerable amount of infection material may be washed into the abdominal cavity and the chances of setting up a fatal peritonitis are great. The infection from the curette is serious enough, but when in addition to this the washings from the uterus are carried into the peritoneal cavity, the risk is greatly increased. It should be remembered that when the curette enters to an unexpected depth there is a great probability that the instrument has passed through the walls and the irrigation should be refrained from unless it can be absolutely demonstrated that no perforation has taken place.

Our attention is called from time to time to cases where simple curettage has been performed, followed by a fatal result. It may fairly be presumed that in some of these cases the uterus has been perforated and the peritoneal cavity infected without the knowledge of the operator. Indeed, we have known of cases where not only were the uterine walls perforated, but a considerable quantity of gauze was packed into the abdominal cavity through the opening in the uterus, which was only discovered on postmortem examination.

In April of this year a case came under observation which illustrates the ease with which a perforation of an apparently healthy uterine wall can be accomplished, and what needs to be done in cases of this kind.

Case 1.—*A woman about thirty years of age had acquired considerable skill and dexterity in producing abortion by introducing instruments into the uterus.* Suspecting herself to be pregnant or of the possibility of being pregnant, she, about 4 o'clock in the afternoon, straightened out a hairpin, then bent the end over on the main stem to make a close loop so as to avoid the sharp end, which she thought might injure the uterus. She then lay down and introduced the loop end of the hairpin into the uterus, allowing the opposite end to project from the os so that she might remove it at pleasure. After resting in bed two hours she attempted to seize the pin with thumb and finger to remove it, but it slipped from her fingers. She attempted to seize it again, and again it slipped from her and *disappeared within the uterus.* She at once summoned her doctor, who attempted to secure it with a pair of uterine dressing forceps, but failed. The woman was now in great fear of the results, and her physician finally persuaded her to go to the hospital, where I saw her the next morning. She was so certain that the hairpin was in the uterus or the abdominal cavity that she was willing to submit herself to any operation that was deemed necessary to secure it. The patient was anesthetized, the cervix dilated and the uterine cavity explored with a large blunt curette, but nothing could be felt. The abdomen was opened and the uterus freely exposed. The organ was perfectly normal in size and appearance and free from any evidence of recent or old inflammation or of adhesions. Almost directly at the apex of the fundus there appeared to be a small opening through which I could pass a small probe into the body of the organ. It was now apparent that the hairpin was somewhere in the abdominal cavity. The hand was passed freely in among the intestines, and after a little exploration the lower end of the pin was discovered high up in the left side of the abdomen, the upper end very near the diaphragm. The bent upper end constituted something of a hook which caught in the tissues and would not come down without using force, which might seriously injure the intestine or omentum. A pair of broad ligament forceps was clamped on the lower end of the pin to steady it so that the hand could be withdrawn from the abdomen and a second incision was made at the inner curvature of the ribs, through which I grasped the upper end of the pin, which was pressed against the abdominal wall by the forceps from below. I found the hook on the upper end of the hairpin was entangled in the omentum, and it required some little manipulation to set it free. The pin was removed and the abdominal wounds tightly closed. The patient made an uneventful recovery.

---

* Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver, Dec. 28-29, 1903.

Case 2.—Several years ago a female doctor, whose practice consisted largely in producing criminal abortion, undertook the treatment of a case of supposed pregnancy. It was said that the woman had passed her menstrual period a few days. The doctor, in her testimony on the trial of the case, stated that she simply introduced into the uterus a soft rubber catheter in the evening, and the next morning on attempting to remove it found it had disappeared. There is reason to believe, however, that before introducing the catheter she had employed an uterine sound to explore the uterus. It was admitted that in searching for the catheter later in the day with a pair of long dressing forceps she caught something which she supposed to be the catheter, and on pulling it down she discovered—after eighteen inches of what proved to be small intestines were outside the uterus—the nature of the object which she had found.

A surgeon was called, but did not feel prepared to do an operation until the next morning. When the abdomen was opened the catheter was found among the intestines and eighteen or twenty inches of small intestine more or less separated from its mesenteric attachment. A resection and Murphy button were used, but the patient died on the operating table. It was claimed that the catheter itself perforated the uterine wall; on this point, however, we have no absolutely reliable information.

There can be no doubt that the uterine walls can be perforated with unexpected ease when in a normal condition, and with much greater ease in certain states of disease. It has been stated that the accident is of comparatively small importance and no serious results will come from it. While this may be true, at least to a certain extent, the admission must be restricted in view of the fact that of the recorded cases about 25 per cent. have proved fatal. Perforations with a sound which has been properly prepared for exploring the uterus will not generally be followed by serious consequences. Perforations with a curette are much more dangerous on account of the larger size of the instrument, and also on account of the possible laceration of the uterine tissue in the curetted area. If there is added to this an intrauterine irrigation the danger is greatly increased.

A few cases have come to my knowledge of perforation of the uterus by the curette followed by irrigation, and the operator, apparently not satisfied with the thoroughness of his procedure, packed a considerable quantity of gauze, which on postmortem was found in the abdominal cavity.

The treatment of accidental perforations of the uterus will depend on the nature of the instrument used. Unfortunately, the circumstances under which many of these accidents occur will often be a bar to proper treatment. In efforts at criminal abortion the ignorance or dishonesty of the operator will effectually interfere with a discovery of the condition of the patient until it is too late for an early operation to be of avail. In the cases which occur in legitimate practice the fear of censure or of malpractice, even if the accident is discovered at the time, will have its influence on the nature of the efforts made.

Dr. Brothers relates that in four cases of perforation with the curette in his own practice, three were successfully treated by rest and local application of ice, while in one the fundus was delivered through an anterior vaginal incision and the opening closed with catgut sutures.

Rosenfeld treated a case in a similar manner. Glaser and Kentman each mention a case of perforation with a curette which was treated by hysterectomy. Schwartz, while curetting after an abortion, perforated the uterus and packed the organ with gauze. The patient, after an attack of circumscribed peritonitis, recovered.

Queisner treated a case by tamponing the uterus, applying ice and giving opium. Guerard, Billroth, Man and Alberti each performed a laparatomy for the repair of perforation. In three of these cases the intestine had passed into the body of the uterus and in two the intestine was resected. All recovered.

If the perforation is small and made with clean instruments and if irrigation is not employed, rest and the application of ice will generally be followed by recovery with probably nothing more serious than a circumscribed peritonitis. If irrigation has been employed one of two courses of action will be necessary. If the infection is mild the treatment by rest and ice may be sufficient. If the infection is of a character to excite a septic peritonitis a vaginal hysterectomy with drainage will be indicated. In the milder form of infection there is danger of chronic inflammatory processes occurring in the pelvic connective tissue or peritoneum, leading to abscess formation and the train of sequences which so often attend chronic infection in this region, and will require the treatment usually demanded in such condition. If the perforation is more extensive or is made with a large size curette, the fundus may be delivered through an anterior vaginal incision and the wound in the uterus closed by sutures, or, as will happen in some cases of perforation resulting from a curettage preliminary to some operation on the uterus through the abdominal wound or by the vaginal route, the choice will be a suturing of the wound or a hysterectomy, as the conditions may indicate. As an immediate operation a hysterectomy is not often demanded unless the organ has undergone some degenerative change. It is certainly not good surgery to allow an opening of any considerable size to go unrepaired, not only on account of the danger of infection of the peritoneum, but on account of the danger of the intestine escaping through the opening in the uterus and becoming strangulated, as actually occurred in several cases.

Influence of Acute Infectious Diseases on Leukemia.—An article by Neutra, issuing from Schlesinger's clinic at Vienna (*Zeitft. f. Heilkunde*, xxiv, No. 11, 1903), discusses the probable cause of the reduction in the numbers of white corpuscles noted in leukemia during and after an intercurrent infectious disease. This reduction is always accompanied by an aggravation of the general condition, and the writer, Neutra, agrees with Fränkel that it is probably due to the disintegration of the white corpuscles by the toxins of the disease, and not to any improvement in the leukemic process. He has found 19 such cases on record.

THE CHEMISTRY OF THE MEDICAL SCHOOL.

J. H. LONG.
CHICAGO.

In the present condition of rapid growth and development in our medical schools, one of the vexing problems which has come up for solution is with reference to the kind and amount of chemistry which should be taught. It is evident to any one who takes the trouble to look that the methods and concepts of somewhat advanced chemistry are becoming more and more the property of the real medical worker, and to-day we hear from the clinician terms which but a few years ago were heard only in the laboratory of the investigator in pure chemistry. Beyond question, the medical man is called on to learn more chemistry and, seemingly, a new kind of chemistry.

Not long ago, in response to the question as to the kind of chemistry which should be taught to medical students, it would have been thought sufficient to answer "medical chemistry," and this somewhat vague term would have been looked on as covering all that is necessary. In giving the proper definition to the term the answer may be satisfactory, but what has usually been understood as medical chemistry is, in my judgment, very far from being the thing which the student needs most. The learning of isolated "tests" for the metals and acids of inorganic chemistry, or the memorization of a long rigmarole of complex organic formulas which may be recited parrot-like, does not constitute a kind of chemical training which is very valuable or very lasting. It brings little help in time of need. The chemistry which prepares for the understanding of the why is far more important than all this mechanical routine. The student must learn some tests, of course; he must, as a matter of necessity, learn how to recognize sugar, albumin, bile or indican, chlorids or phosphates, but this is the merest modicum of knowledge in medical chemistry, and of not much avail for the deeper understanding of things.

The modern physiologic and pathologic chemistry, although apparently concerned almost wholly with organic or organized substances, is really based largely on general and physical chemistry. This can be seen by a study of the journals rather than of the text-books, which still labor under the old limitations. The problems of immunity and toxicity are largely fermentation problems, and these are gradually finding their solution through the study of the inorganic ferments. It seems probable that formulas expressing the reactions of toxins and antitoxins may be written in accord with the mass-action laws; that is, that here as well as elsewhere reactions are found to take place in a way which may be accounted for through some of the generalizations of modern physical chemistry. The old question of the conditions under which uric acid precipitates before excretion is also being attacked from the standpoint of the mass-action law and the dissociation hypothesis, and already certain tangible results have been secured. The blood contains over 20 per cent. of organic substances and less than 1 per cent. of mineral matters or salts, and we are taught to attach much importance to the former and almost wholly overlook the latter. Yet the constancy or variations in the electrolytic components or ions of this 1 per cent. may have far more to do with the physical well-being of the body than the constancy of the 20 per cent. The means of maintaining constancy in these relations through the activity of the kidneys is very largely a problem of physical chemistry, and for a real understanding of the enormous literature which is accumulating on the cryoscopic and conductivity methods in the study of the blood and of the urine, one must go back to the first principles of the new general chemistry. We have acres of clinical experience proving the value of traces of lithium salts in the solution of uric acid concretions, yet a few lines and two or three simple equations in some of our recent special works and journals, have been sufficient to show the absurdity of the whole thing.

New ideas and new modes of expression from the terminology of physical chemistry are coming into the medical literature. We hear much of the toxicity of ions, the osmotic pressure of ions, the applications of the dissociation theory to the theory of disinfectants, etc. The work of Arrhenius and Madsen, referred to in a recent number of THE JOURNAL,[1] is a good illustration. These men have made an effort to apply the mass action and dissociation formulas to the Ehrlich serum antitoxin theory, and while the efforts may not be wholly consistent or successful, they are extremely interesting and suggestive, as they point out a method of controlling or testing the results provided for by the theory. Whether we accept the whole of the present ion theory or not, the terms employed have a meaning and have come to stay. The facts back of the terms are of still greater importance, and to understand them the student needs a thorough groundwork in inorganic and general chemistry. He must have correct notions of stoichiometry, which are best secured through the solution of chemical problems; he must have a practical knowledge of quantitative chemical relations, such as is most readily learned through work in volumetric analysis; he needs some work in elementary qualitative inorganic analysis; but not much, as the applications of such work in medicine are not frequent, and the disciplinary value of the short routine courses which can be given is not great. Finally, along with a general discussion of the more important elements and some of the compounds, he must have illustrated the principles of osmosis, diffusion, osmotic pressure, specific heat and the simple theory of indicators. This paves the way for the elements of organic chemistry, and the whole of the work is preliminary to the study of physiologic chemistry proper.

For the last work, then, which is everywhere admitted as essential in the medical course, the student absolutely needs the training in organic and general chemistry, including some of the most important concepts of that part which is now dignified by the name of physical chemistry. The course in organic chemistry need not be very long, but it must be concise and methodical. The work in Remsen's book is a good illustration as distinguished from that in some of the large manuals for medical students. In one case we have knowledge, in the other the appearance of knowledge. To suggest the value of organic chemistry in lines usually slighted by medical students recall the voluminous literature on the so-called diazo reaction of Ehrlich; a little accurate knowledge of the conditions of this reaction would have saved much useless speculation.

In fine, the medical student needs *modern* chemistry if he is expected to keep up with the advances in other lines and to profit by them. As medical school courses change, and general chemistry becomes a premedical study to be taken before the student begins his professional work, care will have to be observed by the authorities of the medical schools to see that the credentials brought cover the right ground. In the future of medicine the higher chemistry will undoubtedly play an important part. These lines are written mainly with the object of calling attention to the relatively great value of general and physical chemistry in this work.

TROPICAL CUTANEOUS MYIASIS IN MAN.

J. LEE ADAMS, Jr., M.D.
WASHINGTON, D. C.

At the present time, when the construction of an isthmian canal has turned the attention of medical men toward the tropical diseases of the Isthmus of Panama, I believe it will be of both scientific and practical value to bring forward a few observations I made on the isthmus, in regard to one of the most troublesome and common diseases of that locality.

Tropical cutaneous myiasis of man is caused by the *Dermatobia noxialis,* sometimes called the *Gusano-peludo* or *Muche.* Since 1749 numerous authors have treated the subject, but usually from the entomologic standpoint. Among the authors may be mentioned Linnaeus,[1] Say,[2] Clark,[3] LeConte,[2] Verrill, Goudot, Matas, Blanchard,[4] Railliet,[5] and others.[6] Blanchard's[4] article is the most extensive and complete. It contains a synopsis of the writings of thirty-one authors, extending from 1749 to 1889, and gives a detailed description of numerous larvæ which he has examined. Dr. Matas[7] published an article on the larvæ, which he took from the epidermis of two of his patients.

Cutaneous myiasis, as a result of the deposition of the eggs of the botfly, though common in animals of the temperate climate, is rare in man. In the tropics, no other disease is so common to man.

The *Dermatobia noxialis* belongs to the family *Oestridæ,* which includes the botflies. Various species of the family attack the horse, ox, sheep, rabbit, dog, monkey and man. In the horse, the disease is caused by the *Gastrophilus equi,* or botfly, the larvæ of which develop in the stomach and the intestines. In the sheep, it is due to the *Oestrus ovis,* and the larvæ develop in the nose and the adjoining cavities. In the ox, the disease is due to the *Hypoderma lineata* and *bovis,* and is a cutaneous myiasis. In the rabbit, it is due to the *Cuterebra cuniculi,* and results in a cutaneous myiasis. In man, monkey and dog of tropical America, it is caused by the *Dermatobia noxialis* and *cyaniventris,* and produces a cutaneous myiasis. Other forms of botflies, however, do produce a myiasis in man and dog, and at times the ox and sheep botflies attack man.

GENERAL DESCRIPTION OF THE PARASITE OF THE ŒSTRIDÆ FAMILY.

These parasites pass through three stages—adult. larval and pupa. The adults are heavy-bodied insects, somewhat resembling the fly and the bee. The larvæ are thick, fleshy grubs living a parasitic life in the bodies of various animals; they are composed of twelve segments more or less covered with rows of large black spines. The cephalic and caudal segments are provided with breathing tubes. The larvæ leave the host, then enter the earth, where they remain a certain length of time and finally emerge as flies.

DESCRIPTION OF THE DERMATOBIA NOXIALIS (FROM BLANCHARD).

Of the adult stage nothing is known other than it is a fly. "The larva is grayish white, pyriform in shape, 14 mm. long, 5 mm. thick, and is composed of seven distinct segments and a long caudal extremity. The anterior part of the first or caudal segment is invaginated and has hooked mandibles, which are scarcely visible. The second, third and fourth segments are covered with fine spines, scattered without order, and most abundant on the anterior half of the second segment. On the posterior border of the fourth segment there is a crescentic row of large black spines or hooks, nineteen in number, and confined to the dorsal surface. The anterior border of the fifth segment is capped by a girdle of large black hooks, twenty-five in number, which correspond dorsally with the half circle above. On the posterior border of this segment there is a dorsal demigirdle of nineteen hooks, similar to that on the fourth segment. The surface of the segment is covered with a small number of spines. The anterior border of the sixth segment has a girdle composed of twenty-three hooks, while the posterior border has a demigirdle of fourteen hooks, which are confined to the dorsal surface like the preceding demigirdle. The spines on the surface of this segment are few in number. On the seventh segment there is but one row of hooks, twenty-two in number, forming a complete girdle on the anterior border of the segment. The small spines and half girdles are missing in this segment. Following the seventh segment, the lines of division between the segments are very indistinct, the portion directly beyond is without spines or hooks, but what would correspond to the tenth, eleventh and last segments are covered with small spines." This description corresponds to the parasites found in my cases.

MODE OF INFECTION.

The method by which the parasite gains entrance to the body of its host is still clouded in mystery. There are, however, three theories. First: That the fly lays the egg on the skin, where it hatches and the larva bores its way into the skin. This is the theory most generally accepted. Second: The fly lays the egg into a wound previously made by her in the skin, where it hatches, and the larva bores deeper. Third: Recently it has been suggested that the eggs are carried into the mouth, where they hatch; that the larvæ attach themselves to the mucous membrane of the esophagus and pharynx, remaining there for a time to disappear, wander through the tissues of the body and finally locate in the subcutaneous connective tissues. This theory is based on the investigations of Dr. Curtice[8] in the cutaneous myiasis of cattle, a disease due to the *Hypoderma lineata,* a species closely allied and belonging to the same family as the *Dermatobia noxialis.*

A STUDY OF CASES.

In March, 1900, I was physician in charge of a party of seven whites and twenty-five natives, then exploring for a canal site at Caledonia Harbor, Isthmus of Darien. Of the seven whites, six became hosts of the parasites, and had a total of nineteen lesions. One white man who never took off his clothing escaped. Another, equally opposed to removing his clothing, had one parasite located in his ankle, which he constantly exposed to the attacks of the fly by going around in slippers and pajamas. Of the five remaining whites, all had at least two parasites, the writer having five. Among the natives, no record was kept as to the number of lesions, but it was noticed that, although they were in no sense immune from attacks of the parasites, they were seldom the hosts of more than one or two of the larvæ at the same time. The white members of the party were first exposed to the attacks of the parasites March 14, 1900. April 7, 1900, several complained of small boils, which later proved to be parasitic. The locations of the parasitic tumors in the whites were as follows: ankle 4, elbow 2, abdomen 3, thigh 2, calf 2, upper arm 2, buttocks 1, back 3.

The deposition of the eggs on the skin usually occurs while the individual is in bathing, as has been attested by numerous observers and victims. That the individual attacked is ever aware of the exact moment of the deposition of the eggs, must be viewed with doubt. Few of those stung in a tropical country pay any attention to such a trifling and common occurrence as a sting, much less remember the exact location with reference to the development of a boil sixteen days later. The period of incubation is from sixteen to twenty-three days.

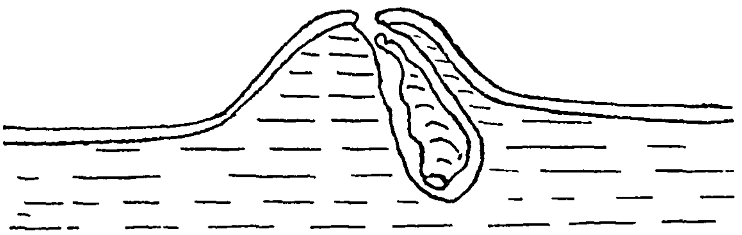

Fig. 1.—Diagrammatic drawing of parasitic tumor giving natural size of tumor and parasite after two and a half weeks' growth, and showing oblique position of parasite, capsule, central opening and relations.

The first indication of the disease is denoted by the appearance of small red papules, about the size of a pin head, each of which has a clear, well-defined, minute central opening. For about a week no symptom other than an increase in size of the papule with a corresponding increase in size of the central opening, is manifest. The patient usually imagines it to be, and the growth strongly resembles, a boil. On the seventh or eighth day after the discovery of the papule, a sharp pain, lasting a few minutes, occurs during the night, and is not unlike that which would be produced by a gimlet boring into the flesh. This is repeated at intervals of an hour or more. During the day no inconvenience results, but during each night the larva becomes more and more active as it increases in size and the tumor continues to grow. No one who has not been the host of one of these developing parasites can imagine the excruciating agony which it nightly produces. The tumor is now about the size of a twenty-five-cent piece, and the central opening one-sixteenth of an inch in diameter. At the end of a week of larval activity or two weeks from the first indication of papule, the patient becomes desperate and procedures for expulsion are at once instituted. In no cases under my observation has the larva remained in the subcutaneous connective tissue of man more than two and one-half weeks. The activity of the larva, the rapid growth of tumor, and progressive enlargement of the central opening, would lead to the supposition that if left alone it would make its own exit in a few days to enter the pupa stage. When expelled after two weeks' growth, the larva is from one-half to five-eighths of an inch in length. They differ in form according to the situations in which they develop. Those developing in portions of the body well covered with muscular tissue show a gradual tapering from the cephalic to the anal extremity, while those developing over bony prominences, like the ankle, have a marked cephalic bulb and a long caudal extremity.

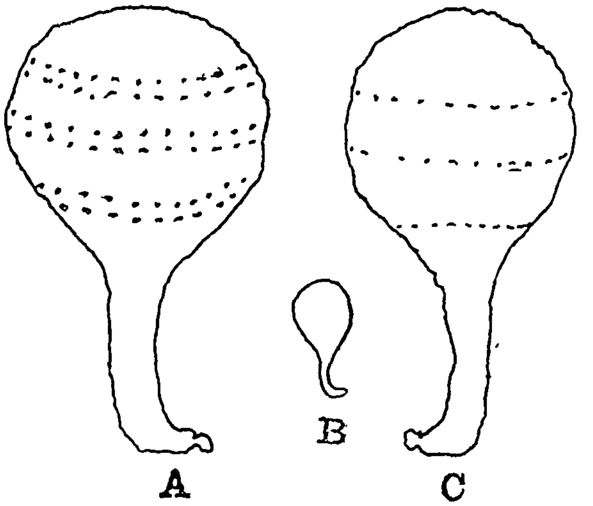

Fig. 2.—*Dermatobia noxialis;* larva. Shape of parasite when developed over bony prominences. A. Dorsal aspect showing double rows of spines. B. Larva, natural size. C. Ventral aspect showing single rows of spines.

TREATMENT.

As the parasite or larva is firmly attached to the tissue in which it is located, it is best and, indeed, necessary to institute some preliminary procedures, causing the parasite to lessen its hold before attempting manual expulsion. As an abundant air supply is necessary to the life of the developing parasite, this is shut off by closing the central opening in the parasitic tumor with adhesive plaster, cotton and collodion, postage stamp, tobacco leaf or other measures. After twenty-four hours the larva is thoroughly asphyxiated, the plaster is taken off, and only slight pressure is necessary to cause its expulsion. Ulceration, abscess and fatal results mentioned by some writers and attributed to this parasite are due to the improper treatment, and

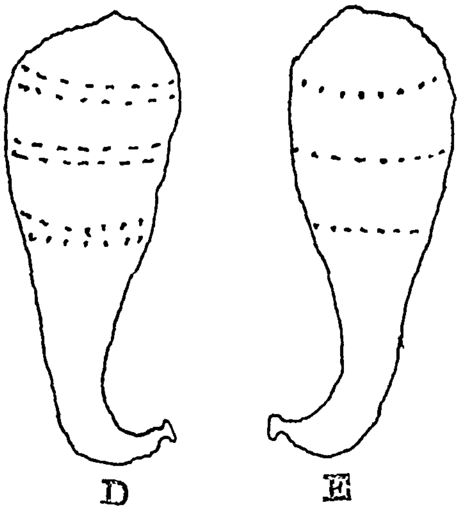

Fig. 3.—*Dermatobia noxialis;* larva. Shape of parasite when developed where muscular tissue is abundant. D. Dorsal aspect E. Ventral aspect.

are the result of forcible attempts at expulsion, without asphyxiation of the parasite. In these cases the larva is crushed and only partially expelled, the surrounding tissue is bruised and the capsule inclosing the parasite is broken down. The portion of the parasite remaining undergoes decomposition, germs enter and an abscess is the result.

SUMMARY.

1. Cutaneous myiasis in Darien is usually due to the *Dermatobia noxialis*.
2. Man and dog are host by preference. The *Dermatobia noxialis*, though not confining its attacks to man alone, can not be called an occasional parasite of man, as it attacks all who are properly exposed.
3. White-skinned races are more susceptible to the disease than the darker races.
4. The period of incubation is from sixteen to twenty-three days, from exposure to the development of the first symptoms.
5. Larvæ differ in shape according to anatomic location.
6. Grub or larva, if left alone, will not produce injurious results. Abscess and ulceration are the results of attempted expulsion without proper preliminary treatment.

CARCINOMA OF THE LUNG; PANCREATIC CYST.*

W. W. GRANT, M.D.
DENVER.

I report two cases of carcinoma of lung because of special interest attached to each—one recurring after an unusually long interval, and having at one time coincident tubercle bacilli, and while occurring several years ago is worthy of record; the other recently, and seemingly primary.

J. M. D., aged 48, Davenport, Iowa, school teacher. Personal and family history good. In February, 1894, had a dry cough. By fall the cough had increased and weight diminished. At this time Bierring, the pathologist at the Iowa University, found tubercle bacilli in the sputa. He went to Santa Fé, New Mexico; returned in the spring of 1895, having gained fifteen pounds, with the disappearance of bacilli. In June, 1895, he was examined by me in consultation with his brother, Dr. De Armand of Davenport. He had resumed his work, was pale, suffering much from dyspnea on slightest exertion, cough dry and expectoration slight. Slight circumscribed dullness was manifested about bifurcation of right bronchus, with some roughness in respiration. With this condition and history I thought, with all others who had examined him, that he was suffering from tuberculosis. In the fall of 1895 he went to Phoenix, Ariz., and lost weight and strength rapidly. Glandular enlargement of neck, axillæ and head, I was now informed by letter, was conspicuous, which caused me to suggest to his brother that the disease was malignant. He then informed me that six years before the left nipple was excised on account of a persistent ulcer, which was caused, it was believed, by a suspender buckle. This cleared up the history of the case, for it was undoubtedly a carcinomatous ulceration, though the interval of secondary infection was unusual.

He died June 2, 1896, after several months of extreme suffering from asphyxia. Postmortem by Dr. W. L. Allen of Davenport: effusion in both pleural cavities. Left lung in condition of atelectasis; right lung partially so. No evidence of tuberculosis. First bifurcation of left bronchus was surrounded by a fibrous mass, constricting the tube and completely excluding air. Same condition at same point of right lung, but permitting a little air to enter the lung. Pathological examination by Bierring showed the disease to be undoubtedly carcinoma. The coincidence of tuberculosis with carcinoma of lung or bronchial tubes has been repeatedly observed, but its existence and disappearance, as in the foregoing case, and the interval of at least four years from the excision of the nipple (no glands being removed) to the appearance of glandular infection and cough, make a history of unusual interest.

Shaw[1] reports a case of primary carcinoma of lung, and notes the similarity of tuberculosis in certain phases of the history. More recent cases are reported.

Mirklen and Girard[2] report a case constricting right bronchus, close to bifurcation. In thirty-one autopsies of carcinoma of lungs by Wolf, thirteen were complicated by tuberculosis. A great majority of cases of lung cancer are in men.

The second case is A. V. Rider, Davenport, Iowa, aged 57, railway engineer. He was in a collision in January, 1902, and suffered, he says, a fractured rib (left side), and from this he dates the beginning of his illness. May 14 he was seen by Dr. De Armand, who observed congestion of larynx and hoarseness, but did not regard his condition as serious. He continued to grow worse and Dr. De Armand examined him more thoroughly, and believed the case malignant. On June 4 he was seen by Dr. Allen. Paralysis of vocal cords and suffering from severe asthmatic symptoms, temperature normal and pulse 80. On June 22 I was passing through Davenport and was asked by Drs. De Armand and Allen to examine the man. He was suffering extremely from dyspnea, with loud crepitant and sonorous râles, and mucopurulent expectoration abundant. No bacilli; had lost thirty or forty pounds in the last three months. Dr. De Armand called my attention to a hard growth deep in the neck on left side of trachea, with fixed point in chest. No glandular enlargement and no pain. I had no doubt he was suffering from carcinoma of lungs or bronchi.

He died asphyxiated on June 25. Postmortem by Dr. Allen, who writes me that he removed a large, hard, irregularly shaped mass involving the bifurcation of bronchi, partially enveloping esophagus and aorta, with apparently some connection with connective tissue of anterior mediastinum. The lungs in the vicinity were involved and small nodules scattered through both lungs. There was also a prolongation of the growth into the neck on the left side. This was the mass felt on deep palpation of the neck on June 22.

Postmortem showed no disease whatever of stomach, but in the duodenum was a circular scar involving mucous and muscular coat with some narrowing of the intestine, indicating a perfectly healed ulcer.

There were no adhesions between costal and lung pleura, or other evidence that the railway accident had injured the lung at all.

The history and condition did not indicate a fractured rib. A section of the pathology was sent me, and examined by Dr. W. C. Mitchell with the following result:

"All of the specimens of tissue sent me proved to be carcinomatous, the areas surrounded chiefly by fibrous tissue; one specimen was evidently a lymphatic gland with numerous foci of carcinomatous cells."

---

* Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver, Dec. 28-29, 1903

[1] British Med. Jour., June, 1901.

[2] Presse Médicale, June, 1902.

I received no specimen of the intestinal lesion, but Dr. Allen writes that section of it did not reveal carcinoma cells. While cases of primary carcinoma of the lungs are now and then reported, they are rare, and I do not present this as a convincing one, yet unless there was some error concerning the duodenal lesion, it seems probable that it originated in the bronchial or lung tissue. The patient told me that he had never suffered pain, but about a year before the fatal illness some indigestion of short duration, which was, probably, caused by the lesion of the duodenum disclosed by postmortem.

I have nothing to offer for the relief of this very distressing condition, whether primary or secondary, unless it should come from the application of the Roentgen rays.

For the clinical history of the following case of pancreatic cyst, prior to being referred to me, I am indebted to the attending physician, Dr. T. B. Gormly of Windsor, Colo.

Mrs. C. C. L., aged 37, wife of a farmer, youngest child 10 years old. Personal and family history good. Never before had any serious illness. Was taken suddenly March 3, 1903, with severe epigastric pain, for which a hypodermic of morphia was given. Temperature normal, pulse 120. Patient very fat, weighing over 200 pounds. Next seen April 4, when pulse was 90 to 108, temperature 100.5, and pain and tenderness in the epigastrium, and extending to the left, persisting. Seen again April 19, suffering much from gas in stomach and indigestion, with occasional vomiting; pulse 120, temperature normal, but losing strength and flesh rapidly. Palpation showed tumor in the left upper quadrant. Stomach rejected food and rectal alimentation commenced and continued from this date, during which time tumor increased in size; temperature varied from 100 to 100.5, being on one occasion 101, and pulse 115 to 125. On May 8 advised exploratory section. On May 18 patient reached Denver and was placed in my charge. At this time her temperature was 97.5, pulse 104. A large, smooth, oval, immobile tumor was easily outlined, occupying epigastrium and left hypogastrium, extending downwards one inch below horizontal line from the umbilicus, and one and a half inches to right of middle line from ensiform cartilage to umbilicus. The abdominal wall was so thick from fat that fluctuation could not be detected. Monro says: "Almost all patients are markedly fat."[3]

No diarrhea, no previous examination of urine, but no sugar nor albumin now in urine. Blood examination by Dr. W. C. Mitchell showed it to be practically normal.

She has had no fall nor injury. No jaundice, though a slight staining of the conjunctiva exists. No history of gallstones. From a careful consideration of the clinical history, and the differential diagnosis as to adrenal, kidney, gall bladder and omental cysts, and especially hydatid of the left lobe of liver, I concluded it was a pancreatic cyst. This opinion was shared by Dr. J. N. Hall of Denver. At the same time it must, at present, be admitted that no absolutely positive diagnosis can be made without operation. Aspiration for diagnostic purposes is often more dangerous than incision, so I determined to operate, and May 23, at St. Luke's Hospital, made an incision three inches long in the middle line from umbilicus upward. The wall was nearly three inches thick in fat. The sac was adherent to the abdominal peritoneum, which was quickly opened, and at least a gallon of chocolate-colored liquid was evacuated. Further examination with fingers and long dressing forceps showed that the cavity included the lesser peritoneum, extending to the left lumbar costal angle. The sac was thoroughly washed out with warm salt solution, and a six-inch rubber drain half an inch in diameter with shoulder at inner end, inserted. There was a free serosanguinolent discharge, with some pus, for a day or two. The discharge diminished rapidly and changed, being more purulent with thick dark-colored material, which I regarded as due to sloughing, and which ceased at end of first week. The parts were now contracting and closing on the tube tightly so it was partially withdrawn, and three inches cut off. The day after operation the temperature was 100.5 and pulse 108. From the third day until date of discharge, on June 16, twenty-four days after operation, the temperature ranged from 97.5 to 98.5 and pulse from 80 to 100. Before discharge a small short drainage tube was inserted, and the wound closed permanently in ten days. She suffered greatly from dyspnea before operation. The digestive and gaseous disturbance continued severely for two months. Her digestion is now very good and strength and weight have improved in marked degree, and except for tingling and some numbness in hands and feet, which is disappearing, she writes me that she considers herself quite well. The contents of the sac were examined and a large number of fat, blood and pus cells were noted. Trypsin was absent, as usual in large cysts. Feces were not examined. The suggestion to open the cyst in the costo-vertebral angle, because shorter and more direct, and more dependent, therefore favoring more perfect drainage, is a good one, and in a future case I should do it, but should make the anterior "incision" first, both to confirm the condition and to facilitate the posterior operation, closing the anterior incision at once, or within a few days.

The cause of pancreatic cyst is doubtless due usually to obstruction of the pancreatic duct by stone, as suggested by Senn, and endorsed by some other observers; the obstruction being due to calculus or interstitial pancreatitis. Most writers agree that hemorrhage is not a primary cause of cyst, though admitting that it is at least a secondary phenomenon, and itself may be due to obstruction of one or both pancreatic ducts. Stone in the common bile duct, by closing the duodenal orifice of the pancreatic ducts, is an admitted cause. Lloyd says that effusion into the lesser peritoneum has been mistaken for pancreatic cyst, but the mistake is improbable when one remembers that this effusion, independent of pancreatic disease, is rare, and is due usually to injury, and the injury which produces this will generally damage the pancreas. It is entirely improbable from its location that the pancreas can be seriously injured without affecting other parts, and effusion into the lesser peritoneum as a consequence of pancreatic disease is common. The tail of the organ is believed to be the most common seat of cyst, and the head more frequently affected in carcinoma. Cases of cyst have been reported which presented no evidence of obstruction by calculus. No satisfactory evidence of stone exists in the case I report. The belief that inflammatory conditions will result in hemorrhage and cyst is justifiable.

Opie has demonstrated that the injection of healthy bile into the pancreatic duct of animals will produce hemorrhage and fat necrosis. Infected gall bladder and ducts will, through the pancreatic duct, infect the pancreas. Hemorrhage is common in icteric cases, and the statement that pancreatic hemorrhage is more common when the jaundice is due to pancreatic obstruction than when it is due to gallstone obstruction, is a rational one. Blood condition is the probable explanation. Though diabetes is common without disease of the pancreas, Opie has demonstrated that total destruction of the pancreas is followed by diabetes, but partial destruction is not. Investigation tends to prove that the latter is due to the fact that the islands of Langerhans, certain secretory cells of the gland, are not destroyed. When diseased or destroyed, diabetes results.

---

[3] Jour. A. M. A., 1902, vol. xxxix, p. 809.

Robson and Moynihan state that free fat in the feces is more common than sugar in the urine, the latter not being present in most of the reported cases, and when found, Flexner shows, was only in the first few days of the history. Robson says with the history of indigestion, sugar in urine, fatty diarrhea, loss of flesh and bronzing, pancreatic disease exists; also that acute epigastric pain, followed by a circumscribed inflammation, tenderness and tumor, with indigestion, is strongly indicative of pancreatic cyst. Without an intelligent clinical history the diagnosis is guess work.

A review of reported cases and literature shows convincingly that the disease is essentially surgical, and that delay in operating is as dangerous and fatal as in appendicitis. The gangrenous cases can only be saved by promptly opening the abdomen and draining. Formerly and recently reported cases[4] by Woolsey, which seemed unfavorable for operation, amply attest this.

The general suggestion of treatment of the sac is to dissect it out if small, but in the case of a large sac this attempt is manifestly unsafe and dangerous. The extensive adhesions make it exceedingly difficult and extravasation of pancreatic juice or septic material would probably destroy the patient.

Several patients have died from this treatment; while to attach the sac to the abdominal peritoneum if not already adherent, and drain is safe, and undoubtedly the best treatment of the large cyst. Pancreatic juice out of its normal channel produces, as is well known, fat necrosis. Pancreatic disease often simulates intestinal obstruction, and the statement may be safely accepted, that if the surgeon opens the abdomen, and does not find obstruction or perforation of the stomach, but does observe fat necrosis, the pancreas is, in all probability, the source of the trouble. The small number of cases reported, and the limited experience of the profession in the treatment of this disease, will, I trust, secure your indulgence of the extended remarks.

TAHITI FROM A MEDICAL STANDPOINT.

N. SENN, M.D.

Head of the Department of Surgery, Rush Medical College, in Affiliation with the University of Chicago

CHICAGO.

(*Concluded from p. 889.*)

PREVAILING DISEASES.

The average temperature of the inhabited part of the island, which can not be much less than 78 to 80 F., has a relaxing influence on the natives, and much more so on the small contingent of whites. The Europeans and Americans find it necessary every three to five years to seek for a few months a cooler climate to restore their energies and vigor. The government officials and officers are not obliged to serve for more than the same length of time, when they are relieved. It is this relaxation which, to a certain extent at least, is responsible for the great mortality of comparatively mild acute infectious diseases and the acuity of pulmonary tuberculosis among the natives. Tuberculosis of the lymphatic glands, skin, bones and joints appears to be extremely rare. The moisture-laden atmosphere and the suddenness with which the cool land and ocean breezes set in after the heat of the day is conducive to the development of rheumatic affections, which are prevalent in all parts of the island, more especially during the rainy season in midwinter. The same can be said of bronchial affections and pneumonia.

The free and unrestrained intercourse among natives accounts for the rapid spread of tuberculosis and acute infectious diseases among the entire population and from island to island. The sanitary commission, now engaged in efforts to reduce the mortality of the natives, will establish rules and regulations which will have for their object the prevention of dissemination of acute as well as chronic infectious diseases, will undoubtedly accomplish much toward the preservation of the race, but these officers will meet with stubborn opposition on the part of the natives when attempts are made, in their interest, to curtail their personal liberties. The ties of relationship and friendship among the natives are very strong, and become most apparent in case of misfortunes and sickness.

Smallpox breaks out almost every year and claims its share of victims. Vaccination is supposed to be compulsory, but the natives are inclined to escape it. Vaccination is done at the Military Hospital for all natives who can be induced to submit to it. Like in all tropical countries, tetanus is prevalent. The small native pony is found everywhere, and as the rural natives are all barefooted and spend much of their time in the jungles in impregnating the flower of the vanilla bean and gathering fruits, wounds prone to infection with the tetanus bacillus are of frequent occurrence. Malarial diseases are comparatively rare, although the plasmodium-carrying mosquitoes are numerous and aggressive, and children in the country districts are nude and the men limit their clothing to the wearing of a breechcloth. No case of typhoid has been known to have originated in the island. The exemption from this disease, so widely spread over the entire globe, in this island is due entirely to an abundant supply of the purest drinking water supplied by the numerous mountain streams. Nearly all of the inhabitants live on the coast, near the outlet of a brook or stream, where consequently there is no danger whatever of water contamination. I found three cases of typhoid fever in the Military Hospital, members of one family, who had been brought there from one of the neighboring atoll islands.

Varicose veins, varicocele and hydrocele are very common. The absence of anything like a large ulcer in many cases of large and numerous varicose veins I attributed to the toughness of the skin of the bare legs. Venereal diseases are widespread throughout the entire island, and more especially in Papeete and the nearby larger villages. Syphilis appears to pursue in the natives a mild course, as I found few instances of the ravages of the remote results of this disease. I only saw one saddle nose caused by tertiary syphilis. Leprosy is not as prevalent as in the Hawaiian Islands, but isolated cases are found in nearly all of the islands belonging to this group, being more prevalent in some than in others. Segregation has never been attempted. The lepers mix freely with the members of their family and neighbors and are not shunned. I was informed that many of the lepers, much disfigured by the disease, seek an island where many of these unfortunates have founded a colony for the purpose of escaping from public gaze. Elephantiasis in its worst forms has taken a firm hold on the natives, especially the inhabitants of the nearby island of Moorea. There this disease can be studied in all its stages, from a slight enlargement of one of the extremities to colossal swellings, which, when the upper and lower extremities are affected at the same time, make it necessary for the patient to crawl on his hands and feet in dragging himself from place to place. Regarding elephantiasis as it exists in Tahiti and the other islands of the French colony, I will make use of a few extracts taken from a valuable paper on this subject by Dr. Lemoine, recently in charge of the Military Hospital, and published in one of the government reports.[1]

---

[4] Annals of Surgery, November, 1903.

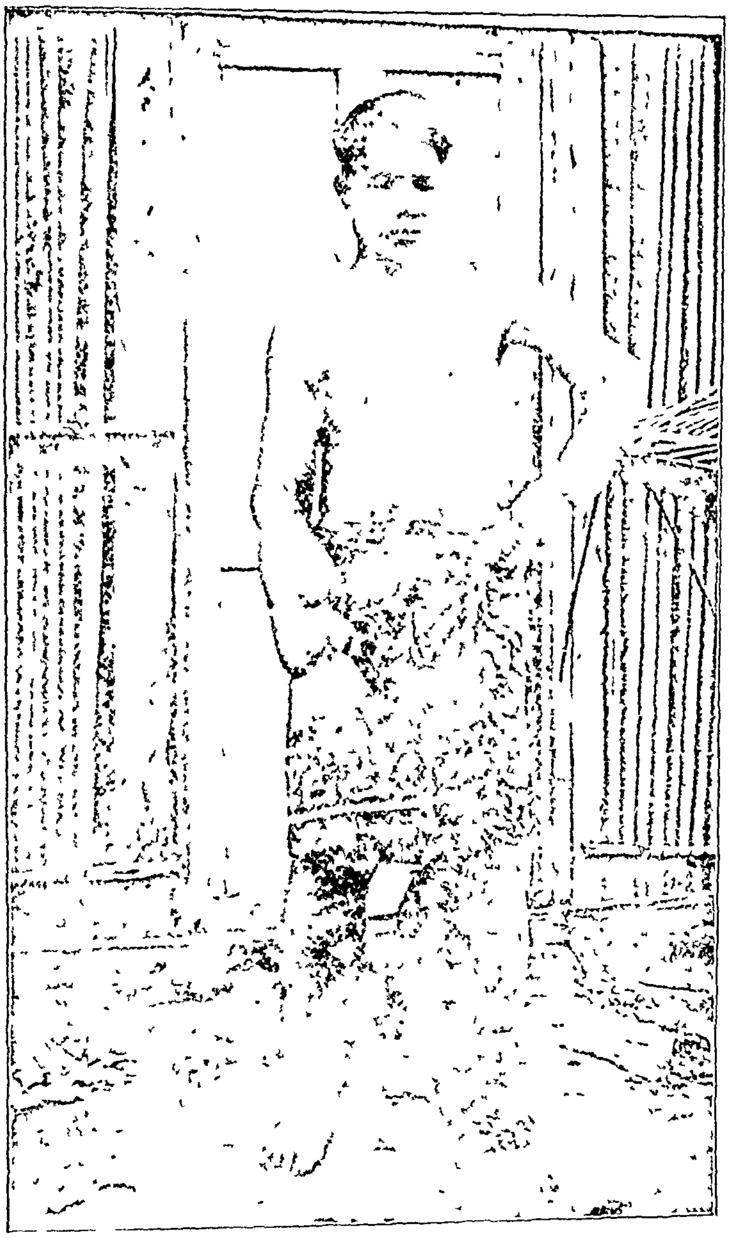

Fig. 3—Tahitian. Elephantiasis of all extremities

According to Lemoine, who has seen much of this disease in Tahiti and surrounding islands, it may affect most regions of the body, and not infrequently makes its appearance as an acute affection with all the symptoms characteristic of lymphangitis, including quite a violent continued or remittent form of fever, which lasts two or three months. The acute form is, almost without exception, complicated by synovitis of the joints of the affected limb, which he regards as almost pathogenic of the disease, differentiating it from ordinary forms of lymphangitis. After the subsidence of the acute symptoms and in the chronic form the disease is essentially a chronic lymphangitis, accompanied by marked enlargement of the veins. According to his observations the regions most frequently involved are the lower extremities, external genitals, and lastly, the hands and forearms. Last winter I was given an opportunity to see, at the hospital and poorhouse at Antigua, West Indies, 90 cases of elephantiasis, and not in a single one of them did the disease involve the upper extremity, while in the French colony of the South Seas this is not infrequently the case. I do not know that a satisfactory explanation has ever been given why the disease should behave so differently in the two groups of islands. Lemoine, as well as other writers on elephantiasis, has seen the disease become stationary by the removal of the patients to a colder climate. Europeans become susceptible to elephantiatic infection after a prolonged residence in tropical countries Lemoine does not agree with Manson, who believes that elephantiasis is caused by the filaria sanguin and suspicions that the essential etiologic factor is a yet undiscovered microbe. He made blood examinations night and day of patients under his care, and was unable to constantly detect the filariæ in their embryonic state in the peripheral blood, and consequently claims that the presence of filaria in the organism is not an infallible diagnostic indication, and that their abundance is not proportionate to the intensity of the disease.

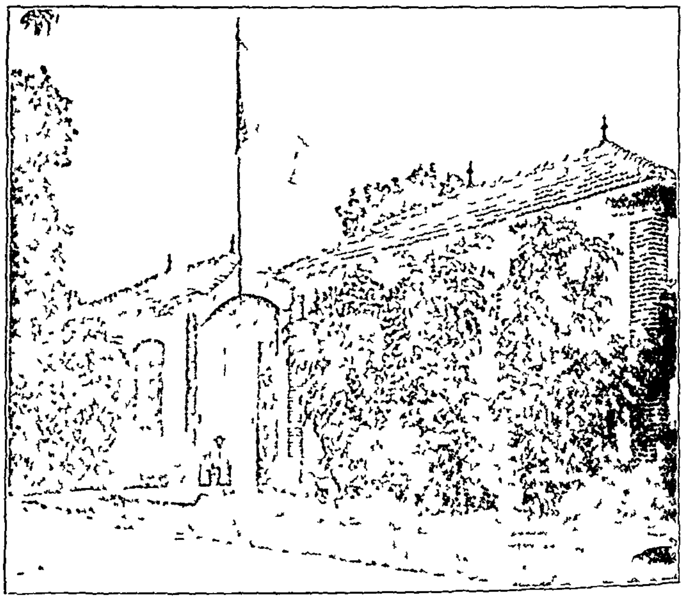

Fig 4—Military hospital at Papeete

The fact that the elephantiatics improve in colder climates he regards as another proof that filariasis is not the essential cause of the disease. In a number of cases extirpation of the infiltrated enlarged lymphatic glands was followed by decided improvement, and in the case of a Tahitian the improvement remained at the end of two years. He has also operated on a number of cases by partial excision of the mass, first on one side of the limb, then the other, with decided benefit to the patient in most of them. In some cases deep incisions through the entire thickness of the indurated mass afforded relief and resulted in diminution of the size of the swelling. He relates the details of the case of a native, 50 years old, the subject of elephantiasis of the lower limbs, that he operated on in two stages several weeks apart, removing first a large section from the anterior and later from the posterior part of the swelling, and as shown by the accompanying illustrations in the report depicting the condition of the limbs before and after operation. with an excellent result. However, in some of the cases the results could not be maintained for any considerable length of time. In making the excision, the superfluous skin is excised with the underlying indurated tissues, and the skin margins reflected for some distance in order to afford sufficient room for a more liberal excision of the deep tissues.

---

[1] Quelque's opérations palliatives applicables à l'éléphantiasis des arabes pratiquées a'Tahite, par M le Dr Lemoine, Médecin Major 1pr Classe Troops Coloniales

In one case, that of a woman 38 years of age, the patient died two weeks after the second operation. Death was attributed to loss of blood and the debilitated condition of the patient when she entered the hospital.

In another case, a Tahitian, 35 years old, affected with elephantiasis of all limbs and the external genitals, he operated successfully on one of the upper limbs, the seat of an enormous swelling below the elbow. The excised mass weighed 15 kilograms. Owing to the large size of the swelling, the operation proved one of great difficulty, and owing to the tension incident to the approximation of the margins of the flaps the sutures cut through and the wound healed by granulation. At the second operation nearly the entire mass was removed, with the result that the wound healed after a prolonged suppuration and the patient was relieved of the incumbrance caused by the great weight of the swelling. The relief afforded induced the patient to request additional operations for the removal of the swellings involving other regions of the body, but as the surgeon soon after left the island his desire could not be gratified.

The paper of Lemoine is summarized by him in the following conclusions:

1. Operate before extensive muscular degeneration has taken place and prepare the limb with the utmost care to insure asepsis.

2. Study carefully the anatomic relations of the swelling and operate where the swelling is narrowest.

3. Select the skin best adapted for flap formation with which to cover the wound. Transverse flaps are more likely to survive than lateral flaps. The best plan to make the flaps is to shape them so that the wound can be sutured in the form of a Maltese cross.

4. The median flaps should be cut first obliquely from without inward, taking care to make them sufficiently thick for the excision of the mass and the cutting of the lateral flaps; make a longitudinal incision through the middle of the mass and calculate carefully the extent of the diseased tissue to be excised. The lateral flaps should be thickest at the base and well supplied with blood vessels.

5. To be absolutely sure of asepsis, avoid unnecessary manipulation and clamp rapidly all the bleeding vessels as they present themselves; tie all the veins with catgut and drain at the most dependent points.

6. Suture carefully with catgut for the deep and horsehair for the superficial sutures so as to secure the most accurate coaptation of the flap margins. as the sclerosed skin does not apply itself readily to the wound surface.

7. Avoid irritating antiseptic dressings, as they are productive of dermatitis in tropical countries, and especially if applied on skin diseased and badly cared for.

8. The first dressing should be aseptic, light and made to exercise gentle, uniform pressure by bandaging.

HÔPITAL MILITAIRE.

The Military Hospital at Papeete is the only one in the French colonial possession of the Society Islands, numbering 168 islands and containing a population of 30,000, of whom 11,000 live in Tahiti. As some of these islands are more than 100 miles apart it is somewhat strange that the French government has not taken earlier action in establishing small cottage hospitals in a number of the larger islands, as in the case of severe injuries or sudden illness the natives of the distant islands are not within reach of medical aid and the transportation by small schooner or canoes of a sick or injured person to Tahiti from the far-off islands is necessarily slow and in many instances dangerous. The sanitary commission now stationed in the islands will, it is to be hoped, act promptly in remedying this defect in the care of the sick natives.

On the voyage from San Francisco to Tahiti I met Mr. George R. Richardson, a native of Springfield, Mass., who had lived with his native wife on the little atoll island Kaukuaia of the Tuamotu group, 168 miles from Tahiti, for the last thirty years. He was suffering from carcinoma of the esophagus, and was returning from San Francisco, whither he had gone for medical advice. His little island had a population of 150, and during his residence there he had never seen a physician, although the inhabitants were frequently in need of medical services, owing to frequent visitations of epidemic diseases and the prevalence of pulmonary tuberculosis. His native wife gave birth to sixteen children, all of whom he delivered himself, and strangely without any mishap either to mother or child. What happened on that island must have happened on the many other distant islands under similar circumstances.

The Military Hospital at Papeete is an old structure of brick and cement, situated near the western limits of the city in a large square yard inclosed by a high stone wall, surmounted by a crest of fragments of glass, which imparts to the inclosure a prison-like appearance, the severity of which, however, is much relieved by beautiful tropical trees, shrubbery and flowers in front of the entrance and in the court yard. The hospital proper comprises seven buildings, only one of which is two stories high. The hospital has accommodations for 40 patients. The officer's rooms contain two beds each; the remaining space is divided into small wards for privates and civilians. In one ward, the windows of which are strongly barred, are kept the prisoners, and another small ward is devoted to obstetrical cases. The rooms and wards are well ventilated and clean, the beds comfortable; the hospital furniture otherwise is scanty and antique.

The drug room is large, richly supplied with large jars, mortars of all sizes, herbs, roots and a complete and complicated outfit for making infusions, decoctions and tinctures, which reminds one very vividly of an apothecary shop of half a century ago. This department is in charge of a pharmacist who, besides mixing drugs, does some chemical and bacteriologic work in a small and imperfectly equipped laboratory. The operating room is an open passage way between two adjoining wards. and all it contained suggestive of its use were an operating table of immense size and decidedly primitive construction, and a tin irrigator suspended from the wall, to which was a long piece of rubber tubing of doubtful age. The hospital is well supplied with water, and contains a bathroom, a shower bath and modern closets.

The hospital is in charge of the government physician, who is always a medical officer of the colonial troops detailed for this special service, usually for a period of three years. The present incumbent is Dr. Brunati, a naval surgeon, who is about to be relieved by his successor.

From some reports I gleaned that on an average this institution takes care of about 350 patients a year. At the time of my visit the number of patients did not exceed 15, among them one in the prison ward. All of the patients were the subjects of trifling affections. The patients are being cared for by three Catholic sisters and orderlies as they are needed. Charity cases are admitted gratuitously; private patients pay from 6 to 15 francs a day.

PHYSICIANS OF TAHITI.

There are only two educated physicians in Tahiti, Dr. Brunati, the government physician, and Dr. Chassauiol, a retired naval surgeon, the latter the only private practitioner in the whole group of islands. The government physician is privileged to practice outside of the hospital, and from this source he receives the bulk of his income. These government physicians are by no means low-priced practitioners, as is shown by one instance that came to my knowledge, when a native of limited means was charged $100 for a circumcision for phimosis. As these two physicians are the only ones in the whole archipelago constituting the Society Islands, the French colony of the Pacific, it requires no stretch of the imagination to realize that until the present time the French government has not made adequate provisions for their subjects requiring the services of a physician.

The Tahitian has not lost his faith in the native doctors, who, without any medical knowledge, practice their art. These men, with a local reputation as healers of disease, are to be found in nearly every village; they are well thought of and are influential members of society in their respective communities. Like the medicine men of our Indians, they make use of roots, bark and herbs as remedial agents, and the natives, like many of our own people, have more faith in this mysterious kind of medication than modern, concentrated, palatable drugs prescribed by the most eminent physician. To the credit of these native medicine men it must be said that they give to all afflicted who apply for treatment not only their services, but also the medicines without any expectation of reward or even the gratitude of their clients.

LARYNGECTOMY FOR CANCER.

H. H. GERMAIN, M.D.
Surgeon to Out-Patients' Department, Carney Hospital; Instructor in Surgery and Anatomy, Tufts Medical School.
BOSTON.

Previous to 1888 the death rate for laryngectomy was very high. According to Sendziak,[1] who has collected the largest number of cases, the mortality is 35 per cent. for all cases up to 1897. If we now look at the cases operated on from 1888 to 1898, we find that the death rate has fallen to 14.5 per cent., with a corresponding fall in the number of recurrences—11.2 per cent. as compared with 30.3 per cent. This marked improvement has been due to the new methods which aim to avoid sepsis and to do away with aspiration pneumonia. These two conditions have been responsible for the majority of the fatal cases, while reflex inhibition of the heart through the superior laryngeal nerve and death from vagus degeneration deserves mention. Recurrence is less frequent because of early and more radical operating with regard for the lymphatics.

The first step in advance in operative technic was made by Bardenhauer.[2] He sutured the pharynx wall after removing the larynx, to avoid contamination of the wound by saliva, decomposing food, etc. Poppert[3] copied Bardenhauer's procedure and added a second layer of stay sutures, while Rotter[4] strengthened the pharyngeal sutures by sewing the divided muscles over in the median line. To prevent the entrance of wound secretion into the trachea, Gluck[5] separated the latter from the larynx, and turning the tracheal stump forward, sewed it into the lower angle of the wound. Foederle,[6] after total larynx extirpation, fastened the stump of the trachea to the hyoid bone, thus preserving the continuity of the trachea with the upper air passages. His patient made an uneventful recovery, and was able to leave the hospital in two weeks. Von Hippel's experience with this operation was unfortunate. In his case the upper end of the trachea became gangrenous from tension and infection, though the patient recovered after two months' illness. In view of this circumstance, few surgeons will care to operate in this way, and as far as I have been able to discover, there are only the two cases in the literature of this subject.

Opinions differ concerning the feasibility of preliminary tracheotomy. Delavan speaks in favor of it. Kocher[7] advocates tracheotomy at the time of the major operation, while Keen[8] omits it altogether. Davis[9] speaks strongly in favor of this procedure, and says that by it the trachea is fixed to the surrounding tissues, and this prevents the riding up and down of the stump in the wound that occurs when the larynx and trachea are separated. His patient died from infection, primary about the sutures uniting the stump to the skin. No preliminary tracheotomy had been done, and the constant motions of the tracheal stump prevented union and predisposed the tissues to infection. A similar case occurred in the experience of Delavan. The only objection to preliminary tracheotomy is that the patient is subjected to two operations, with several days intervening and the resulting anxiety.

Local anesthesia finds more favor abroad than in the United States. Kocher advocates cocain for all laryngeal operations. Davis used eucain in his case. Most American surgeons prefer chloroform, and there can be no doubt that conditions are more comfortable for all concerned with a general anesthetic. Whatever anesthetic is used, the superior laryngeal nerve should be cocainized to avoid reflex inhibition of the heart.

The epiglottis may be removed with the larynx or left *in situ*. Some operators remove it as a routine measure, on the ground that it may be the site of recurrence. Its removal certainly offers no difficulty.

Whether the coracoid is excised or left in place must be decided at the time of operation. Where the coracoid is removed, patients are said to swallow better. This has not been borne out in my case, where I left the cartilage in place and the patient has no dysphagia. Formerly the tampon canula was regarded as a necessity in performing laryngectomy, but it is now gradually falling into disuse in favor of the simpler and equally efficient Trendelenburg-Rose position, which is the Trendelenburg position with the head thrown sharply back. This exposes the trachea in the best possible manner, and prevents the inflow of blood more certainly than does the tampon canula.

---

[7] Kocher: Operative Surgery, 1903.

[8] Keen: Annals of Surgery, 1899.

[9] Davis: Annals of Surgery, vol. xxxiii.

Briefly stated, the present operation seems to be divided into two steps, 1, preliminary tracheotomy; 2, after a few days or weeks laryngectomy in the Trendelenburg-Rose position. Cocainization of the superior laryngeal nerve is to be remembered. Primary suture of the pharyngeal and esophageal wounds saves the patient weeks in convalescence, while turning the tracheal stump forward and sewing it in the lower wound angle obviates the necessity of a permanent canula, and in a great measure prevents aspiration pneumonia. That these are improvements over the old methods there can be no doubt, and a glance at the more recent statistics seems to convince one in that opinion.

Gluck[5] reported 34 cases with 31 recoveries, a mortality of only 8.5 per cent., while Graf,[10] of Von Bergmann's clinic, reported 9 cases with one death. Lincoln[11] reported seven cases with one death; the death resulted from vagus degeneration after two weeks.

Concerning the after-care of these cases there is little to be said. Rectal feeding is usually necessary for a few days, followed by cautious esophageal feeding, then liquid and solid food in the order given. In view of the cases of Goldstein,[12] Solis-Cohen[13] and Schmid,[14] the artificial larynx would seem to be unnecessary. In these patients a distinct pseudo-voice was developed, and Goldstein's patient could sing a simple song of more than two tones. In all of these cases there was no connection between the trachea and the pharynx, and it was thought that the air necessary for the production of sound was collected in a dilatation of the pharynx and probably the upper fourth of the esophagus. The slit representing the new larynx was formed between the tongue and the posterior pharyngeal wall. That partial laryngectomy is the operation of election there can be no doubt, but certainly the last decade has served to rob total laryngectomy of many of its terrors.

Mrs. —, aged 33 years, was seen in consultation with Dr. Plummer, Oct. 31, 1902. Her family and past history were negative. Present illness dates back about five years. During this time she has been hoarse and sometimes dyspneic. These symptoms have been worse in the past month, with marked increase in dyspnea during the last two weeks. At times she is very cyanotic, but has no dysphagia, no loss in weight, no history to indicate tuberculosis or syphilis. She has been treated by several laryngologists for "papilloma of the larynx" without relief.

Physical Examination.—She is well developed, well nourished and obese, with a short fat neck. Examination, except as to larynx, is negative. Urine and sputum are negative. With the laryngoscope Dr. Plummer was able to see a tumor which apparently had its base near the lower part of the epiglottis and extended backward between the false cords, covering the true cords. The tumor showed several ulcerations on its surface, and there were also ulcers on the aryepiglottic folds and on the base of the epiglottis. The vocal bands showed good motion with a fair amount of breathing space between them.

In the differential diagnosis tuberculosis, syphilis and malignant disease were considered. The first mentioned could almost be certainly excluded by the negative sputum examination, so that syphilis and malignant disease were most prominent in our minds. Since there was fair breathing space between the cords we decided to try the effect of antispecific treatment, so mercury biniodid, gr. 1/16 t. i. d., and potassium iodid, gr. 10, to be increased to gr. 30 t. i. d., were ordered.

On the following day the patient's condition was worse. She had had several bad attacks of dyspnea, was very apprehensive and slightly cyanotic. Therefore, tracheotomy seemed advisable while her condition was good, as the short fat neck promised a difficult operation under the most favorable conditions.

Tracheotomy.—Cocain ¼ per cent. Median incision one and a half inches long. The coracoid could not be palpated on account of the thick layer of fat. Dissection carried down to trachea, which was opened below the second ring. Tracheotomy tube inserted. Operation was rather long—20 minutes.

For several days there was considerable trouble with the tube, which was too short and kept jumping out of the trachea. When this occurred air was pumped into the tissues of the neck and the resulting emphysema and dyspnea were very alarming. The problem was finally solved by substituting a piece of a No. 28 F. rubber catheter for the canula until the longer silver canula was made. Some bronchitis followed the operation, lasting for about eight days. The antisyphilitic treatment, above mentioned, was carried out for eighteen days. At the end of this time, there was considerable increase in the size of the tumor, with some sloughing. Repeated attempts to obtain a microscopic specimen with laryngeal punch forceps failed to yield anything but sloughing tissue. The larynx was now closed by the tumor and by edema. There was no voice, and apparently no air came through the larynx. The conditions being in every way worse, exploration was decided on.

Laryngectomy.—Nov. 19, 1902, chloroform was administered in the Trendelenburg-Rose position. The tracheotomy wound was extended up to the hyoid bone and joined at the upper end by a transverse incision which reached to the anterior border of the sternomastoid muscles on either side. The sternohyoid muscles were retracted and the thyroid cartilage was cocainized and divided in the median line with scissors. The larynx was found filled with friable growth. As the cartilage was involved, it seemed best to remove it. The sternohyoid muscles were then severed just below the hyoid bone, while the thyrohyoid and sternothyroid muscles were separated from the cartilage at their insertions. The thyrohyoid membrane was now divided on the left and the left half of the thyroid cartilage with corresponding vocal band and arytenoid were removed *en masse*. Beginning above, the thyrohyoid ligament, stylopharyngeus, inferior constrictor and cricothyroid muscles were divided in turn. In a similar manner, the right half was removed with the epiglottis. This was readily accomplished by turning the cartilage downward and outward as the structures were severed. I then tried to bring the trachea with the coracoid forward in order to sew the stump to the skin in the lower wound angle, but found the trachea too short. This procedure was abandoned and the traction left *in situ*. The pharyngeal opening was closed with catgut sutures, and the rest of the wound packed with gauze.

Unfortunately the pharyngeal opening was not properly closed, the sutures cutting out almost immediately after recovery from the anesthetic. There was no shock to the operation, and the patient sat up in bed next day. The convalescence was uneventful, save for discomfort caused by saliva constantly exuding from the pharyngeal opening. On this account it was necessary to give esophageal feeding for two weeks. At the end of this time, the patient could eat soft solids comfortably. No dysphagia and no dyspnea. The wound was healed in three weeks, except for a small sinus. At the time of the operation, the patient was three months pregnant, and on May 7, 1903, gave birth to a baby girl weighing 7½ pounds. Delivery and convalescence were normal.

She has been well since the operation, has no dysphagia and speaks distinctly with a whispered voice. The silver canula requires occasional changing. It is now fourteen months since the operation, and there is no sign of recurrence.

COLLEGE CREDIT FOR MEDICAL STUDY.

The method of combining a course for the bachelor's degree in a literary and scientific college with part of the course in a professional school, which plan was described by Dr. George W. Hall in a communication in THE JOURNAL, March 5, is of especial interest and significance at the present time. This plan, proposed by President Kane of Wabash College and recently put into operation at that institution, is briefly described in the announcement for that school as follows: "A four years' course of study in which three years shall be prescribed work, all electives being reserved for the fourth year. Students taking this option will be permitted, if they so desire, to pursue their fourth year in attendance at a professional or technical school approved by the trustees of the college; retaining in the meantime their college standing and responsibility and being eligible for graduation with their class on the presentation of proper credits earned in this way. This option, it will be noted, affords the student an opportunity to secure during his fourth year such credits as will be recognized in full in both college and professional school, thus shortening by one year the aggregate time for academic and professional study."

It will be observed that the professional school selected must be approved by the trustees of the college. It is further intended that each student taking such a course shall be under the direct supervision of a member of the faculty of Wabash College, who will keep in constant touch with him and make sure that his year of work in the professional school is of such quality as to be the entire equivalent in culture value of the regular work of the senior year. It will doubtless be insisted on that the medical school chosen shall provide instruction in the fundamental medical branches of a comprehensive, thorough and scientific character.

There is a widespread and growing feeling in the medical profession, and especially among those engaged in medical education, that under the conditions now obtaining the best four years' high-school education affords an inadequate preparation for the study of medicine. On the other hand, it is clearly impracticable to require of all students the completion of the next stage in our educational scheme, namely, the possession of a bachelor's degree; indeed, it is believed by many that it would be a disadvantage to some students to spend so much time in preparatory work. In the effort to devise a satisfactory compromise between these extremes, several of the larger institutions have arranged a combined course, which has been described as the telescoping of the professional course into that of the collegiate course proper. It is possible at the present time for a student to procure the bachelor's degree, together with the degree in medicine, in six years in several institutions, among them the University of Chicago, the University of Michigan, the University of California, and Cornell University. As the course of collegiate study at these institutions was already elective, this combination has been effected without doing any serious violence to their existing regulations in reference to the bachelor's degree, it being understood, of course, that the branches which constitute the first two years of the medical curriculum are to be taught on strictly university lines by persons who are giving their whole time to teaching and research. The existence of such a plan in these larger institutions, however, places the smaller colleges at a distinct disadvantage. The temptation to students to leave them at the end of the sophomore year to enter an institution where they can complete the combined course in four remaining years, while if they were to complete the course in a smaller college it would require at least five, and in many cases six years, presents a real difficulty which the smaller college must meet in some way. It is no wonder, therefore, that some of these institutions have determined to meet this competition by providing instruction in the first two years of the medical curriculum. This fact that the example of the larger and well-equipped universities is being followed by the smaller colleges, for whom it can hardly be possible to give adequate instruction along medical lines, constitutes one of the chief objections which have been urged against the combined plan. The question for the small college is practically an economic one: To offer adequate instruction in human anatomy, physiology with laboratory work, pathology, and the various other branches usually taught in the first two years of the medical college, would be enormously expensive, when these departments must be maintained for from one or two to ten students each year. Even if an institution had abundant funds, it would be a questionable extravagance to provide instruction in these branches for so few students when the provision already made for such instruction in larger institutions is more than adequate to meet all demands. There can be little doubt that in many cases the instruction in human anatomy would be provided for by engaging the services of a local physician to give a perfunctory course in dissection in his leisure moments, and that the course in physiology and the other branches would be given, not by a physiologist, but by the professor of chemistry, physics, biology or some other branches who would have the classes in physiology added to his already abundant assignment of students.

To the smaller colleges seeking a plan to meet the demands of its students intending to study medicine and to meet the competition of the larger universities, the scheme proposed by President Kane offers an especially satisfactory and adequate solution. In one sense it may be spoken of as a compromise, for, while the student by leaving the college at the end of his sophomore year might in some cases complete the combined course in six years, he will be able, under the plan of President Kane, to complete it in seven years, and with a larger and more thorough preparation for his professional career. The plan will bring together the colleges and professional schools in a kind of pedagogic co-operation that will be of advantage to both. Of the numerous schemes which have been proposed to meet the demands of the time for a thorough preparation for medicine, this plan of Wabash College seems to us the most sane, reasonable and satisfactory which has yet been offered for those students who begin this work in the small college.

MOTOR PHENOMENA OF MANIA AND MELANCHOLIA.

Of the nature of the processes that underlie mental activity definite knowledge is wanting, but analogy would seem to permit the conclusion that they are comparable to the physiologic processes that take place in other organs than the brain. Like the activities peculiar to other organs, also those peculiar to the brain may be variously modified, and the resulting aberrations of function constitute the morbid processes grouped together under the general term insanity. Accordingly, in the one instance, as in the other, it is sometimes difficult to note exactly where the normal passes into the abnormal. Dr. W. H. B. Stoddart[1] records some interesting observations on the symptomatology of two forms of mental disease, namely, mania and melancholia, and he advances some ingenious speculations as to their cytology. He has called attention to the fact that melancholiacs suffer from rigidity of the muscles of the spinal column and of the large proximal joints, the movements of the wrists, fingers, ankles and toes being comparatively unimpaired. These phenomena are well defined only in severe cases, and but slight in mild cases. The rigidity is most marked in the muscles of the trunk and neck, and less marked successively at the shoulders and the hips, the elbows and the wrists; it is less marked also at the knees than at the hips, is slight at the ankles and is usually absent at the toes. The flexors are affected in more marked degree than the extensors, and the adductors in greater degree than the abductors. The attitude of the melancholiac is, therefore, one of general flexion and adduction, the shoulders being raised, owing to rigid contraction of the upper part of the trapezius. If with the melancholia there be associated some degree of restlessness or agitation, this shows itself most in the movements that are least interfered with, namely, those of the wrists and fingers, the ankles and toes.

In cases of mania, on the other hand, the movements during a state of motor excitement take place for the most part at the large proximal joints, according to his observation. In running, there is exaggerated movement at the hips; in waving the arms, the greatest movement takes place at the shoulders. The maniac shakes hands from the shoulder; the melancholiac from the wrist. The attitude of prayer is in the maniac with the hands upraised to heaven; in the melancholic with the hands clasped in front of the sternum. The typical attitude of the melancholiac is with the elbows close to the sides; that of the maniac with the elbows away from the sides. In some rare and severe cases of acute mania, however, the movements are peripheral as well as proximal, although those of the latter variety predominate.

Hughlings Jackson has put forward the hypothesis that the slow, proximal movements of the large joints are represented in the cortical motor areas in large cells, and the rapid, peripheral movements of the small joints in small nerve-cells. It is reasoned that if an irritating, stimulating product were formed within the cortical nerve-cells, there would be increased activity of the proximal movements because the large cells, having a smaller relative surface, are less well able to get rid of the deleterious substance. This condition, it is believed, occurs in mania. If, on the other hand, a depressing, paralyzing product were produced within the cortical nerve-cells, there would be weakness or paralysis of the proximal movements for a similar reason. Such a state of affairs is supposed to exist in melancholia, especially in the more stuporous forms. The same argument is applicable if the depressing influence within the nerve-cell be deficiency of nutrient matter (trophoplasm). The large cells suffer most because, having a smaller relative surface, they are less well able to absorb nutrient matter from the surrounding plasma. If the plasma contained an irritating, stimulating body, there would be greater activity of peripheral movements, because the small cortical nerve-cells have a larger relative surface exposed to the deleterious influence. These relations are encountered in cases of agitated melancholia, and occasionally also in cases of mania. Finally, if the plasma contained a paralyzing body or its equivalent—deficiency of normal nutritive and stimulating bodies—the paralysis would be more marked in the peripheral movements. These conditions are rarely present in cases of insanity, except as a result of coarse disease of the brain.

Dr. Stoddart also enters on some interesting reflections on the delusions of the two diseases under consideration. Not realizing that he is paralyzed, and finding himself unable to do the things that formerly he was able to do with ease, the patient may conclude that he is merely ill, or that his soul is lost, or that he is deserted by God, is eternally damned. or that he has committed the unpardonable sin. In this frame of mind he may fix on some trivial act as the cause of all of his trouble, or by a process of simple paramnesia he may even falsely accuse himself. Some patients thus come to think themselves dead, while others believe themselves altered in some way. In hypochondriacal melancholiacs the weakness, although general, appears to attract the patient's notice locally. Thus he may develop the delusion that he can not walk or stand up, or that his legs are brittle and hence made of glass. As a result of various sensations, the patient may gain the idea that his breath is gone or that his throat or bowels are permanently locked up. If the patient normally be suspicious, or if he suffer from hallucinations or illusions, delusions of persecution may develop.

---

[1] Lancet, March 5, 1904, p. 639.

In the maniac the delusions of exaltation arise in a corresponding manner from the feeling of activity that results from the stimulation of the cortical nerve-cells. The patient feels strong and capable of the most wonderful athletic feats. Hence arises the general idea of power and the development of delusions of being a duke, a lord, a king, God, or of the possession of untold wealth. The development of these delusions is, however, often modified by the occurrence of hallucinations, and then the feeling of activity is thrown into the background by perversions of the senses.

The foregoing views are interesting and ingenious, and they possess certain hypothetical value. While not susceptible of proof, they can not in the nature of things be successfully contradicted, so that, for the present at least, they may receive tentative acceptance. Function is, no doubt, merely an expression of cell-activity, and disease-symptoms are to be explained by abnormal cell action. The means of demonstration are, however. not yet available.

WHY IS THE ABILITY OF MOTHERS TO NURSE THEIR CHILDREN DISAPPEARING?

That the ability of women to nurse their children is diminishing with great rapidity is a fact noted by all physicians, although it may be attributed to various causes. Professor Bunge of Basel has recently published[1] the results of his study into the causes underlying the loss of this important function, a loss which, he states, affects more than half of the women living in the cities of central Europe. He has collected statistics from physicians, chiefly in Germany, concerning the following points: Number of children borne by the woman; number of children she was able to nurse for nine months each—if unable to nurse, why; number of children borne by her mother; how many her mother could nurse; alcoholism in father and mother. Answers were received covering 1,629 cases, sufficient to enable Bunge to draw conclusions with safety. The women who could nurse their children without having to supplement the breast milk with other alimentation, for a period of nine months—this being the customary period in Germany—he denominates for brevity's sake "capables." The "incapables" are those who were unable to nurse any or some of their children, or who could nurse them for an insufficient length of time, or whose milk was of insufficient nutritional value. When the nursing was interrupted by a passing illness—by mastitis or a subsequent pregnancy—the case was still counted as a "capable." He did not include in the study those cases which were prevented from nursing by malformation of the nipple.

The "capables" were found to number 519, the "incapables" 1,110. Among these 519 there were 423 who could give information as to their own mothers in this respect, and with one single exception the mothers of these had also been able to nurse all their children for the normal length of time. But when inquiry was made as to the history of the mothers of the "incapables," it was found that 39.2 per cent. had been able to perform this function normally. Thus it is clearly shown that *almost without exception* the daughter of a mother who can not nurse her children is likewise unable to do so; and not only this, but there is an increase in the number of women unable to nurse which can not be explained by hereditary influences on the mother's side. Bunge then studied the paternal history of those "incapables" whose mothers had been "capables," and found that chronic alcoholism was present in 78 per cent. of the fathers of these women. As chronic alcoholics he classes those who drink daily more than two liters of beer or one liter of wine, and those who are notorious drunkards; 42 per cent. belonged to this last class. On the other hand, only 2.6 per cent. of the "capable" daughters of "capable" mothers had had drunkards for fathers. Examination of the histories of families of drunkards who had had several daughters showed that in many cases the younger daughters were incapable of nursing, while the older daughters were wholly or partially capable—the father having gradually undermined his health until he was at last unable to beget an entirely normal child. A further study of the family history of this same class of women revealed a connection between this loss of function and a susceptibility to nervous and psychical disturbances, for while only 1.6 per cent. of the class of "capables" were found to suffer from disorders of the nervous system, the enormous proportion of 25.9 per cent. was reached for the "incapable" daughters of "incapable" mothers.

The nursing function, therefore, seems destined to gradually disappear even without any increase of alcoholism among men. For, if it is true, as Bunge's statistics show, that this function once lost is almost never regained, then the number of these "incapables" must be larger in each generation, for there will always be alcoholic fathers to beget "incapable" daughters from "capable" mothers.

THE ETIOLOGY AND PATHOGENESIS OF TYPHOID FEVER.

There is probably no important disease regarding which our conceptions have had to be changed more frequently than typhoid fever. Originally classed with typhus, it was first satisfactorily separated from that disease by Louis and his pupils, and particularly by Gerhard in this country. No great change in our conception of the disease took place from this time until the discovery of the typhoid bacillus by Eberth in 1880. From that time almost to the present the etiology of the disease has been considered as settled, but postmortem bacteriology has led us considerably to change our views as to the pathologic anatomy of the disease. The old idea of a fixed pathologic picture with intestinal ulcerations as the predominating feature has been revised, and we now know that although this picture is the usual one, the pathologic appearances, like the clinical picture, may be varied. Within the last few years infections with closely allied germs, which have been classed as paratyphoid or paracolon bacilli, have been reported from time to time, and the question of importance at the present is the relation of these closely allied infections to one another.

In a recent paper Juergens,[1] who has had a wide personal experience with typhoid fever and with paratyphoid infection, discusses the relationship between the two at length. He points out that most of the writers who have described paratyphoid infections have endeavored to demonstrate that these cases can be distinguished from true typhoid fever by the clinical course of the infection, the pathologic findings, and the use of the serum reaction. Juergens' paper is an analysis of the reported cases of paratyphoid infection, having in view the proving or disproving of these assertions.

Concerning the clinical picture, Juergens concludes that it is impossible to differentiate typhoid from paratyphoid infections. Both infections may show varied clinical pictures. In some cases of paratyphoid infection every feature of typical typhoid is duplicated, and, on the other hand, cases of paratyphoid infection running a septicemic course can be paralleled by the now well-recognized cases of typhoid septicemia. Not only the disease itself, but also the complications and sequelæ, are the same in the two infections; venous thrombosis, pneumonia, cystitis, hemorrhage from the bowels and even relapses have been seen in paratyphoid cases. The statement that the paratyphoid infections usually run a milder course, which is made by most writers on the subject, Juergens does not consider to be upheld by the available facts. As he points out, only one or two extensive outbreaks of paratyphoid infection have been reported, and outside of these only scattered case reports are to be found. It is true that the paratyphoid outbreaks so far reported have been mild, but some reported epidemics of typhoid are equally mild, and the number of single cases is too small to enable a reliable judgment as to this point to be formed. The postmortems on paratyphoid cases have been very few in number, but none of them shows findings which are incompatible with infection with the typhoid bacillus.

In considering the serum reaction, Juergens claims that a diagnosis based on this alone is entirely unjustifiable in the light of our present knowledge of group reactions. He points out that the serum of many paratyphoid cases gives a well-marked reaction with the typhoid bacillus or the colon bacillus, and while there may be a quantitative difference in the dilutions necessary to produce the reaction with these different organisms, this does not suffice to differentiate the different infections, recent research having shown that specific reactions can not be differentiated from group reactions by quantitative measures alone.

Juergens' conclusions can be readily gathered from the preceding remarks, and it must be added that as a result of these conclusions he discards many of the reported cases of paratyphoid infection as being based on insufficient or unreliable data. He requires for a positive diagnosis of paratyphoid infection the isolation of the paratyphoid bacillus from the blood or excreta if possible, and failing this not only the serum reaction, but also the Pfeiffer test on animals. Juergens deprecates the prevalent grouping of typhoid and paratyphoid infections as separate diseases.

THE INHERITANCE OF THE DISPOSITION TO TUBERCULOSIS.

Since the beginning of the bacteriologic era our views as to the inheritance of tuberculosis have undergone several changes. When the tubercle bacillus was first discovered it looked as though the matter was greatly simplified and would soon be cleared up. At first it was thought that the tubercle bacillus itself was handed down from generation to generation, but pathologic experience soon disproved this, and even at the present day the reported cases of true inheritance of the germ can almost be counted on the fingers. The appreciation that the bacilli themselves were but rarely transmitted led to the formulation of the theory of the transmission of the soil, as the French have called it. It was taken for granted that some structural peculiarity was transmitted which favored the multiplication of the tubercle bacillus in the tissues of the unfortunate individuals who possessed it. This view is, in fact, the prevailing view at the present time, though of late years certain observers have been placing more and more stress on the importance of contact with infected cases, and still others have recently brought out facts pointing to the possibility of latent inherited tuberculosis.

In a recent article, Burckhardt[1] has recorded the results of his comparison of two hundred and fifty tuberculous and two hundred and fifty non-tuberculous individuals, as regards their family history. In a brief review of recent articles bearing on the subject, he points out that the work of Kuthy, who found no difference between the family histories of tuberculous and non-tuberculous subjects, is not reliable on account of the fact that this observer did not compare equal numbers of the two classes of cases. In his study, Burckhardt considered only relatives closely related to his cases. He collected the histories of the grandparents, the parents and their brothers and sisters, the brothers and sisters of the patient, and, if married, the husband or wife and the children. According to Burckhardt, this would mean on the average the consideration of fifteen relatives. His results at first glance seem to be decidedly in favor of inheritance of the disposition, as he found that there was a family history of tuberculosis in 66 per cent. of the tuberculous cases, and in only 42 per cent. of the non-tuberculous.

---

[1] Zeitschrift f. klin. Med., vol. xxv, Nos. 1-2.

[1] Zeitschrift für Tuberculose, vol. v, No. 4.

Further analysis shows, however, that the results when closely scrutinized suggest a different interpretation. Burckhardt found, for example, that if we consider the percentage of tuberculosis in the brothers and sisters of patients, or in the mother, there seems to be strong evidence in favor of hereditary transmission. Thus in his two hundred and fifty tuberculous cases, 38 per cent. had one or more brothers or sisters with the disease, while of the two hundred and fifty non-tuberculous, only 18 per cent. had brothers or sisters with the disease. In the tuberculous cases there was a history of tuberculous disease in the mother in 15.2 per cent., while such a history was present in only 6.8 per cent. of the non-tuberculous cases. When the history as regards the father was considered, however, it was found that tuberculous and non-tuberculous individuals showed an almost equal percentage of infection, the tuberculous having 14.4 per cent. of tuberculous fathers, and the non-tuberculous 11.6 per cent. As Burckhardt points out, these facts may be interpreted to mean that transmission takes place by contact with infected cases, this explanation being just as logical as the assumption of heredity of the soil, as the members of a family are much more likely to be brought into contact with their mother or their sisters and brothers than with their father, who is away from home at his work. While Burckhardt seems to favor the importance of direct transmission by contact, he does not believe that it can be stated at present that heredity is of no importance.

The question as to just what its importance is must be solved by further studies, and the line of investigation suggested is that outlined by Schrötter, viz., the investigation of the descendants of tuberculous individuals from the anatomic, physiologic and serologic standpoints. The questions are still far from being satisfactorily solved; in fact, new investigation often seems only to open up new problems and to indicate unsuspected possibilities.

THE PROTOZOA IN DISEASE.

The *Century Magazine* for April contains two articles that are in different ways of medical interest. In the first Prof. Gary N. Calkins of Columbia University furnishes a very readable account of the protozoa in disease and gives in an intelligible manner the general facts in regard to the development of these disease-producers with which we are specially concerned. The article is illustrated by original drawings from the author's own pen and may be considered as authoritative, though appearing in a popular magazine. He assumes perhaps a little too much in admitting—as it appears to us that he does—that the protozoan origin of scarlet and yellow fevers has been discovered, but that does not detract from the general value of his article. Furnishing as it does in a brief but very comprehensible way the main biologic facts in regard to pathologic sporozoa which are probably not known to the great majority of physicians, the article is well worth reading by medical men.

WEIR MITCHELL ON GEORGE WASHINGTON.

The other contribution in the *Century,* referred to above, is by Dr. Weir Mitchell, whose literary achievements have widened his reputation so well earned by his work in medicine. It is in a measure a sort of historical novel, as it is in the form of an assumed autobiography of George Washington. We do not see that Dr. Mitchell has attempted to cultivate or imitate Washington's style as we know it from his state papers and addresses. We doubt whether Washington could have expressed himself anywhere nearly as well as Dr. Mitchell does it for him. Still he might have very naturally thought out the same thoughts and the paper shows a very close study of the early and family history of the father of his country. Medical men will find of interest this latest contribution of a colleague who has reflected honor on the profession in more ways than one.

EXPERT WITNESSES APPOINTED BY THE COURT.

The method of appointing expert witnesses has been so much discussed pro and con in every way that court decisions which throw any light on it are welcome. In a recent case in Kentucky[1] the appellant pleaded as an error that the two medical witnesses who testified in the case regarding the extent of the plaintiff's injuries were appointed by the court, and that the attorney for the other side had been allowed to make this fact known to the jury. The Court of Appeals decided that the physicians had been appointed by the court under the large discretion which it possessed. The question was not a matter as to how they came to know the facts, but as to the truth of their testimony, and the knowledge on the part of the jury that the witnesses came from the impartial appointment of the judge could not prejudice the case against the plaintiff. It would appear from this that a precedent has been fairly set in that state for the appointment of expert witnesses in damage cases by the court, and for the doing away with partisan experts, about which jurists have said so much in discussion and criticism. Medical expert testimony is no worse than any other expert testimony, but it suffers by the fact that the courts usually recognize any *soi-disant* expert as perfectly competent to act in that capacity and the juries are not supposed to be discriminating as to the quality of those who thus represent themselves. If the courts can make an intelligent appointment of medical experts the difficulty will be largely overcome. It remains to be shown that the judges know who are and who are not experts.

MARKED SOMNOLENCE OF LONG STANDING AS A SYMPTOM OF SYPHILIS.

Sleep is a condition of diminished irritability of the entire nervous system, during which opportunity is afforded for recuperation from antecedent fatigue. The exact factors on which sleep depends are not definitely known, although it may be surmised that they are in part chemical or metabolic and in part circulatory or vascular. The amount of sleep required varies in different individuals, and in the same individual at different times. Deficient sleep or insomnia is observed in association with a number of disorders of the nervous system, directly or indirectly; abnormal somnolence more rarely under analogous conditions. A most extraordinary instance of prolonged somnolence, probably of hysterical origin, has recently been placed on record,[1] the patient, a woman, having slept, as recorded, for seventeen years. Somnolence further occurs occasionally as a symptom of syphilitic disease of the cerebral blood vessels, and an unusual case of this character is reported by Mr. William B. Bennett.[2] The patient was a man, thirty-four years old, with a history of the initial lesion of syphilis eight years previously, who presented aphasia, had several convulsions and exhibited marked somnolence, both by day and by night, covering a period of five months. Headache and hemiplegia were conspicuously absent. Complete recovery followed active treatment with mercury and iodin. The lesions are believed to have consisted in extensive syphilitic inflammation of the cerebral arteries, without thrombosis or embolism, but possibly with spasm of the arteries.

THE PROPHYLAXIS OF MALARIA.

Physicians know how difficult it is to persuade the public to adopt preventive measures in preventable diseases. It generally needs an extensive outbreak and considerable loss of life to impress on the mind of the average citizen the necessity for prophylactic measures. If this is true of diseases which have a considerable mortality, it is easy to see why, in a disease like malaria, which seldom results fatally in our climate, so few systematic attempts at stamping out the disease have been made. And yet the comparatively small amount of experience collected in the last few years tends to show that a district can be almost entirely rid of this disease in a relatively short time and at a relatively small expense. Two methods are at our disposal—that suggested by Koch, which consists in combating the disease in the human being, and the method mostly used by the French and English speaking peoples, which consists of destroying the intermediate host—the mosquito—and in protecting human beings against its bites. Two recent papers by French authors[1] give some idea of the relative effectiveness of the two systems. It would seem that the method usually employed in this country is much more effective than Koch's method. The two main reasons why Koch's method is difficult to enforce are the difficulty of getting people to take quinin when they think they are well, and the impossibility of detecting larvate cases of the disease even with the aid of a blood examination. A small amount of work has been done in this country attempting to exterminate malaria, but the main malarious districts as yet remain almost untouched. It is to be hoped that in the near future the work will be taken up in a systematic way.

THE MARAGLIANO LECTURE.

The results of the studies of Professor Maragliano, which have been fully reported from time to time in The Journal,[2] are very fully summarized in the latest Phipps lecture,[3] which was to have been delivered March 28. Its statements in detail will be of interest to American readers, though the facts and views there expressed have been already given in foreign journals. Behring's experiments with vaccination on calves against tuberculosis are well known, but Professor Maragliano has gone further, and he reports the results of attempts to immunize human beings by the use of vaccine material containing no living bacteria. Of course, the test of such immunity against cultures of living bacteria can not be made in our species. Behring's results in calves do not warrant the application of his method to the human subject, and Maragliano is evidently not the man to engage in dangerous experiments. Still further, he finds that the protective elements of the serum are capable of being absorbed through the mucosa of the digestive tract, and that by ingestion a certain degree of immunity can be acquired. This fact seems to be one of practical importance, as he says why "instead of ordinary milk should we not use the milk of immune animals," and thus produce a passive immunity which experimental results have already warranted us to expect. Such experiments can certainly be tried, and it only requires the general practice of immunization of our domestic animals to ensure its practicability, and it is to be hoped also its success. While many of us will accept Professor Maragliano's statements with some reserve, considering him perhaps as showing the enthusiasm of the discoverer and exceeding the assured limit of actual results in his views, nevertheless there is much in his lecture that deserves our careful consideration, and its publication in our language can hardly fail to have a useful influence. His desire that the experiments with feeding with immunized milk and meat should be tested on a broader scale in this country, where, as he believes, the facilities for such are so much greater than abroad, will, we hope, be gratified, at least to a certain extent.

A SIMPLE BLOOD TEST FOR TYPHOID.

In a recent number of The Journal we noticed editorially Ficker's test for typhoid with a solution of dead bacilli. It was also stated that the preparation and instruments were put up by Merck of Darmstadt for ready use. In the last number of the *Journal of Infectious Diseases*, Ruediger reports the results with typhoid culture bouillon, in which the bacillus had been killed by formalin 1 c.c. to 100 c.c. of bouillon, and the method seems to be fully as simple and practical as that devised by Ficker. It is, therefore, in the power of any one who can make cultures from typhoid bacilli to provide his own solution, and Ruediger's paper shows the peculiar sensitiveness of these dead cultures and mentions in a footnote that a good reaction was obtained with cultures that had been killed just one year before. The process is a very simple one: Add four drops of blood to 2 c.c. of a 1 to 500 solution of formalin in distilled water. When laking is complete, add 4 c.c. of the dead culture to 1 c.c. of the blood solution and set the two aside. If agglutination takes place the dead organisms collect in clumps, and within an hour or two are seen as a flocculent precipitate settling toward the bottom, leaving the bouillon clear at the end of twelve to twenty-four hours. Dried blood can be employed as well as fresh blood, and the only special precaution in the test is to shake the culture before using it to stir up the organisms from the bottom where they are likely to settle. One or two test tubes and a microscope are all that are necessary. The method seems to be even simpler than the Ficker one, which Ruediger does not mention, and is within the reach of every practical clinician.

Medical News.

ALABAMA.

Smallpox.—Huntsville reports 29 cases in its pesthouse, with no recent deaths. The disease is believed to be under control. ——The disease is reported epidemic in Marshall County, north of the Tennessee River.

Commencement.—At the tenth annual commencement exercises of Birmingham Medical College, April 2, Capt. Richmond Pearson Hobson, late U. S. Navy, delivered the address of the evening, and Dr. Benjamin L. Wyman conferred the degrees.

Seeks Mandamus.—The Mobile Medical College has applied for a mandamus to compel the state auditor and state treasurer to pay the first installment of $5,000 on the $20,000 appropriated by a bill passed by the last legislature, but which was not signed by the governor.

Graduating Exercises.—The closing exercises of the thirty-eighth annual session of the Medical College of Alabama, Mobile, were held March 31. Forty-four diplomas were issued. The president of the university conferred the degrees. The attendance during the session was the largest in the history of the college. The recent enlargement of its laboratories and equipment for pathologic and chemical studies are in line with the policy of the institution.

CALIFORNIA.

Inspection of School Children.—On April 1, inspection of the health conditions among San Francisco school children was inaugurated by a corps of volunteer medical inspectors.

February Mortality.—The deaths for February numbered 1496, equivalent to an annual mortality of 17.04 per 1,000. Tuberculosis caused 247 deaths; heart disease, 184; pneumonia, 169; cancer, 72; and bubonic plague, 5.

Society Endorses Medical Efficiency Bill.—The Santa Barbara County Medical Society, on March 15, adopted resolutions favoring the bill to increase the efficiency of the medical department, U. S. Army, and urging that the provisions disqualifying officers of the medical reserve corps from retirement, retirement pay and pensions, be stricken out.

New Cottage at Agnews.—The trustees of Agnews State Asylum have adopted the plans for the proposed new cottage for the treatment of the insane at that place. The cottage is to cost $37,965, and will accommodate 100 patients.

Personal.—Dr. John R. Colburn, Los Angeles, has been made chief surgeon of the San Pedro, Los Angeles and Salt Lake Railroad, vice Dr. Charles F. Taggart, resigned.——Dr. William M. Lawlor has been made receiving clerk at the San Francisco City and County Hospital.——Dr. George F. Reinhardt has succeeded Dr. Frank H. Payne as health officer of Berkeley.

ILLINOIS.

Monmouth Hospital Open.—The new Monmouth Hospital opened for the reception of patients, April 1.

Diseases Close Schools.—Smallpox has caused the closure of the public schools of Marseilles.——Philo, Emden and Divernon schools are closed on account of scarlet fever.

Surgeon Resigns.—Dr. George N. Kreider, Springfield, major and surgeon, assigned to the Fifth Infantry, I. N. G., has resigned.——Dr. Arthur F. Wilhelmy, Decatur, has been designated to fill the vacancy on the examining board of the regiment, caused by Dr. Kreider's resignation.

How the Government Deals with Fraud.—"Dr." J. F. Braun, Mascoutah, who has been conducting a so-called "health home," and who advertised to cure many ills without medicine, and by absent treatment, has been sentenced to six months' imprisonment and to pay a fine of $500 and costs by the United States Court at Cairo for using the mails for fraudulent purposes. The State Board of Health has instituted several suits against Braun during the past year, but was able to obtain a conviction in only one instance. It was found necessary, therefore, to obtain the aid of the federal authorities.

Chicago.

Smallpox.—There are at present 11 cases of smallpox in Chicago, six of which are in one Dowieite family, which refused vaccination.

Off for Europe.—Dr. G. Paull Marquis, lieutenant colonel and assistant surgeon general, sails April 9, with his family, for a stay of seven months in Vienna.——Dr. Ludvig Hektoen sailed for Liverpool on the *Etruria*, April 2.

Antitoxin Stations.—Diphtheria antitoxin stations have been established in 36 localities throughout the city. At these stations physicians may obtain antitoxin free for indigent patients, and at low rates for those able to pay. Culture outfits may also be obtained at these stations.

Decrease in Air-Borne Diseases.—During the first quarter of 1904 30 per cent. fewer children between one and five years of age died than in 1903. The almost continuous snow blanket reduced the prevalence of the air-borne diseases of childhood, so that there were 21 per cent. fewer deaths from diphtheria and 42 per cent. fewer from scarlet fever, while there were but 3 deaths from measles and 4 from whooping cough this year as against 69 and 116 respectively last year.

Deaths of Quarter, Month and Week.—The deaths for the quarter were 7,675, a decrease of 181 from those of 1903, and equivalent to an annual death rate of 15.77 per 1,000. Of these, 1811, or nearly 23.6 per cent., were due to pneumonia, an increase of 170 over the preceding year. Consumption caused 858 deaths; heart disease, 582; Bright's disease, 478, and violence, 441.——During March the deaths numbered 2,609, a decrease of 104, as compared with March, 1903, and equivalent to an annual rate of 15.74 per 1,000. Pneumonia was, as usual, in the lead, causing 621 deaths, or 23.76 per cent. Consumption caused 332 deaths; heart disease, 181; Bright's disease, 157, and violence, 156.——During the week ended April 2, 576 deaths occurred, equivalent to a yearly mortality of 15.40 per 1,000. The percentage of deaths from pneumonia was 21.53 The deaths from pneumonia were 124; from consumption, 80; from heart disease and Bright's disease, each 36, and from violence, 33.

KANSAS.

Personal.—Dr. J. F. McNaughton, assistant physician at the Topeka State Hospital, has resigned and will practice in Gove City.

Asks Exemption from Taxation.—Dr. Henry H. Keith, Topeka, has petitioned the board of commissioners of Shawnee County to exempt his private hospital from taxation, on the ground that he does $100 worth of charity work each month, and that he does not receive state aid.

Commencement.—The tenth annual commencement of the College of Physicians and Surgeons was held in Kansas City, March 31. A class of 11 was graduated; the annual address was delivered by Lowell L. McAfee, LL.D., and the degrees were conferred by Hon. W. H. Brown, assisted by Dr. Ellery M. Hetherington, secretary of the faculty.

Second Munificent Gift.—Dr. Simeon Bell, Rosedale, has given the University of Kansas 440 acres of land in Jackson and Cass counties, Missouri, stipulating that if $25,000 is not realized from the sale of the land the difference will be made up in cash. This is Dr. Bell's second gift to the university, and is for the maintenance of a hospital to be established in Rosedale as a memorial to Dr. Bell's deceased wife.

KENTUCKY.

Smallpox Epidemic.—The secretary of the State Board of Health reports serious outbreaks of smallpox at Earlington, Springfield and Burlington.

Reynolds Wins Suit.—Dr. Dudley S. Reynolds, Louisville, has been given judgment for $7,750 against the Louisville and Nashville Railroad for damage sustained by him which caused pain and loss of practice for a time.

Medical Knowledge for the Masses.—The Lexington Medical Society has appointed a press committee to instruct the public through the medium of the press in the laws of hygiene and sanitation. This committee has instructions to prepare papers along practical lines, to be read before the society, which if approved will be given to the lay press for publication.

Personal.—Dr. James C. Carrick has been elected president of the board of health, and Dr. Nathan R. Simmons, health officer of Lexington.——Dr. Addison S. Robertson has succeeded Dr. Charles R. Garr, as health officer of Flemingsburg.——Dr. Heman Humphrey, Louisville, has been selected as interne in the City Hospital.——Dr. James M. Grant, Petersburg, has been made chairman of the Boone County Board of Health.

Commencements.—Louisville Medical College held its commencement exercises, March 26, graduating a class of 61. Dr. W. F. Sheridan delivered the address of the evening.——Diplomas were awarded to 36 at the annual commencement of the medical department of the University of Louisville, March 31. Dr. James M. Bodine presented the class to Hon. T. L. Burnett, who conferred the degrees. Dr. Henry A. Cottell delivered the faculty address.

MARYLAND.

Baltimore Personal.—Dr. C. Wilbur Larbin of the City Hospital staff has gone to Harrisburg, Pa., to engage in practice.

Half a Million to Hospital.—John D. Rockefeller has given $500,000 to Johns Hopkins Hospital as an addition to the endowment fund to replace the loss suffered in the great fire in Baltimore. The gift has been accepted by the trustees of the institution.

Baltimore Deaths.—There were 202 deaths last week, an annual rate of 18.45 per 1,000. Consumption and pneumonia each caused 31 deaths; grip caused 9 and bronchitis 6. Bright's disease came next to pneumonia and consumption with 16 deaths. The gradual increase in Bright's disease is noticeable.

Mumps Germ Said To Be Found.—It is said that Dr. S. Darling, resident pathologist at the City Hospital, Baltimore, working in Prof. William Royal Stokes' laboratory, has probably discovered the germ of mumps. It is a diplococcus, similar to one described by Laveran and Catrin in 1893, but not connected by them with mumps. The organism was obtained from an autopsy on a child who died from the uncomplicated disease It was obtained in pure culture on blood serum.

The Omnibus Bill Amended.—In the passage of the omnibus appropriation bill (the medical items of which were given in The Journal last week), through the house of delegates, amendments were adopted granting $4,000 annually to each of the following institutions: University of Maryland; College of Physicians and Surgeons; Baltimore Medical College, and Maryland Medical College. It also added to the appropriation of the Baltimore Eye, Ear and Throat Hospital, $10.000 for an additional building: $1,500 a year to the Woman's Medical College, and Good Samaritan Hospital: $1.200 per annum to the Emergency Hospital at Frederick, and gave $15,000 to Hospital for Consumptives.

Ehrlich to Give Herter Lectures.—The authorities of the Johns Hopkins University announce the subjects of the Herter course of lectures to be delivered by Prof. Paul Ehrlich, the director of the Royal Prussian Institute of Experimental Therapeutics at Frankfort-on-the-Main, April 12, 13 and 14. They are: (1) "The Mutual Relations Between Toxin and Antitoxin"; (2) "Physical Chemistry vs. Biology and the Doctrines of Immunity"; (3) "Cytotoxins and Cytotoxic Immunity." The lectures will be in German, but the audience will be furnished with English translations, so that the speaker can be followed more easily. The course of lectures will be open to the general public, as well as to physicians. The Herter course was founded in 1902 by Dr. and Mrs. Christian Herter of New York City, who donated $25,000 for the purpose. They are to be delivered annually by some eminent physiologist or pathologist.

MASSACHUSETTS.

Liberal Village Appropriation.—Brookline has appropriated $34,000 for the public health department and $9,500 to maintain its bath house for the coming year.

Boston's Contributions to Insane Hospitals.—During the past year Boston has sent 260 patients to the Hospital for the Chronic Insane on Long Island; 657 to the state hospitals at Tewksbury, 58 to the Observation Hospital, 134 to insane hospitals, and 31 to the State Hospital for Dipsomaniacs.

Hospital Music Fund.—The Hospital Music Fund will provide music for various hospitals and homes for children, cripples and invalids each Sunday till May 1. Their total contribution to such institutions during this season in Boston, Cambridge, Somerville, Brookline and Chelsea has been 52 concerts. Dr. John Dixwell is in charge.

Personal.—Dr. Ambrose J. Gallison of Franklin has been appointed assistant medical examiner of the sixth Norfolk district.——Dr. George L. Tobey, Clinton, has been elected chairman of the town board of health.——Dr. Charles F. Branch was elected chairman of the Amherst Board of Health.——Dr. Charles S. Holden, Attleboro, has been reappointed medical examiner for the Bristol district.

Disease and Death.—The total number of deaths reported to the Boston Board of Health for the six weeks ended April 2 was 1,420, an increase of 42 over the corresponding period of last year, and an average weekly increase of 20.45. There were 279 cases of diphtheria, with 27 deaths; 161 of scarlet fever, with 6 deaths; 45 of typhoid fever, with 11 deaths; 1,099 of measles, with 33 deaths, and 291 of tuberculosis, with 188 deaths. Pneumonia caused 254 deaths; whooping cough, 5; heart disease, 138; bronchitis, 42; and marasmus, 18. Of those reported 255 were under 1 year old, 381 under 5, and 303 over 60 years of age.

MICHIGAN.

Epidemic Typhoid in Escanaba.—Escanaba is now conservatively estimated to have 200 cases of typhoid fever, and a large number of cases of so-called "winter cholera."

Fire at Escanaba Hospital.—In a fire at the Delta County Hospital, Escanaba, more than sixty patients were driven out of the buildings by the flames into the snow, to neighboring houses, where they were cared for.

Gift for Care of Consumptives.—Miss Helen May Wells, Saginaw, has tendered to the trustees of Saginaw General Hospital, $30,000 to be used in the construction, equipment and maintenance of one or more cottages for the treatment of consumption, as a memorial to her father and mother.

Comparative Morbidity.—For February, 1904, compared with the preceding month, typhoid fever, measles, cancer and whooping cough were more prevalent, and pneumonia and remittent fever were less prevalent. For the same month, compared with the average for February in the last ten years, consumption, typhoid fever, measles, diphtheria and smallpox were more than usually prevalent; and pneumonia, erysipelas, intermittent fever, inflammation of bowels, remittent fever, whooping cough and cholera infantum were less than usually prevalent.

February Mortality of Michigan.—The total number of deaths reported during February was 3,389, an increase of 263 over the preceding month. The death rate rose from 14.7 per 1,000 in January to 17.1 in February. Important causes of death were as follows: Tuberculosis, 189; typhoid fever, 42; diphtheria and croup, 57; scarlet fever, 32; measles, 21; whooping cough, 27; pneumonia, 487; influenza, 195; cancer, 128; accidents and violence, 175. There were 3 deaths from smallpox, and one death from chickenpox was reported from Detroit.

Free Treatment for Deformed Children.—Announcement has been made that any child of Michigan birth born deformed is entitled to free treatment at the hospital in connection with the medical department of the University of Michigan, Ann Arbor, on the following conditions: 1. that the physician present at the child's birth will certify that he was so present, that the child was born deformed, and that in his judgment it can be helped by treatment; and 2, that the mayor of the city, the president of the village, or the supervisor of the township in which the child lives, will order the child cared for at the hospital.

The Most Dangerous Communicable Diseases.—Meningitis was reported present in Michigan during February at 10 places; whooping cough at 20 places; typhoid fever at 87 places; diphtheria at 97 places; pneumonia at 109 places; measles at 129 places; smallpox at 131 places; scarlet fever at 162 places; and consumption at 212 places. Meningitis was reported present at 2 places more; whooping cough at 2 places less; typhoid fever at 6 places less; diphtheria at 4 places less; pneumonia at 11 places more; measles at 27 places more; smallpox at 9 places more; scarlet fever at 33 places less; and consumption at 17 places more, in the month of February, 1904, than in the preceding month.

Warning to Cities and Villages Having a General Water Supply.—The bulletin issued by the State Board of Health for the month ended Feb. 27, 1904, indicates that typhoid fever was much more prevalent than the average for the corresponding month in the ten preceding years. Of the reports received more than twice the average proportion stated the presence of the disease. A contamination of the water supply would account for the unusual prevalence of this disease. In winter that does not usually occur in country districts, the contents of privies being frozen so they can not leach into wells. The unusual reports of typhoid fever came from cities having a general water supply. The inference is that these places are using water from a polluted reservoir, river, or lake, and it is earnestly suggested that the local authorities should promptly notify the citizens to boil the drinking water, so that the recent fatal experience at Butler, Pa., may not be duplicated in Michigan.

MISSOURI.

To Check Urban Tuberculosis.—The committee of 30 appointed at a recent meeting of the St. Louis Society for the Prevention of Tuberculosis met, March 25, and discussed plans for permanent organization. A subcommittee of five, of which Drs. William Porter, George M. Tuttle and Henry J. Scherk are the medical members, was appointed to draft plans for permanent organization.

May Not Prescribe and Also Dispense Whiskey.—In the case of Dr. Thomas S. Manning, Vandalia, who having been fined $100 for violating the drug dramshop law, appealed on the ground that he had the right as a physician to prescribe liquor, and as a druggist to fill his own prescription, the Court of Appeals has decided against the appeal, and sustained the decision of the lower court.

Graduate at St. Joseph.—Ensworth Medical College graduated a class of 19, March 29, Dr. Thomas H. Doyle, president, presenting the diplomas, the faculty address being delivered by Dr. John M. Bell, and the address on behalf of the citizens by W. B. Norris.——A class of 8 received diplomas at the commencement exercises of the Central Medical College, April 1. Dr. Albert L. Gray presided; Dr. O. Beverly Campbell delivered the faculty address, Samuel I. Motter the address on behalf of the citizens, and the president, Dr. Thompson E. Potter, conferred the degrees.

Malpractice Limitation.—At the meeting of the Kansas City Academy of Medicine, February 20, Dr. Lewis B. Sawyer read a paper on "Civil Malpractice Limitations." He commented on the absence of specific legislation on this subject, and explained that it was governed by the statutes controlling torts, which in a general way include damage suits of the character under consideration. This rather loose regulation allows complainants to bring suit any time within five years after the alleged injury or injustice has been inflicted. The essayist, who is also an attorney, believes that the ends of justice would be better served by a specific statutory limitation of one year.

NEW YORK.

Hospital Strife Ended.—Commissioner McAdoo has redistributed the ambulance territory of St. Mary's and Jamaica hospitals. This settles a dispute of long standing.

High Mortality.—The average number of deaths reported by the State Board of Health was about 440 daily during February, an average of 90 more per diem than during 1903.

March Deaths and Diseases.—The State Department of Health reports that there were 12,749 deaths in the state during March, an average of 440 a day. The total exceeds by 2,000 the average for March for five years. Pneumonia caused 1,820 deaths. Smallpox is reported in Cattaraugus, Chautauqua, Erie, and several other counties, but the disease is less active than a month ago.

Tenements and Tuberculosis.—The following committee has been appointed by the Buffalo Charity Organization on Tenements and Tuberculosis: Dr. Peter W. Van Peyma, Frank Carter, George W. Gillette, John D. Larkin, Jr., Dr. Ludwig Schroeter, and Giovanni Banchetti. Dr. John H. Pryor is advisor to the committee. Dr. William C. Callahan has been appointed to procure material on which the committee can act.

New Bills.—Assemblyman McMannis has introduced a bill authorizing the appropriation of $20,000 for the New York Eye and Ear Infirmary.——Assemblyman DeGroot has introduced a bill asking for the appointment of a commission to examine the marshes on Staten Island and their effect on public health, the commission to consist of the state commissioner of health, state engineer and surveyor, the commission of health of New York City, and four men to be appointed by the governor.——The assembly passed the bill providing for the increase of salaries of all state hospital employes who are not affected by the increase made last year. As a result of the increase in wages made last year, an appropriation of about $30,000 has had to be made in the annual supply bill.

Personal.—Dr. Sarah R. Adamson Dolley, Rochester, the second woman in this country to receive a medical diploma, celebrated her diamond birthday a few days ago, when she was presented with a diamond brooch by her professional associates. She followed her profession for 49 years.——Drs. Percy L. Lang, Waverly, Daniel B. Murphy, Rochester, Pearse Bailey, New York City, and George Elmer Gorham, Albany, were appointed managers of the Craig Colony for Epileptics by Governor Odell.——Dr. James Wood, Mount Kisco, and Dr. Charles H. Turner, Albany, were appointed managers of the New York State Reformatory.——The Rt. Rev. Henry C. Potter, bishop of New York, was appointed manager of the New York State Hospital for the Care of Crippled and Deformed Children.——Dr. Edward J. Meyer, Buffalo, will make an extended visit to Europe.——Dr. Henry C. Buswell, Buffalo, leaves soon for a visit to Europe.——Dr. William C. Krauss, Buffalo, has returned from Mount Clemens.

New York City.

Babies' Hospital Needs Funds.—This institution, which treated last year 610 patients of the very poorest classes, received from its patients only $680 toward its support, and now sends out an urgent appeal for financial aid.

Office Building for Physicians.—The first building of this kind, called the Sydenham, will be completed next month. No one except physicians of recognized standing can obtain a lease. The committee in charge is composed of Drs. Robert T. Morris, Freeman F. Ward, Daniel Lewis, George H. Fox, and William B. DeGarno.

Contagious Diseases.—For the week ended March 26, 1,554 cases of measles were reported to the sanitary bureau, with 29 deaths; 494 of scarlet fever, with 25 deaths; 454 of tuberculosis, with 199 deaths; 87 of varicella, with no deaths; 21 of typhoid fever, with 9 deaths; 1 of smallpox, with no deaths, and 359 of diphtheria, with 44 deaths.

Hospital in Good Financial Condition.—A member of the staff of the Manhattan Eye and Ear Hospital notifies us that the institution is not in financial difficulties. He says: "We have not closed any ward for lack of funds to maintain it, or for any other reason. The institution is in a most flourishing condition, which is due to the generosity of its friends."

Dispensary Opened.—The new Mount Sinai Dispensary was opened March 27. There are in all 26 departments equipped with the most modern scientific appliances. This dispensary was the gift from the children of the late Mayor Leaman. The current report shows that during the past year there were treated 32,100 persons, and it is expected that in the new building *at least double that number will* be treated.

Another Abortionist Trapped.—The counsel of the county medical society, by a carefully laid trap, succeeded in securing the arrest of Dr. George H. Dolbeck, in West 28th Street, charged with attempting to perform a criminal operation.——Dr. Edward E. Conrad, whose case has been on trial this week for the same offense, has been found guilty and his sentence will be pronounced soon, which will be imprisonment for not more than two years, nor less than six months.——Dr. Blinn is now a fugitive from justice.

Personal.—Dr. George M. Lefferts, who recently resigned the professorship of laryngology in the College of Physicians and Surgeons, was given a handsome loving-cup, March 28, when he delivered his farewell lecture.——Drs. Linnaeus J. Hunter and James A. Kennedy have been appointed medical officers in the fire department at salaries of $2,000.——Dr. P. Ehrlich of Frankfort-on-the-Main, Germany, participated in the proceedings of the American Association of Pathologists and Bacteriologists.——Dr. Thomas L. Stedman and wife sailed for Europe April 3.

PENNSYLVANIA.

Philadelphia.

Changes in Health Bureau.—Dr. Edward Martin, director of public health and charities, has appointed Dr. John McClintock and Mary Pennington, Ph.D., assistant bacteriologists in the health department, to fill the positions made vacant by the resignations of Drs. John B. Stetson and T. D. Taggert.

College of Physicians to Move.—The College of Physicians, the oldest body of its kind in America, will abandon its time-honored quarters at Thirteenth and Locust streets and will erect a new building at Twenty-second and Ludlow streets. The new site cost $80,000. The society has $106,000 available for the new building, of which $50,000 was given by Andrew Carnegie.

Dr. Maragliano's Paper.—On March 28 Dr. Lawrence F. Flick, director of the Henry Phipps Institute, read Dr. Maragliano's paper before a large assembly of prominent medical men in the College of Physicians. Dr. Maragliano advocates serum therapy and vaccination for the prevention and treatment of the disease. From his researches on the question, both clinical and experimental, he is led to state: 1. That it is possible to produce a specific therapy for tuberculosis; and 2, that it is possible to immunize the animal organism against tuberculosis, as is done in other infectious diseases, and he has good reason to hope for an anti-tuberculous vaccination for man. Dr. Maragliano has shown from his investigation that it is possible in several ways to produce specific immunizing substances in man, but as yet it is impossible to say whether the resistance produced is sufficient or how long it will last. The Maragliano method of treatment is to be given a thorough test by Dr. Flick in his work at the Phipps institute.

Health Report—Typhoid Epidemic.—Since the first of the year, typhoid fever has prevailed to an alarming extent, and at the present time it is widely prevalent, indeed more so, in fact, than for many years. The prospects are that there will be little or no perceptible abatement in the disease until the entire city is supplied with more wholesome water. The present outbreak is widespread, covering every section of the city. The milk supply has been carefully investigated, and convincing proof has been obtained to show that it does not emanate from that source. There were 321 new cases recorded during the week ended April 2, with 24 deaths. During the preceding week there were 148 new cases and 17 deaths. The cases reported during the past week establish a new record, being 20 more than the greatest number during the epidemic of 1902; 32 new cases of smallpox were reported. This is a decrease of 2 over the previous 7 days. The death rate continues high. The total number for the week was 588, an increase of 3 over the preceding week, and an increase of 47 over the corresponding period of last year. The death rate from pneumonia also remains high, 96 persons having succumbed to the disease during the week.

Phipps Institute Dinner.—The anniversary dinner of the Henry Phipps Institute was given by the staff at the University Club, March 28. The delegates to the convention, which was called to consider the question of forming a national organization for the study of tuberculosis, were all invited as guests of the occasion. The feature of the evening was the presentation of a silver pitcher to Dr. Lawrence F. Flick, the director of the Henry Phipps Institute, by the members of the staff, as a token of their esteem. Mr. Henry Phipps, the founder of the institute, was present, and made the presentation in the name of the staff. Among those who spoke after dinner were Drs. Abraham Jacobi, New York City: William H. Welch, Johns Hopkins University; Vincent Y. Bowditch, Boston; John H. Pryor, Buffalo; Charles L. Minor, Asheville, N. C.; George M. Sternberg, former surgeon general of the U. S. Army; John B. Huber, New York; Leonard Pearson, state veterinarian of Pennsylvania; S. A. Knopf, New York; Samuel B. Ward, Albany; Henry B. Holton, Brattleboro, Vt.; John Henry Musser and James Tyson of the University of Pennsylvania, and James C. Wilson of Jefferson Medical College. Dr. L. F. Flick acted as toastmaster and chairman, and Dr. Mazyck P. Ravenel spoke for the staff of the institute.

WISCONSIN.

Half a Century in Practice.—Dr. Francis S. McNamara celebrated his semi-centenary of practice in Milwaukee, and his eighty-fifth birthday anniversary, March 12.

Ban on Public Gatherings.—The prevalence of scarlet fever at Delavan has caused the local health officer to close the public schools and to prohibit public gatherings of all kinds until the epidemic subsides.

Smallpox at Franksville.—German immigrants are said to have brought smallpox to Franksville. There are now 12 cases in that place, and many more have been exposed. The entire town is under strict quarantine.

Fined for Illegal Practice.—Morris J. Kalowsky, Milwaukee, charged with having practiced medicine without a license, pleaded guilty, and was given the minimum sentence, a fine of $50 and costs. He appealed to the Municipal Court.

Lectures on Tuberculosis.—The Wisconsin State Tuberculosis Commission is arranging to give a series of popular lectures on tuberculosis, the object being to educate the people and to arouse public interest in the establishment of a state sanatorium for consumptives.

GENERAL.

Hilo Hospital Closes.—The trustees of Hilo Hospital, Hawaii, have found it necessary, for financial reasons, to close the hospital.

Biloxi Sanitarium Burned.—The Biloxi Sanitarium, Biloxi, Miss., was destroyed by fire, April 5, all the patients being removed in safety.

To Enlarge Yokohama Hospital.—An enlargement from 25 beds to 500 has been decided on by officials of the U. S. Navy for the Yokohama Naval Hospital, and will be rushed to completion.

Mexico Cleans Up.—Tampico and other Mexican cities are undergoing a cleaning up at the hands of their sanitary authorities. Filth is being removed, stagnant pools drained or filled in, and systems of inspection installed.

Ankylostomiasis Investigation in Porto Rico.—The prevalence of ankylostomiasis in Porto Rico is to be the subject of an investigation under the charge of Captain Ashford of the Military Hospital. The government has appropriated $5,000 for the purpose.

Porto Rico Health Affairs.—Dr. Ricardo Hernandez, president of the Superior Board of Health of Porto Rico, has been appointed assistant director of health, charities and correction. Under the new law the Superior Board of Health becomes an advisory board to the director concerning sanitary investigations, and the causes of disease and its suppression.

United States Society for the Study of Tuberculosis.—For the purpose of discussing the question relating to organization for the study of tuberculosis in this country, the following met at the College of Physicians, Philadelphia, on the afternoon of March 28: From Philadelphia: Howard S. Anders, J. M. Anders, William M. Agney, L. Solis-Cohen, Solomon Solis-Cohen, W. M. L. Coplin, Frank A. Craig, Alex. H. Davisson, D. J. McCarthy, J. H. Musser, George W. Norris, Mazyck P. Ravenel, W. B. Stanton, James Tyson, T. Mellor Tyson, Joseph Walsh, W. B. Fetterman, Jr., Lawrence F. Flick, William B. Hackenburg, H. A. Hare, Charles J. Hatfield, H. R. M. Landis, Charles M. Lewis, J. M. Wilcox and J. C. Wilson. From New York City: J. Edward Stubbert, James Alex. Miller, Daniel Lewis, A. H. Doty, H. M. Biggs, A. Jacobi, Edward G. Janeway, S. A. Knopf and Alexander Lambert; also Henry D. Holton, Brattleboro, Vt.; Henry Barton Jacobs, Baltimore; Herbert M. King, Liberty, N. Y.; Charles H. Miner, Wilkesbarre, Pa.; Charles L. Minor, Asheville, N. C.; Estes Nichols, Augusta, Me.; William Osler, Baltimore; Jay Perkins, Providence; W. H. Peters, Providence; C. O. Probst, Columbus, Ohio; John H. Pryor, Ray Brook, N. Y.; DeLancey Rochester, Buffalo; Milton J. Rosenau, Washington; J. T. Rothrock, Mont Alto, Pa.; George M. Sternberg, Washington; Elwell Stockdale, White Haven, Pa.; Arthur K. Stone, Boston; J. M. Taylor, Boise, Idaho; Josephus T. Ullen, Germantown, Pa.; Samuel B. Ward, Albany, N. Y.; F. Forchheimer, Cincinnati; Albert C. Getchell, Worcester, Mass.; Henry G. Beyer, U. S. Navy; John J. Black, New Castle, Del.; Oliver A. Blumenthal, Syracuse, N. Y.; Vincent Y. Bowditch, Boston; M. J. Brooks, New Canaan, Conn.; Herbert C. Clapp and Agnes C. Vietor, Boston; William H. Welch, Baltimore; Francis H. Williams, Boston; B. H. Detweiler, Williamsport, Pa.; J. W. Ellenberger, Harrisburg, Pa. Prof. William Osler of Baltimore presided, and Dr. Henry Barton Jacobs of Baltimore acted as secretary. After a full discussion, participated in by Drs. Daniel Lewis, Minor, Flick, Knopf, Solomon Solis-Cohen, James Tyson, Stubbert, Pryor, Holton, Biggs, Rothrock, Jacobi, Janeway, Hare, Sternberg, Welch, Forchheimer, Ravenel, Rochester and Ward, Dr. Lawrence F. Flick of Philadelphia, offered the following resolution, which was seconded by Dr. Forchheimer and carried unanimously: "Resolved, that we here assembled do now organize ourselves into a United States Society for the Study of Tuberculosis." It was then moved by Dr. George M. Sternberg of Washington and seconded by Dr. Hare of Philadelphia "that the chairman appoint a committee of five to prepare a constitution and by-laws for such a society." This motion was carried unanimously. The chairman appointed Drs. Edward L. Trudeau, Herman M. Biggs, Lawrence F. Flick, William H. Welch and George M. Sternberg. It was further moved by Dr. Sternberg and carried unanimously "that the chairman and secretary of this meeting be ex-officio chairman and secretary of the committee." Dr. Ravenel then moved, and it was unanimously carried, "that it is the sense of this meeting that the committee call us together for organization at Atlantic City during the week of the session of the American Medical Association." The meeting then adjourned.

CANADA.

For Pure Food.—Both an American and a Canadian firm that were selling canned tomatoes, colored with anilin, in Montreal, are being prosecuted for fraud.

Medical Men Going Abroad.—Drs. J. Alex. Hutchinson and George E. Armstrong of Montreal, Murray McLaren of St. John, N. B., and W. G. Anglin of Kingston, will sail from Boston for Naples, April 9, and will journey through Italy, visiting the leading hospitals, and finally going to Vienna. Dr. Anglin has just recovered from a very severe attack of septicemia.

Military Medical Supplies.—The medical branch of the militia department has purchased a large supply of material and equipment that will add materially to the efficiency of this service. The purchases include eighteen ambulance wagons of a new type, designed by Lieutenant-Colonel Fiset, director general of the Canadian Army Medical Service, each wagon having room in it for four patients lying down, or thirteen sitting up.

Toronto Vital Statistics for March.—The following shows the comparison between the births, marriages and deaths in Toronto in March in 1903 and in 1904: Births, 377 and 437; marriages, 134 and 128; deaths, 366 and 354. As in 1903 there were no deaths from smallpox in March; scarlet fever, 2; diphtheria, 17; measles, 1; typhoid, 1; tuberculosis, 30; pneumonia, 42. The number of deaths five years and under, 126; over seventy years of age, 57. Deaths from pneumonia in January numbered 56; in February, 36; March, 42. The medical health officer states that Toronto has not been so free of scarlet fever for years.

Ontario Health Statistics for February.—During February only 680 divisions made returns to the Ontario Board of Health, and these show that the deaths were 2,332 in a population of 1,924,976, or at the rate of 14.4 per thousand. For the same month last year, a population of 1,941,632 reported 2,176 deaths. During February there were 41 cases of smallpox in the province in 11 places, with 1 death; 251 cases of scarlet fever in 62 places, with 13 deaths; 289 cases of diphtheria in 55 places, with 42 deaths. Measles was reported in 41 municipalities, with 1 death. Whooping cough occurred in 9 places, typhoid fever in 23, and consumption in 106.

No Adulteration Found in Canadian Liquors.—The department of inland revenue has issued a bulletin on distilled liquors. The samples analyzed consisted of rye whiskey, 91; white, 30; Scotch, 24; Irish, 2; gin, 27; rum, 12; brandy, 30; total, 216. Mr. McGill, who made the analysis, states that no deleterious substances have been found in these samples. In accordance with special instructions, he made an examination for alkaloids in all whiskey samples having less than 75 per cent. proof strength. A negative result was obtained in every case. He found some of the samples had been watered, particularly gin, which showed a noteworthy falling off in strength.

Ontario Physicians Fail to Report Typhoid Fever Cases.—Dr. Hodgetts, the secretary of the Ontario Board of Health, is endeavoring to enforce the law requiring all cases of infectious and contagious diseases to be reported. He finds that in 1902 there were announced to the department 1,542 cases of typhoid fever throughout the province, while the hospital statistics show 2,007 cases. In 1903 returns from the 700 divisions showed 1,012 cases, while in the hospitals there were 1,918 cases. He states that during the past few months several outbreaks of typhoid fever have been covered up by medical men failing to report, and that he may have to resort to prosecutions in order to wake up the physicians and to protect the public.

FOREIGN.

Plague in Peru.—Lima, Peru, is suffering from the plague. There were 32 cases in the week ended March 26 and 4 deaths March 30.

Ecuador Fights Mosquitoes.—Ecuador is carrying on an active campaign against yellow fever and malaria. Mosquitoes are being destroyed and circulars of information are being distributed, giving the regulations of the U. S. Public Health and Marine-Hospital Service.

More Plague in India.—The plague is said to be on the increase in India. For the week ended March 19 there were 40,527 deaths. The weekly rate in the Punjab and in the northwest provinces is 10,000 each, in the Bombay presidency the deaths number 8,500, and in Bengal 5,000.

Typhoid Fever at Paris.—There have been a number of cases of typhoid fever at Paris, the maximum in one week reaching 147. The proportion has been about one case per 10,000 inhabitants. One ward (Ménilmontant), although inhabited by the very poor, has always been remarkably exempt from typhoid fever, and this immunity was retained through the present epidemic.

Supervision of Infant Foods Needed in England.—At an inquest on the death of a child from convulsions, said to be due to the use of improper proprietary foods, held at the Wandsworth coroner's court, England, April 1, attention was called to the English laws which allow the sale, without supervision or inspection, of patent foods for children. The coroner said that such foods, sold by enticing advertisements, were responsible for the deaths of many children, and made the same statement about patent medicines. He urged that the government take up the matter.

A Mounted Red Cross Battalion.—A wealthy Russian has organized a mounted battalion, with 50 horses, to carry the wounded from the battlefield and give them medical aid. The horses carry folding litters, tents, etc. The officers of the company consist of 3 physicians, 4 assistants, 50 mounted attendants and 8 servants. Dr. W. Halle of Riga has charge of the medical department and the founder of the company, Mr. Rodzjanko, will lead it in person, besides paying all the expenses of its maintenance. The instruments were purchased in Berlin and Stockholm.

Vaccination Against Syphilis.—Metchnikoff inoculated a chimpanzee with virus from a baboon. No secondary manifestations have appeared during the ninety days since. Further inoculation with human virus has proved equally negative There is a possibility that the first inoculation from the baboon conferred immunity to the human virus. He is awaiting the arrival of a consignment of chimpanzees to repeat the experiments on a large scale. It will be remembered that Roux and Metchnikoff have devoted the large prizes bestowed on them last year to this research on anthropoid apes.

The Fourth International Home Relief Congress will be held at Edinburgh, June 7-10, with the object of discussing the ways in which aid can best be given the distressed poor in their own homes. The medical bearing of the following portion of the work planned makes it worth noting:

SECTION IV.—SICK ADULTS.

1. The Organization of the Home Treatment of Pulmonary Tuberculosis.
2. The Relation Between Hospital and Home Relief of Sick Poor.
3. The Best Scheme of Home Attendance on Puerperal Women in Larger Centers.

SECTION V.—INSANE AND EPILEPTICS.

1. The Best Method of Administering the System of Family Care of the Insane, and the Best System of Supervision.
2. After Care of Friendless Patients Discharged from Asylums
3. The Supervision and Home Care of Children and Young Adults Who Are Mentally Defective.
4. Epileptic Colonies.

Correspondence may be addressed to Edward T. Devine, 105 East Twenty-second Street, New York City.

LONDON LETTER.

Outbreak of Plague in Johannesburg.

An outbreak of plague in Johannesburg has caused considerable anxiety in England, as the strongly criticised intention of the government to import Chinese to work the mines has just been promulgated. Ten fresh cases are reported to-day.

and the mortality now amounts to 65 whites and 60 colored persons. The coolies are being rapidly removed to a new location outside the town. As the reports in The Journal show, plague has existed in South Africa for some years, though only in Port Elizabeth has it assumed considerable proportions. According to the last report no case of plague exists in Cape Colony, but rats are still reported as infected at Port Elizabeth and East London. In 1903 there were 135 deaths from plague in Cape Colony. Of these only 18 occurred in the last six months, so that the disease was declining. How the infection was carried to Johannesburg is not known. As adjacent districts are not infected it is thought to have been carried by rats in grain or other merchandise sent by rail. The disease is chiefly of the pneumonic variety.

Correspondence.

Cause of Increase in Pneumonia.

Indianapolis, March 28, 1904.

To the Editor:—A study of the Indiana mortality statistics and the morbidity and weather reports furnish data which seem to give some light on the cause of the recent marked increase in the pneumonia death rate.

Comparing the periods made up of November and December, 1900, and January and February, 1901, as the first period, and November and December, 1903, and January and February, 1904, as the second period I find that in the first there were 1,720 deaths, the weather was not severe, measles, influenza and "colds" were very prevalent and natural gas with no smoke was the almost universal fuel. The weather being mild, and the use of soft coal, as suggested by Dr. Lindsley of Connecticut, were not the cause of the increase in pneumonia which appeared in the period named. In the second period there were 1,784 pneumonia deaths, only 64 more than in the first, and the weather was very severe, soft coal was the universal fuel, and measles, influenza and colds very prevalent. It appears, therefore, that in the two periods separated by three years, they were closely alike in number of pneumonia deaths, also in the fact of prevalence of measles, influenza and "colds," but unlike in regard to weather and soft-coal smoke. Further, it appears from an examination of the death certificates of the two named periods, that an unusual proportion of pneumonia deaths among children occurred. For instance, in February, 1904, of the 711 pneumonia deaths 268 or 38.2 per cent., were under five years of age, and in February, 1901, there were 608 pneumonia deaths, with 237, or 39 per cent., under five years. Such a coincidence under the circumstances is certainly notable. In the two intervening Februarys, namely, of 1902 and 1903, we note fewer pneumonia deaths with blustering cold weather, plenty of coal smoke, but not a remarkable presence of measles, influenza and "colds" and a lower pneumonia death rate among the children. So far as Indiana is concerned it seems we are constrained to conclude that the increase in pneumonia attended the greater susceptibility caused by measles, influenza and "colds." J. N. Hurty,

Secy. Indiana State Board of Health.

Priority in Methods of Closure of Abdominal Wounds.

Philadelphia, April 1, 1904.

To the Editor:—In The Journal of the American Medical Association, March 12, p. 737, is an abstract of an article entitled "Abdominal Aponeuroses." The author of the article Dr. Winslow, seems to be unaware of the fact that his proposals of new methods and new principles in the closure of abdominal wounds are by no means novel. They have been in daily use in my hands for the last seven years, and intermittently, since 1894. The questions at issue were published by me in the *American Journal of Obstetrics*, April, 1897, the paper entitled "A New Method of Suturing the Abdominal Wall in Celiotomy," being read before the section of gynecology of the College of Physicians of Philadelphia, Jan. 21, 1897. The principles discussed by Dr. Winslow were further elaborated by me in a paper entitled "Remarks on the Influence of Technic on the Results of Closure of Wounds of the Abdominal Wall," read before the Obstetrical Society of Boston, Nov. 21, 1899, and published in the *Boston Medical and Surgical Journal*, March 8, 1900. These principles have been discussed by me on numerous occasions since these dates. Charles P. Noble.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PRIORITY AS TO TURTLE SERUM.

Charleston, Mo., April 2, 1904.

To the Editor:—In abstract 96, on page 136, of The Journal, Jan. 9, 1904, I see what I term an infringement on my rights as a discoverer. If you will consult The Journal you will see that I wrote the original article on "Turtle Serum," and among other things said that this serum was "specific" for all maladies, and just why a Dutchman and a foreigner should try to usurp my prerogative I am unable to see. The *Deutsche medicinische Wochenschrift*, of Berlin and Leipsic, is the journal from which you abstract this effort on the part of a foreigner to supplant a S. E. Missourian—a swamper. Now I feel that you have too much respect for Missouri and for one of its humble citizens to allow this foreigner (Dr. Friedmann) to undermine me in any such way. I informed your readers where they could get this "turtle serum," told them plainly of Dr. Rushe's phenomenal success, etc., and now here, at this late date, to see such effrontery as is displayed by Dr. Friedmann makes me tired. Please come to my relief and tell your readers that when it comes to "turtle serum" I am "cock of the walk" and can whip any man that dare trespass on my rights. W. P. Howle, M.D.

Answer.—Dr. Howle's claim of priority is based on his publication in The Journal, Nov. 1, 1902, p. 1124.

INTERFERENCE—GUARANTEEING CURE—BETTING.

April 2, 1904.

To the Editor:—A patient declined my services because I would not guarantee to cure him, and went at once to the office of a physician who professes great friendship for me and who is a member of the various societies. This physician told the patient he would not guarantee a cure, but would "bet him" (and did bet him, committing the agreement to paper and putting up the money) that he could cure him. Has the brother erred? He was aware of the patient's conduct with me. —— H.

Answer.—It is almost impossible to believe that a physician would thus gamble on the prospect of curing a patient. Our correspondent's statement is an *ex parte* one, and we should like to hear the other side before commenting to any extent. We may be allowed the general remark that either betting or guaranteeing a cure is incompatible with respectability and honor. As to the point whether the second physician had a right to take the case, this depends on whether the patient discharged our correspondent or not. If he did, any other physician could take the case.

REQUIREMENTS FOR PRACTICE IN MEXICO.

Sault Ste. Marie, Mich., March 25, 1904.

To the Editor:—Will you tell me through The Journal the requirements of the laws that govern the practice of medicine in old Mexico?

M. D. L.

Answer.—We believe that the practice of medicine in Mexico is free, but to have any legal standing and to be able to sign death certificates, to give testimony or to hold medical positions, one will have to pass an examination varying, we understand, in the different states. In the City of Mexico it is said to be rather severe in the Spanish language. There would probably be some inconveniences in general practice without such a license in certain states of the republic. In others, a license may be less a requisite.

REQUIREMENTS FOR PRACTICE IN CANADA.

Monroe City, Mo., April 1, 1904.

To the Editor:—Will you please inform me of the requirements to practice medicine in the northwest territory of Canada? If examination is required state date and place and name of secretary.

B. S. Lincoln.

Answer.—Unless one has a British or Canadian qualification he must possess a diploma recognized by the board from an institution requiring a four-year course and must pass an examination. We have not seen the list of recognized institutions. The registrar is J. D. Lafferty, M.D., Calgary, N.W.T., Canada.

RECIPROCITY IN NEW YORK, WISCONSIN AND MINNESOTA.

Run: New York does not reciprocate with any other state at the present time.

Colorado: *Minnesota has no provision for reciprocity in its* medical practice act. Wisconsin reciprocates with Ohio, but not with Colorado. Since these arrangements are dependent on the by-laws of the board they are liable to change.

POSTMORTEM ON A DEAD BODY.

A reader calls our attention to the following definition in Dorland's American Pocket Medical Dictionary: "Autopsy. Postmortem examination of a dead body." He asks us if the definition is correct. Yes, very much so.

FINSEN LIGHT LITERATURE.

Dr. A. W. Hammer, Philadelphia: *An article* on the Finsen light appeared in The Journal, April 12, 1902. Longmans, Green & Co., New York City, publish a book on "Finsen Phototherapy."

Marriages.

W. Ed. Grant, M.D., to Mrs. Daisy D. Walker, both of Louisville, March 24.

Carlton W. Cragg, M.D., to Miss Aline Williams, both of Cincinnati, March 24.

Reginald Stonestreet, M.D., Paragon Mills, Tenn., to Miss Carrie Savage of Nashville, March 23.

Mark D. Ethridge, M.D., to Miss Mary Elizabeth Bostick, both of Sandersville, Miss., March 24.

Greer Baughman, M.D., Richmond, Va., to Miss Wilhelmina Agnes Reeve of Washington, D. C., April 6.

James Edward Gill, M.D., U. S. Navy, to Miss Lucy Hamilton Armes of Birmingham, Ala., March 24.

Bernard Singleton Gostin, M.D., Macon, Ga., to Miss Katharine Elizabeth Dewson of New York City, April 4.

Deaths.

Louis A. Kengla, M.D. University of Georgetown, Washington. D. C., 1886, a member of the American Medical Association and editor of the *Occidental Medical Times*, died at his home in San Francisco, March 26. The *Sacramento Bee*, in an editorial comment on his death, pays the following tribute:

> The fearless and broad-minded course he pursued with regard to bubonic plague in San Francisco commended him to the esteem of the profession and the gratitude of the public. From the first he stood for the policy of telling the truth, and denounced the miserable attempts at concealment and falsification which for a time threatened to result in a general eastern quarantine against this state. In adhering to this sound and honest course he suffered in business and was exposed to much annoyance, but he never faltered in his uncompromising, unflinching devotion to right and duty. He had the satisfaction of living to see vindication of the truth and official recognition by the state health authorities of the existence of the disease whose presence has so long been falsely and foolishly denied by the press of the city.

John Metcalf Polk, M.D. Cornell University Medical College, New York, 1899, died from *pneumonia* at his home in New York City, March 29, after an illness of ten days, aged 28. Dr. Polk was the son of Dr. William M. Polk, and graduated second in his class. He served as interne in Bellevue Hospital, and was afterward made adjunct assistant physician to that institution. During the past winter he had been conducting experimental research on the hemolytic action of the blood in infectious diseases. This work, which promises to be of value, was practically completed at the time of his death.

Abram B. Arnold, M.D. Washington University School of Medicine, Baltimore, 1848; president of the Baltimore Medical Association, 1871-1872; president of the Medical and Chirurgical Faculty of Maryland, 1877-1878; professor of practice of medicine in Washington University, 1872-1877; professor of nervous diseases, College of Physicians and Surgeons, 1877-1889, and afterward professor emeritus; a practitioner of repute, and a linguist of note, died at his home in San Francisco, March 28, aged 84. From 1848 to 1902 he practiced in Baltimore.

Charles C. Carter, M.D. Bellevue Hospital Medical College, New York, 1876, assistant surgeon general of Illinois; a member of the American Medical Association, Association of Military Surgeons of the United States, Illinois Association of Military Surgeons, Illinois State Medical Society; Iowa and Illinois Central District Medical Society and Rock Island County Medical Society; a prominent and beloved physician of Rock Island, died at his home in that city, April 2, from pneumonia, after an illness of six days, aged 51.

Israel Parsons, M.D. College of Physicians and Surgeons, New York, 1848, a member of the New York State and Onondaga County medical societies, and the Syracuse Academy of Medicine, died at his home in Marcellus, N. Y., March 20, after an illness of five days, aged 82. In 1899 the Onondaga County Medical Society gave a banquet in honor of Dr. Parsons' semi-centenary in medicine.

Stephen Paul Truex, M.D. Long Island College Hospital, Brooklyn, 1891, of Brooklyn, instructor in general surgery and surgical anatomy in the Post-Graduate Medical School and Hospital, member of the Kings County Medical Society, and gynecologist to Bushwick Central Hospital, Brooklyn, died suddenly while performing an operation in that institution from acute dilatation of the heart, March 31, aged 48.

Arthur R. Simmons, M.D. College of Physicians and Surgeons, New York, 1875, Utica, N. Y., died at his home in that city, March 27, from heart disease. The Utica Medical Library Association held a memorial meeting, March 29, at which tributes were paid to the memory of Dr. Simmons, and resolutions were adopted by the medical staff of St. Luke's Hospital.

Elijah P. Noel, M.D. Starling Medical College, Columbus, 1890, expert in the office of the city attorney, Chicago, coroner's physician of Cook County from 1896 to 1900, assistant professor of physiology at Rush Medical College, died from tuberculosis, March 29, at Phoenix, Ariz., after an illness of seven years, aged 39.

Washington H. Baker, M.D. University of Pennsylvania, Philadelphia, 1875, for several years assistant to Professor Penrose in the University Hospital; visiting physician to St. Joseph's Hospital, and a surgeon in the Second Infantry, N. G. Pa., died March 31, at his home in Philadelphia, from apoplexy, aged 52.

Percy L. Jermane, M.D. Jefferson Medical College, Philadelphia, 1892, of Holton, Kan., a member of the American Medical Association, and one of the foremost surgeons of Northeastern Kansas, died at Stormont Hospital, Topeka, March 22, from general peritonitis following an operation for appendicitis, aged 36.

Harry J. Chapman, M.D. University of Pennsylvania, Philadelphia, 1895, of San Antonio, Texas, formerly physician to Winyah Sanitarium, Asheville, N. C., a member of the American Medical Association, and of the Texas Medical Association, was shot and instantly killed, while driving, March 25, aged 37.

John Paul Dombrowski, M.D. University of Berlin, Germany, 1880, a member of the American Medical Association, one of the most prominent specialists on diseases of the eye in central Illinois, died at his home in Peoria, March 28, from pneumonia, after an illness of ten days, aged 47.

David Mackay, M.D. University of Glasgow, Scotland, 1855, surgeon in the Crimean and Civil wars; later city physician of New Orleans, and for six years surgeon general of the Grand Army of the Republic, died at his home in Dallas, Texas, March 23, aged 71.

George H. Butler, M.D. Bellevue Hospital Medical College, New York, 1869, a member of the New York County Medical Society and New York Academy of Medicine, died at his home in New York City, from throat disease, March 28, aged 61.

Albert Stanley Dolan, M.D. University of Michigan Homeopathic Medical College, Ann Arbor, 1882, formerly assistant at the Southern California Hospital for the Insane, died at Riverside, Cal., March 21, from heart disease.

Charles E. Wetton, M.D. New York Homeopathic Medical College and Hospital, 1902, Syracuse, N. Y., died at the Hahnemann Hospital, New York, March 26, from cerebral hemorrhage, after an illness of four weeks, aged 41.

John G. Brooks, M.D. Jefferson Medical College, Philadelphia, 1851, ex-mayor of Belfast, Maine, state senator in 1873, and representative in 1880, died at his home in Belfast, March 23, after a long illness, aged 83.

Lawrence L. Glover, M.D. Jefferson Medical College, Philadelphia, 1882, ensign and assistant surgeon in the Naval Reserve of New Jersey, died at his home in Haddonfield, N. J., March 21, from pneumonia, aged 37.

Alfred Duperier, M.D. Tulane University, New Orleans, 1847, who rendered effective service in the yellow fever epidemics of

1853 and 1867 in southwestern Louisiana, died at his home in New Iberia, La., aged 77.

Harry S. Dissler, M.D. Medico-Chirurgical College, Philadelphia, 1903, of Schoeneck, Pa., died from acute nephritis at the Medico-Chirurgical Hospital, Philadelphia, at which he was resident physician, March 20, after an illness of one week, aged 22.

J. W. Crowley, M.D. St. Louis Medical College, 1867, chief surgeon of the Thirteenth Missouri Cavalry in the Civil War, died suddenly in Cairo, Egypt, March 15, after an extended period of ill health.

Morris Silk, M.D. College of Physicians and Surgeons, New York, 1902, resident physician at Hart's Island, died at his home in New York City, March 28, after an illness of eight weeks.

John R. Jones, M.D. University of Pennsylvania, Philadelphia, 1858, surgeon in the Confederate service during the Civil War, died at his home in Emporia, Va., March 25, aged 69.

John A. Anthony, M.D. Rush Medical College, Chicago, 1887, for 15 years at Chenoa, Ill., died at a hospital in Boise, Idaho, where he had recently located, from pneumonia, March 26.

Clinton Munson, M.D. Hahnemann Medical College, Chicago, 1872, of Tacoma, Wash., died from septicemia after a long illness in a sanatorium in San Francisco, March 20.

John T. Steele, M.D. University of Pennsylvania, Philadelphia, 1879, who retired from practice several years ago, died at his home in Pulaski, Tenn., March 10, aged 78.

Emil A. Haag, M.D. Kentucky School of Medicine, Louisville, 1892, of Indianapolis, died suddenly from heart disease at the home of his mother in that city, April 3, aged 41.

Joseph W. Sharp, M.D. University of Pennsylvania, Philadelphia, 1850, died from asthma after a long illness at his home in Dayton, Pa., March 2, aged 69.

Mills Olcott Carter, M.D. Dartmouth Medical College, Hanover, N. H., 1863, surgeon during the Civil War, died recently at his home in Lowell, Mass., aged 64.

John H. Hunter, M.D. Atlanta (Ga.) Medical College, 1888, died at his home in Powder Springs, Ga., March 23, from consumption, after a long illness.

W. F. Dohrmann, M.D., of San Francisco, died at his home in Santa Barbara, Cal., March 26, from pneumonia, after an illness of one week, aged 35.

Emil Schottenfels, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1874, died at his home in Chicago, March 31, from pneumonia, aged 74.

Mary Denison Moss, M.D. Boston University School of Medicine, 1875, died at her home in Providence, R. I., from heart disease, March 25, aged 64.

Elmer E. Prescott, M.D. Rush Medical College, 1893, died at his office in Chicago, from the effects of atropin, self-administered, March 30, aged 41.

Austin D. Smith, M.D. Geneva (N. Y.) Medical College, 1869, died suddenly at his home in East Pembroke, N. Y., March 25, from apoplexy, aged 73.

Morris Bailey, M.D. Penn Medical University, Philadelphia, 1865, died at his home in Titusville, Pa., March 17, after a long illness, aged 85.

Birney R. Goold, M.D. Rush Medical College, Chicago, 1896, died from heart disease at his home in Chicago, March 29, after a short illness.

Solomon P. Allen, M.D. Geneva (N. Y.) Medical College, 1867, died at his home in Lestershire, N. Y., March 23, after a long illness, aged 59.

Frederick H. Austin, M.D. Indiana Eclectic Medical College, Indianapolis, 1885, was found dead in his office in Jamestown, Ind., March 26.

Mark J. Bixby, M.D. College of Physicians and Surgeons, Boston, died recently at his home in West Fairlee, Vt., from paralysis.

W. W. Nash, M.D. Kentucky School of Medicine, Louisville, 1882, died from pneumonia at his home in Pheba, Miss., March 28.

William B. Burland, M.D. McGill University, Montreal, 1872, died at his home in Montreal, March 19, from pneumonia, aged 59.

Edward P. Woodward, M.D. Yale Medical School, New Haven, 1860, retired, died at his home in Bristol, Conn., March 19, aged 67.

John Gilwee, M.D. St. Louis Medical College, 1876, died suddenly at his office in St. Louis, March 25, from heart disease, aged 68.

Winfield R. Robison, M.D. Medical College of Georgia, Augusta, 1875, died recently at his home in Milledgeville, Ga.

Louis D. Cyr, M.D., the oldest physician of the Upper Peninsula, died at his home in Negaunee, Mich., March 27, aged 68.

Edwin B. Mack, M.D. University of Vermont, Burlington, 1887, died recently at his home in Woodstock, Vt., aged 42.

Giovanni Demaglianis, M.D. University of Parma, Italy, 1890, of Coal City, Ill., died recently at South Wilmington, Ill.

Harry J. Combel, M.D. Tulane University, New Orleans, 1897, died at his home in New Orleans, March 24, aged 28.

J. J. Buster, M.D. Medical College of Georgia, Augusta, 1883, died recently at his home in Mount Willing, S. C.

C. H. Roberts, M.D., died suddenly at his residence in Wolfe City, Texas, March 25, from heart disease.

Nathaniel T. Clarke, M.D., died at his home in North Syracuse, N. Y., February 25, aged 76.

Isaac Sides, M.D., retired, died at his home in Colon, Mich., March 22, aged 84.

Book Notice.

The Complete Anas of Thomas Jefferson. Edited by Franklin B. Sawvel, Ph.D. Cloth. Pp. 283. Price, $1.50. New York: The Round Table Press. 1903.

This is a compilation of notes jotted down by Thomas Jefferson during the important period of 1791 to 1809. The anas are items of "passing transactions," private notes, opinions on current topics—just such items as one would record in a well-kept diary, but instead of being written in a book, they were put "on loose scraps of paper taken out of my pocket in the moment, and laid down to be copied fair at leisure, which, however, they hardly ever were." They are interesting and instructive as showing the personal views of one who helped to mold the opinion of men who founded our government and who framed the constitution under which we live. A brief biographical sketch of Jefferson is given, and his first inaugural address appears as an appendix. The editor could have made the work much more instructive had he inserted explanatory footnotes occasionally; as it is, many of the "notes" are unintelligible since the reader is in the dark regarding the subject matter. Another serious fault, and it is inexcusable, is that there is no index. The book is well gotten up, is well printed and bound, and makes a handsome appearance.

Association News.

Atlantic City Hotels.

For a list of the hotels at Atlantic City and their prices, see The Journal, April 2, page 912.

Other Meetings at Atlantic City.—The Gastro-Enterological Association.

In addition to the full section programs of the American Medical Association at the annual session at Atlantic City, June 7 to 10, additional attraction for the visitor is found in the other societies that are to meet there at about the same date. The American Gastro-Enterological Association is one of these; it will meet June 6 and 7, and the chief subject on the preliminary program is "Gastric Ulcer." There will be a symposium in some fifteen or more subdivisions by as many well-qualified men.

New Members.

List of new members for the month of March, 1904:

ALABAMA.

Lindsey, E. C., Florence.
Maxwell, C. K., Kellyton.
Pugh, B. B., Ironaton.
Odom, J. N., America.
Perry, H. G., Greensboro.
Henderson, S. C., Brewton.

ARKANSAS.

Wootton, W. T., Hot Springs.
Jennings, Ches., Little Rock.
Jones, Edw. D., Russellville.
Latimer, Newton J., Corning.
Hightower, Wm. M., Grapevine.

CALIFORNIA.

King, Jos. M., Los Angeles.
Fox, W. H., Los Angeles.
Lang, Paul, Oakland.
Dell, Lillian A., Oakland.
Perry, Alf. W., San Francisco.
Steltzner, Emil, San Francisco.
Buckley, V. P., San Francisco.
Hill, Harold P., San Francisco.

Quinan, Clarence, San Francisco.
Woolsey, C. H., San Francisco.
Lawry, Olin J., Redding.
Snow, Wm. F., Standford Univ.
Wickman, W. J., San Rafael.
Delamere, Henry S., Ferndale.

COLORADO.

Moore, T. B., Canon City.
Keller, Wm. N., Salida.
Edwards, J. L., Florence.

CONNECTICUT.

Down, Edwin A., Hartford.
Winne, Wm. N., New Haven.
Bartlett, Chas. J., New Haven.

DISTRICT OF COLUMBIA.

Hunt, Reid, Washington.
Gill, Wm. T., Washington.

FLORIDA.

Bartlett, Chas. W., Tampa.
Caldwell, Frank H., Tampa.
Newson, W. V., Ocala.
Smith, Dan M., Ocala.
Peek, Leon A., Melbourne.
Waggener, Richard, Warrington.
Glover, Geo. B., Monticello.
Welch, Geo. E., Palatka.
Howard, N. de N., Sanford.
Harris, R. L., Orlando.
Kennedy, S. R. M., Pensacola.

GEORGIA.

Van Dyke, Arthur H., Atlanta.
Crawford, J. M., Atlanta.
Johns, J. H., Atlanta.
Hoke, Michael, Atlanta.
Bradley, J. H., Macon.
Weichselbaum, J., Savannah.

IDAHO.

Stoneburner, J. N., Leland.

ILLINOIS.

Colloran, J. Edgar, Chicago.
Ladova, Rosalie M., Chicago.
Guagliata, Vincent, Chicago.
McGowan, M. J., Chicago.
Wynekoop, C. I., Chicago.
Brown, F. I., Chicago.
Harvey, And. M., Chicago.
Haag, Frances J., Edwardsville.
Davis, Homer W., Alton.
Wilson, Harry E., Sandoval.
Friend, Wm., Sumner.

INDIANA.

Fry, Berna C., Indianapolis.
Scott, Eueldas K., Hartford City.
Button, C. E., Crown Point.
Kurtz, F. B., Princeton.

IOWA.

Walker, Harry T., Dubuque.
Hibbs, G. B., Mitchellville.
Hill, Wm. F., Beaman.
Hansen, Andreas S., Waterloo.
Pease, C. I., Linn Grove.
Bishop, Carl S., Glasgow.
Foley, Fred. C., Newell.
Harvey, Leonard J., Alta.
Reid, Duncan, New Hartford.
Strout, A. O., Parkersburg.
Hanson, A. W., Hanlontown.

KANSAS.

Snider, S. J., Courtland.
Gaines, F. M., Solomon.

KENTUCKY.

McKinney, Wm. Thos., Louisville.
Pfingst, Adolph O., Louisville.
Quinby, S. C., Louisville.
Duncan, Ellis, Louisville.
Smock, B. W., Louisville.
Overall, John B., Dacon.

Amesse, J. W., asst.-surgeon, granted leave of absence for two months and fifteen days from May 1.

Boggess, J. S., asst.-surgeon, granted leave of absence for two days from March 30.

BOARDS CONVENED.

Board to meet at Washington, D. C., to consider the construction or purchase of boarding steamers for the quarantine stations at San Francisco and Port Townsend, Wash.; also to consider type of launch for boarding or inspection of vessels at the Key West Quarantine and at Havana, Cuba; also to consider the feasibility of repairing the hull of the launch *Spray* at the Delaware Breakwater Quarantine, and placing new motive power therein. Detail for the board: Asst.-Surgeon-General A. H. Glennan, chairman; Asst.-Surgeon-General W. J. Pettus; Asst.-Surgeon-General H. D. Geddings, recorder.

Board convened at Baltimore, April 4, for the physical examination of officers of the Revenue-Cutter Service for promotion. Detail for the board: Surgeon H. R. Carter, chairman; Asst.-Surgeon C. W. Wille, recorder.

Board convened at San Francisco, April 4, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-Surgeon Carl Ramus, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended April 1, 1904:

SMALLPOX—UNITED STATES.

Colorado: Denver, Jan. 30-Feb. 27, 22 cases, 1 death.

Florida: Jacksonville, March 19-26, 1 case.

Illinois: March 19-26, Chicago, 10 cases; Galesburg, 3 cases.

Kentucky: Burlington, to March 28, 16 cases; Covington, March 19-26, 3 cases; Springfield, March 28, 6 cases.

Louisiana: New Orleans, March 19-26, 2 cases, imported.

Maine: Manawaska region, March 19-26, 2 cases.

Maryland: Baltimore, March 19-26, 3 cases.

Massachusetts: Lowell, March 19-26, 1 death.

Michigan: March 19-26, Detroit, 2 cases; Grand Rapids, 2 cases; March 12-19, at 82 localities, present.

Missouri: St. Louis, March 19-26, 4 cases.

New Jersey: March 19-26, Camden, 2 cases, 1 death; Trenton, 1 case; Jersey City, March 20-27, 1 case, porter on train.

New York: New York, March 19-26, 1 case.

Ohio: Cincinnati, March 11-18, 1 case, 1 death; Cleveland, March 18-25, 5 cases; March 19-26, Dayton, 8 cases, 1 death; Warren, 1 case; Lorain, March 20-27, 2 cases, probably imported.

Pennsylvania: March 19-26, Johnstown, 2 cases; Philadelphia, 35 cases, 8 deaths; Pittsburg, 8 cases, 1 imported.

South Carolina: Charleston, March 19-26, 4 cases, 1 death; Greenville, March 12-19, 4 cases.

Tennessee: March 19-26, Memphis, 30 cases, 1 death; Nashville, 2 cases.

Wisconsin: Milwaukee, March 19-26, 3 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, March 5-12, 4 cases, 3 deaths.

Colombia: Barranquilla, Feb. 20-March 13, 1 death.

France: Lyons, Feb. 27-March 5, 1 death; Paris, March 5-12, 32 cases, 3 deaths.

Great Britain: March 12-19, Birmingham, 1 case; Cardiff, 1 case; Glasgow, March 11-18, 21 cases, 2 deaths; March 5-12, Edinburgh, 6 cases, 1 death; Hull, 7 cases; Leith, 1 case; London, 21 cases; Manchester, 3 cases; Newcastle-on-Tyne, 3 cases; Nottingham, 18 cases, 3 deaths; South Shields, 3 cases.

India: Bombay, Feb. 23-March 1, 14 deaths; Karachi, Feb. 21-28, 1 case, 1 death.

Java: Batavia, Feb. 13-20, 20 cases, 8 deaths.

Mexico: City of Mexico, March 6-13, 16 cases, 7 deaths.

Netherlands: Amsterdam, March 12-19, 3 cases, 3 deaths.

Russia: Feb. 27-March 5, Moscow, 8 cases, 3 deaths; St. Petersburg, 12 cases, 1 death; Odessa, March 5-12, 1 case.

Spain: Santander, March 7-14, 4 cases, 1 death.

Turkey: Alexandretta, March 5-12, 1 case; Constantinople, March 6-13, 8 cases; Smyrna, Feb. 21-28, 1 case.

YELLOW FEVER.

Ecuador: Guayaquil, Feb. 27-March 5, 3 deaths.

Mexico: Vera Cruz, March 12-19, 1 case.

CHOLERA.

India: Calcutta, Feb. 13-20, 34 deaths; Karachi, Feb. 21-28, 2 cases, 1 death; Madras, Feb. 13-20, 3 cases, 1 death.

Turkey in Asia: Feb. 22, Bassra, 7 cases, 7 deaths; Kermit Ali, 4 cases, 2 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Feb. 6-13, 1 case, 1 death.

PLAGUE—FOREIGN.

China: Hongkong, Feb. 6-13, 2 deaths.

India: Bombay, Feb. 23-March 1, 832 deaths; Calcutta, Feb. 13-20, 75 deaths; Karachi, Feb. 21-28, 113 cases, 96 deaths; Rangoon, Feb. 19, 1 case.

Mauritius: Feb. 18-25, 3 cases, 2 deaths.

Peru: Lima, March 31, 28 cases reported.

Medical Organization.

Medical Society of the Missouri Valley.—At the seventeenth annual meeting of this society held in Lincoln, Neb., March 24, the following preamble and resolutions were unanimously adopted:

WHEREAS, At the present time there is a most praiseworthy effort being made to federate, unify and bring into one grand, compact organization the entire medical profession of America; and

WHEREAS, The promoters of this great work in the various state and county societies, and in the American Medical Association, have met with unqualified success, as evidenced by the fact that already there are enrolled over 200 component societies; therefore, be it

Resolved, That the members of the Medical Society of the Missouri Valley are in sympathy with this progressive movement, and heartily endorse the plan of organization. Be it further

Resolved, That this society desires to become a district or auxiliary society in affiliation with the American Medical Association.

Florida.

Dr. J. Harris Pierpont, councilor of the First District, reports the organization of the Walton and Washington county medical societies. This completes his district, except one county, which has too few physicians to form a society.

WALTON COUNTY MEDICAL SOCIETY.—This society was organized, March 18, with the following officers: Dr. George P. Henry, president; Dr. C. A. Landrum, vice-president, and Dr. W. H. Stinson, secretary-treasurer, all of De Funiak Springs.

WASHINGTON COUNTY MEDICAL SOCIETY.—This society was organized, March 18, at Chipley, with the following officers: Dr. F. C. Wilson, president; Dr. J. H. Farrier, vice-president, and Dr. J. S. McGeachy, secretary-treasurer, all of Chipley.

Missouri.

HANNIBAL MEDICAL SOCIETY.—This society has been reorganized on the standard plan with the following officers: Dr. John S. Howell, president; Dr. Florence Janet Reid, secretary, and Dr. John J. Bourn, treasurer.

Montana.

Montana, North District, Medical Society.—A meeting was held at Great Falls, March 24, to reorganize this society, which has been inactive for several years. Dr. John A. Sweat was made temporary chairman, and Dr. Charles T. Sweeney temporary secretary, both of Great Falls. Dr. Ernest Crutcher, Great Falls, representing the Montana State Medical Association, presented the constitution and by-laws of that body, and a committee on by-laws was appointed, consisting of Drs. Albert F. Longeway, Earle Strain, and Charles T. Sweeney, all of Great Falls.

Texas.

Colorado County Medical Association.—The organization of this association was noted in The Journal of March 26. Dr. Robert H. Harrison, Columbus, was elected president; Dr. Charles G. Cook, Weimer, vice-president; Dr. Charles M. Blair, Columbus, secretary; Dr. Robert H. Harrison, Jr., Columbus, delegate to the state association, and Drs. Harry R. Bowers, Columbus, Charles A. Williamson, Columbus, and Samuel B. MacLeary, Weimar, were elected censors.

Fifteenth District Medical Society.—Pursuant to a call issued by Dr. Holman Taylor, Marshall, councilor of the Fifteenth (Northeastern) District, delegates from the seventeen counties which make up the district met at Marshall, March 21, and passed resolutions proposing that the Northeast Texas Medical Association be constituted the official medical society of the Fifteenth District on its compliance with the standard by-laws. Dr. William G. Jameson, Palestine, was elected chairman, and Dr. E. H. Hamilton, Longview, secretary of the temporary organization.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Chronic Dyspepsia in Children.

In the treatment of chronic dyspepsia in children, which term includes all the digestive disorders of childhood which are not acute, and not merely symptomatic, W. R. Jordan, in *Merck's Archives*, states that drug treatment is necessary in all cases. During an actual catarrhal attack, or where the subjective symptoms are prominent, the author recommends the following to be given three times a day before meals:

℞.	Sodii bicarb.	gr. vi	40
	Tinct. nucis vom.		
	Spts. chloroformi, āā	gtt. ii	12
	Aq. menth. pip. q. s. ad	ʒii	8

M. Sig.: *At one dose, to be repeated before each meal.*

If constipation is present it must be corrected. For this purpose he recommends cascara combined as follows:

℞.	Ext. cascaræ sagradæ flu.	m. x	65
	Tinct. nucis vom.	m. ii	12
	Tinct. belladonnæ	m. v	30
	Glycerini	m. x	65
	Aq. menth. pip. q. s. ad	ʒii	8

M. Ft. haustus. Sig.: To be taken at one dose, at bedtime.

In some cases the constipation may be relieved by *the administration* of rhubarb or magnesia before meals.

When the constipation has been corrected the following should be prescribed to increase the strength and appetite of the patient:

℞.	Tinct. ferri chloridi	gtt. lxxv	5
	Liq. strych. (1 per cent.)	gtt. xv	1
	Aq. chloroformi q. s. ad	℥iv	120

M. Sig.: Two teaspoonfuls after each meal in water.

Where headaches of more or less distinctly periodic type complicate the condition, the author recommends antipyrin in 5 grain (.30) doses two or three times daily. The diet must be regulated by the prohibition of sweets, pastry, pickles and tea *especially during the attack*. In severe cases the diet may be restricted to beef tea and mutton broth, with dry toast, gradually introducing milk and meat into the diet. Later and in milder cases the following rules should be observed: Meals at regular intervals, not too long; nothing between meals; no tea or coffee, no pickles, no sauces or highly seasoned food. Potatoes should be eliminated from the diet until convalescence. The abdominal organs and thighs should be well protected by the clothing, while not too thick and heavy over the chest. The parents should then be instructed to take the child out of doors into the open air to a generous extent. Children under *eight should* be kept away from school, and no child should be allowed to go to school who is described as eating "no breakfast."

Eczema.

Gaucher, in *Jour. de Pract.*, in speaking of the treatment of eczema, states that in eczema of the scalp the crusts should be removed by applying compresses dipped in hot water and covered with rubber tissue. In *women the crusts* are best removed by the aid of oily and emollient applications, and by *local* applications of steam. After removing the crusts the author recommends the application of the following to the scalp:

℞.	Olei cadini	ʒv	20
	Olei amygdalæ exp.	℥i	30

M. Sig.: Apply locally night and morning.

The same treatment may be pursued in eczema of the beard *and eyebrows. In these latter forms* the following ointment is of service:

℞.	*Zinci oxidi*	ʒiss	6
	Hydrarg. chloridi mitis	gr. xlv	3
	Adipis	℥iiss	75

M. Sig.: Apply locally.

In sycosis of the beard the following is recommended:

℞.	Hydrarg. subsulph. flavi	gr. xv-xlv	1.-3
	Adipis	℥i	30

M. Sig.: Apply locally.

In eczema of the nostrils, after syringing the nose with borated water, apply pieces of cotton saturated with the following ointment:

R.	Acidi borici		
	Acidi tannici		
	Hydrarg. chloridi mitis		
	Zinci oxidi, āā	gr. x	65
	Liq. petrolati	gr. c	6|65

M. Ft. unguentum. Sig.: Apply on pledgets of cotton; or:

℞.	Acidi salicylici	gr. i-v	06-.30
	Liq. petrolati	℥i	30

M. Sig.: Apply locally to the affected areas on pledgets of cotton.

In the treatment of eczema of the lips use an application of an ointment of boric acid or of zinc oxid 10 per cent. or of salicylic acid ointment 1 per cent. strength. At night the lips should be protected by a rubber band. When eczema attacks the eyelids compresses of hot water and linden flowers or boric acid should be applied locally, and the following solution dropped into the eye:

℞.	Aluminis (burnt)	gr. i	06
	Aquæ destil.	ʒii	8

M. Sig.: Drop one drop into the inner angle of the eye night and morning.

When the eyelashes are involved they should be epilated and the yellow oxid of mercury applied locally or cauterization with copper sulphate. When the auditory canal is attacked, an infusion of althea should be employed together with applications of the oil of cade.

In the acute stage of eczema of the anus moist compresses must be applied locally and later on the application of the oil of cade; or an ointment of calomel, or of the extract of krameria. When fissure exists cauterization of the fissure with copper sulphates should be resorted to. To relieve the itching a 5 per cent. chloral solution or a 10 per cent. solution of carbolic acid should be applied locally. To relieve the subjective symptoms and to effect a cure when the scrotum is involved moist applications should be applied, together with ointments of zinc oxid or bismuth subgallate. If the eczema is dry, apply dilute oil of cade, and, if moist, a powder consisting of 2 parts per 100 of salicylic acid.

When the glans is involved local baths are recommended three times daily with a solution of resorcin, 1-200, and in the intervals *the following powder* should be applied:

℞.	Mag. carb.	℥i	30
	Aristol	gr. xxx	2

M. Sig.: Apply locally after the bath.

And when involving the vulva in the female, compresses of a saturated solution of boric acid or of chloral, 1-200, should be applied, followed by *ointments* of zinc oxid or calomel or bismuth subgallate.

To relieve eczema occurring on the lower extremities, rest in bed is indicated, wet compresses and the following ointment:

℞.	Olei cadini	ʒiiss	10
	Zinci oxidi	℥ss	15
	Liq. petrolati	ʒv	20

M. Ft. unguentum. Sig.: Apply locally.

And when eczema attacks the palms and soles, the parts should be washed with a solution of the tincture of green soap night and morning. Later, oil of cade or a 2 per cent. ointment of salicylic acid may be applied. When the nails are involved an application of pure oil of cade or a 5 per cent. solution of salicylic ointment serves the purpose.

Brodier, in *Med. Age*, recommends internal treatment in eczema occurring in gouty and rheumatic cases. His list of preparations includes quinin, colchicum, digitalis, ergot, and belladonna.

Brocq, in the same periodical, recommends the following combination:

℞.	Quin. hydrobrom.	gr. i	06
	Ext. colchici	gr. 1/6	01
	Pulv. digitalis fol.	gr. 1/3	02

M. Sig.: Two or three such pills daily; or:

℞.	Quin. hydrobrom.	gr. i	06
	Ext. belladonnæ	gr. 1/60	001
	Ext. gentianæ	gr. i	06

M. Sig.: One such pill four to eight times daily.

Arsenic and sulphur must be avoided, according to the author, in all acute eczemas. A milk diet should be advised. The local treatment in the beginning should consist of starch cataplasms applied on muslin and removed every three or four hours. Chamomile lotion is also of service. In old arthritic cases powders are better than cataplasms. The best are starch and lycopodium, which may be mixed with zinc oxid, bismuth and camphor. Ointments such as the glycerol of starch, unguentum aquæ rosæ, or a mixture of zinc oxid, starch, and lanolin are useful. Picric acid 1-200 solution is good in acute eczema, not accompanied by much inflammation, to relieve the itching.

Medicolegal.

Reaching Climacteric Before Recovery from Injuries.—At the time of the trial of the personal injury case of Keefe vs. the Norfolk Suburban Street Railway Co., the plaintiff was 39 years and 11 months old, and contended that, if she should reach her climacteric before she had fully recovered, her suffering might be prolonged as one of the results of the accident. The company, on the other hand, contended that on the evidence the possibility that she would reach her climacteric before her full recovery from the accident was so remote that it should not be considered by the jury as an element of damage, and at the close of the evidence asked the court so to rule, which it declined to do, submitting this question to the jury. The Supreme Judicial Court of Massachusetts overrules an exception to this, holding that the whole question was one of fact for the jury, as, in view of all the evidence, it could not be said as a matter of law that the likelihood referred to was so remote as to call for the instruction requested by the company.

Letting Jury Know Physicians Were Appointed by Court.—Two of the errors complained of in the personal injury case of Stroh vs. the South Covington & Cincinnati Street Railway Co., consisted in the fact that the trial court permitted it to be known by the jury that the two physicians who testified in the case as to the extent of the plaintiff's injuries had been appointed by the court, and the misconduct of the attorney for the company in stating to the jury in his argument that these physicians had been appointed by the court. The Court of Appeals of Kentucky does not see how this could have prejudiced the plaintiff's case, who appealed on the ground that the damages awarded her were inadequate. It says that the doctors had been appointed by the court, under that large discretion which it possessed. The question was not material how they came to know the facts of which they deposed, but rather the truth of their evidence after they were on the stand. The plaintiff could not have been prejudiced by the knowledge on the part of the jury that these two witnesses came from an entirely impartial appointment. Nor does the Court of Appeals think that the plaintiff was prejudiced by the refusal of the trial court to permit her counsel to further cross-examine an expert witness after he had been thoroughly examined, and had told all he knew on the subject in hand. It says that any further cross-examination of him would be an unnecessary prolongation of the trial, which the court, in its wisdom, had the right to curtail. [See editorial this week.]

Province of Expert Witness.—The Supreme Court of Georgia says, in Travelers' Insurance Co. vs. Thornton, that under a prior decision it was left for the jury to say whether the insured's injury was caused by a fall and aggravated by hernia, or whether the hernia was a contributing cause to the injury. A physician could give an opinion on hypothetical facts on what he had heard other witnesses testify in the case, or on facts discovered by his own investigation. He could state what, in his opinion, would have been the effect of a blow to the insured without a hernia, and what the effect of the blow with the hernia. An expert can testify as to what was the cause of death, or of an injury, or as to the effect of disease, or as to the effect of a blow on one sound or on one unsound. He can give his opinion on physical facts or as to the medical facts, but he can not determine the legal classification of such facts. It was not proper for him to use the language of the decision and testify that the hernia was a "contributing cause." That was a mixed question of law and fact, to be determined in the light of all the evidence; and it would have been as improper to permit such testimony as it would have been in an ordinary case to allow a witness to say that a particular act amounted to negligence, or to contributory negligence, or that another fact was the proximate or remote cause. The expert may aid the jury, but he can not act as a member of the jury; nor, while on the stand, can he transcend the functions of a witness, and under the guise of giving testimony state a legal conclusion.

Examining Boards and Redress of Rejected Applicants—Evidence.—The Supreme Court of North Carolina says, in the case of Ewbank vs. Turner and others, that the power of the legislature to require examination and certificate as to the competency of persons desiring to practice professions or skilled trades is upheld, after a review of the authorities, in State vs. Call, 121 N. C. 643. That decision was reaffirmed in State vs. McKnight, 131 N. C. 717, the court calling attention to the fact that the state exercises this police power for the protection of the public from impostors and incompetents, and not to the end of conferring exclusive privileges on any particular body of men, for to do the latter is prohibited by the state constitution. It is a power to be exercised for the public good, and the legislature is to judge of the method of appointing the examiners, and can prescribe the nature of the examination, unless it appear plainly that the power to regulate is used in reality in violation of the guaranties in the constitution, and for the purpose of conferring exclusive privileges, and not solely for the protection of the public. State vs. Biggs (at this term), 46 S. E. Rep. 401; page 675 of The Journal, March

5, 1904. The code, the court goes on to say, provides for a board of examiners, to consist of six members of the North Carolina Dental Society, to be elected by said society. The presumption is that this honorable body will elect six of its ablest and most prominent members for the important duty of keeping up the standard of their profession by a just, reasonable and impartial examination of applicants. Should this important duty be neglected and incompetent or unworthy members be chosen, the remedy is by legislative repeal, or change of the method of selecting the board. Section 3151 provides that "said board shall grant a certificate of proficiency in the knowledge and practice of dentistry to all applicants who shall undergo a satisfactory examination, and who shall receive a majority of votes of said board on such proficiency." The lawmaking power having intrusted such examination to the board thus constituted, and required that the examination shall be satisfactory to them, and such requirements being reasonable and in violation of no constitutional provision, the courts can not intervene and direct the board to issue a certificate to one who the majority of the board have held has not passed a satisfactory examination, because, on the examination of experts, the court or jury might think the examination of the plaintiff ought to have been satisfactory to the board. That is a matter resting in the consciences and judgment of the board, under the provisions of the law, and the courts can not by a mandamus compel them to certify contrary to what they have declared to be the truth. Had the board refused to examine the applicant on his compliance with the regulations, the court could by mandamus compel them to examine him; but it can not compel them to issue him a certificate, when the preliminary qualification required by law, that the applicant shall be found proficient and competent by the examining board, is lacking. One remedy, if there should ever happen such abuse of trust as that the board "wrongfully, unlawfully, unjustly, arbitrarily, and without just cause or reason" declined to issue a license, would be, as already stated, by the legislature repealing the act, or providing a different method of selecting the board, or regulating the method or course of examination, or prescribing a review of the finding of the board by some other body, if the General Assembly should think proper. Another remedy would be to follow the precedent set by applicants for license to practice law, who, when rejected, study their prescribed course over again, and stand for examination at the next regular day. This is, perhaps, the most sensible course, for no man ever knows his profession too well. Another remedy still: If the applicant avers his rejection was caused by improper motives, his remedy is an action for damages against the individuals composing the board; alleging bad faith or arbitrary disregard of their duties, or improper animus against the plaintiff, or other malversation in their discharge of duty. In such action it might be difficult to prove the charges, unless by declarations made by the defendants themselves, for certainly the examination paper of the plaintiff himself would not be competent, in the first place, since, though experts might testify to its sufficiency in their judgment, that does not negative the good faith of the board, whose judgment, if exercised in good faith, is a protection to them. Malicious, illegal, or arbitrary action must be shown by direct evidence, and not by inference to be drawn by the jury from the fact that the opinion of witnesses introduced as experts may differ from the opinion of a legal board of examiners as to the sufficiency of the examination. It is only when there shall be other evidence first introduced, laying a sufficient ground for a charge of bad faith and misconduct, that the examination paper of the plaintiff could possibly be competent, and then only in corroboration of the evidence first introduced. And in no aspect could the papers of other applicants at the same time and place be put in evidence, for, even if they had been admitted to practice on insufficient answers, the plaintiff was not hurt thereby, and the introduction of irrelevant matter would only confuse the issue, which would be whether the plaintiff was refused a certificate, though he was shown to be qualified by his answers, by the arbitrariness, improper animus, and misconduct of the examining board.

1. **Abdominal Pain.**—Musser remarks that pain is a symptom which more than all others leads to the recognition and localization of abdominal disease, and it is fortunate when a patient is intelligent enough to describe it accurately. He first notices the associated expression of pain and spasm of the muscles, which is one of the most valuable indications. Its absence is of much significance under certain circumstances. It is wanting, of course, where there is little or no muscle, as in case of atrophied abdominal walls. In a case of perforating gastric ulcer with oncoming peritonitis operated on by Keen within six hours of perforation, no spasm or resistance was detected. Similar cases have occurred in cholecystitis where mural atrophy existed. The muscle spasm disappears with the onset of toxemia, and hence a rapidly lessening resistance is a matter of grave significance. Tenderness of the cutaneous surface, hyperalgesia, is also of importance; if it exists and then disappears, as may also spasm and pain, the change is of ill omen unless all the symptoms subside. The absence or the disappearance of hyperalgesia means gangrene or perhaps perforation. Passing over the subject of lead poisoning, Musser speaks of abdominal pain due to uremia, and reports a case showing its simulation of perforating gastric ulcer. He mentions hysteria and neuroses for the purpose of disclaiming against the accepted ideas of the frequency of abdominal pain of such origin. A number of conditions of abdominal pain not due to disease below the diaphragm are enumerated, such as the crises of locomotor ataxia and other organic spinal cord diseases, spondylitis rhizomelique, cancer and caries of the vertebra, aneurism of the thoracic aorta, diaphragmatic pleurisy and rheumatism of the diaphragm. Pneumonia may often produce abdominal pain, and he has been repeatedly called in to decide as to the necessity of abdominal operation when pneumonia existed. He also refers to cardiac affections, the epigastric pain of acute pericarditis and abdominal pain due to gastric affections. Epigastric hernia may give rise to symptoms simulating gastric affections or gall-bladder and gall-duct diseases. Hepatic and renal pain are also mentioned, and pancreatic pain. He believes that mild cases of pancreatitis are much more frequent than generally supposed. The disappearance of pain must not lead to any false security and we must look for the slightest suggestion of toxemia. A leucocyte count is often of great value. A low white count without improvement in symptoms and especially of the general toxemia symptoms, is of serious import. The absence of pain may be of value in the diagnosis, as, for example, in a case of intestinal paresis here reported.

2. **Abdominal Surgery.**—Wiggin's article is an elaborate one, with many illustrations, describing the method of suturing the appendix by the passing of three sutures across the site of the appendix before it is excised, subsequently tying them so that they are out of sight in the fold and supplementing them with four catgut Lembert sutures to complete the operation. He also describes his method of intestinal anastomosis, which consists in passing the sutures through the whole thickness of the bowel and tying them so that they are out of sight with the closure of the wound, making the last suture a Lembert. The sutures and knots are all left inside the gut except the last one. The technic is described in detail, as is also the after-treatment.

3. **Eye-Strain.**—Gould reports a case of torticollis and spinal curvature due to eye-strain and discusses other cases reported in the literature. The practical points he makes are that habitual abnormal position of the head, due to errors of refraction, is frequently the cause of spinal curvature. Heterophoria, which has been considered the cause, is usually secondary to refractive error, the proper correction of which, at an early age, cures the heterophoria, torticollis and spinal curvature.

15 *Some Clinical Features of Diseases of Gall Bladder and Bile Ducts Due to Gallstones, and the Indications for Their Surgical Treatment. Charles A. Elsberg.
16 Influence of Typhoid Fever on the Nervous System. C. C. Hersman.

7. **Cervical Lacerations.**—Dickinson points out the amount of trauma which the cervix receives during labor and the impossibility of proper repair of the injuries immediately after, at least in many cases. He would operate only between the third and fifteenth day, after the parts have become more normal and recognizable, unless the cervical laceration seems to be the cause of postpartum hemorrhage. His practice is to sew up all cervical tears in the first week in conjunction with the perineal operation when the pelvic floor injury is of such a character that a few days' delay is desirable, and to restore severe injuries to the cervix from the third to the tenth day after the delivery.

9. **Effects of Violet Rays on Nebulae.**—Herzog calls attention to the phenomena occurring when a nebula, as produced by one of the numerous nebulizers on the market, is passed around a vacuum electrode in action. As the current passes around the electrode it will be observed that the cloud of vapor develops with much greater rapidity and greater volume and that instead of falling to the floor or filling the middle portion of the room, it rises to the ceiling and floats around the room. The violet rays thus subdivide the vapor in such a manner as to cause it to be of much greater fineness. He thinks this fact may be of some importance since the finer the vapor the more readily are the medicaments which it carries absorbed by the respiratory organs.

10. **Primary Trachelorrhaphy.**—Donahue refers to a former article in which he advocated repair of the lacerated cervix within twenty-four to thirty-six hours after labor, and supports his former position by new arguments. He thinks the reaction, the disturbances due to the lacerated cervix, the possibility of the introduction of pathogenic germs, etc., call for early repair.

12. **Sodium Cinnamate in Tabes.**—Basing himself on the affinity of sodium cinnamate for nucleinic acid and the leucocytes, and its power of setting the current of the latter in the direction of any local exacerbation of the disease, Bartholow has employed sodium cinnamate injections in cases of tabes, so far with gratifying results. He has employed sodium cinnamate solution, 1 in 10 in sterile water, beginning with 20 minims and gradually raising the amount to 60 minims, hypodermically injected in the interscapular space. There was a decided gain in body weight and strength; some of the nervous phenomena diminished in severity and the co-ordination was improved. He thinks sodium cinnamate benefits the organism chiefly by promoting the appetite and digestion and consequently nutrition, but also by setting up chemical changes in the outlying regions of the degeneration in the cells and connective tissue of the nerve substance.

15. **Gall-Bladder Disease.**—Elsberg sums up the indications for operation as follows: It is contraindicated with mild symptoms, especially if the diagnosis is in doubt; with recurrent mild attacks with long intervals of health; in acute obstruction of the common bile duct, and in any disease which would contraindicate a surgical operation of any kind unless under vital indications. Operative treatment is indicated in acute inflammatory diseases of the gall bladder with signs of severe infection or peritoneal invasion. Also in cases with very frequent mild attacks, which incapacitate the patient from work, which are accompanied by much loss of flesh and strength, or in which the patient is in danger of acquiring the morphin habit. Also in case of a persistent biliary fistula, and in the rare cases in which the symptoms are due to adhesions of the normal gall bladder to neighboring organs. He thinks that in the future medical men will agree on more early and radical treatment and cholecystectomy will be more frequently performed.

17. **Pneumatic Tourniquets.**—The disadvantages of the ordinary tourniquet, the possibility of producing nerve-pressure paralysis, its painfulness and its interference with the best technic of the operation, are enumerated by Cushing, who then describes the pneumatic tourniquet. It was undoubtedly suggested by the use of the distensible armlet of the Riva-Rocci blood-pressure apparatus. A similar armlet, though broader and of less distensible rubber and capable of being boiled, was constructed. By connecting it with a bicycle pump one or two quick strokes of the piston is sufficient to fill it. He has used such an arrangement many times for cocain operations on the extremities, and with the greatest satisfaction. It can be adjusted and not inflated until the moment of beginning the operation. By palpating a peripheral artery one can easily tell when a sufficient degree of inflation has been reached. In operating in minor cases without assistants he has used a small bicycle foot pump. A larger and stronger form of cylinder than those which he has employed might be used for major operations on a muscular leg or thigh. He also mentions the therapeutic use of such apparatus for increasing venous congestion of the parts and improving the nutrition in certain chronic processes such as pseudarthroses, joint tuberculosis, etc. The especial application of the pneumatic tourniquet, however, to which he devotes most of his paper, is in cases in which the skull is opened for exploratory purposes, for which a wide osteoplastic flap is required. He has used a tourniquet of this pattern in 18 of his craniotomies during the past year. The method of opening the skull and making the osteoplastic flap is described in detail, with illustrations. The application of the tourniquet is also illustrated. He applies it over a large square of gauze. In order to prevent any possible rolling of the tourniquet after inflation in cases where the shape of the head is poorly adapted to secure it, the edge of the gauze hood may be drawn up over it, fore and aft, and pinned, or else a longitudinal tape may be used for the same purpose, as shown in one of his illustrations. The tourniquet is sufficiently narrow to lie well below the inferior areas of the motor zone. It is then inflated and a shovel-shaped incision of whatever form desired made through the gauze hood and scalp to the underlying bone. There may be a momentary bleeding as the imprisoned vessels of the scalp empty themselves, but it is only exceptionally necessary to clamp any bleeding points, and then only on the concave side of the incision where some of the veins may have diploetic communication. The convex side, which is the more important, remains dry. He thinks the use

of this inflatable tourniquet is not the least factor in simplifying the procedure of craniotomy, and the belief that such an apparatus has not been heretofore used is the ground for publishing this communication.

18. *Fecal Drowning.*—Goodman reports a case similar to those reported lately by Andrews. He explains them by the fact of ether destroying the sensibility of the throat. He considers the suggestion of Andrews as to the use of local anesthesia in intestinal obstruction a good one. His patient was apparently fully conscious at the time of the accident, though undoubtedly the throat was benumbed.

19. **Saliva.**—Hays' article reviews the physiologic chemistry and pathology of saliva, and concludes that there are many interesting points, some of which have only been worked out "in embryo." He thinks new methods of diagnosis are possible, and he is at present working on tuberculous saliva to determine some points. Another indication of just as profound value is in trying to detect urea in saliva in cases of eclampsia. Other possibilities will probably suggest themselves. We may find in the future that the examination of the saliva will play an important part in the diagnostic arsenal.

21. *X-Ray Therapy.*—Williams publishes a table to show the relative effect of different distances on the *x*-rays, based on the rule that applies to all forms of radiant energy, viz., that the intensity varies inversely as the square of the distance.

Distance.	Relative Intensity.			Safety limits.
2	1	1,000	25.00	2.5
4	1/4	.250	6.25	10.0
6	1/9	.111	2.77	22.5
8	1/16	.062	1.56	40.0
10	1/25	.040	1.00	62.5
12	1/36	.027	.69	90.0
14	1/49	.020	.51	122.5
16	1/64	.015	.39	160.0
18	1/81	.012	.30	202.5
20	1/100	.010	.25	250.0

In the first column are the distances at two inch intervals. In the second are the relative intensities expressed in fractions. In the third are the same expressed in decimals. In the fourth are the relative intensities expressed in decimals taking the intensity at ten inches as unity. This column is useful, since ten inches is the average distance for an exposure; when one wishes to estimate the total amount of treatment given he can by means of this column reduce the exposures which may have been given at various distances to their equivalent at ten inches and then add the number of minutes. In the fifth column are the safety limits or the duration of time which it is safe to expose a patient without danger of a dermatitis. These figures are the result of an experience of nearly two thousand exposures personally given and by experiments in bringing about a redness of the skin by a continuous exposure. The figures are about one-half of those required to produce a moderate degree of redness of the skin of the forearm with a tube of one ampère and fifteen volts with an equivalent spark-gap in the secondary circuit of five inches.

He found the column of safety limits a valuable guide in radiographic work. The knowledge that a dermatitis will be produced by approximately twice the duration of these exposures under conditions that he can regulate has been of great value in directing the treatment. Its application to deep growths requires especial attention as to time and distance. The further the part is from the tube the less is the difference between the effect on the skin and the part beneath. The exposure, therefore, should be more distant and the length of duration directly as the square of the distance. By referring to the table one can determine the duration of the exposure. His rule is not to expose in ten days more than the number of minutes required to produce a dermatitis. As this point is approached the exposures are shorter and at longer intervals in order to watch the developments. As soon as the redness is reached and its degree determined, the treatment can be continued and directed according to the indications. He thinks this method has a tendency to more rational technic based on physical laws.

22. See abstract in The Journal, xli, p. 1158.

23. **Pericarditis.**—The object of Paul's article, as stated by him, is to emphasize three points: 1, the insidious development of pericarditis, and how often it is overlooked unless particularly sought for; 2, that the severe type may develop in the course of a very mild pneumonia, and 3, the difficulty of distinguishing obliterative pericarditis from acute general tuberculosis involving the serous membranes. He gives the diagnosis and reports cases, and in conclusion calls attention to some of the more important signs of adherent chronic pericarditis as follows:

1. A systolic retraction in the region of the apex. 2. The sign described by Broudbent, which is a distinct systolic retraction of the chest wall in the region of the eleventh and twelfth ribs on the left side. 3. Friedreich's sign, a collapse of the cervical veins during diastole, and, according to Kussmaul, a swelling of the cervical veins during inspiration. 4. The pulsus paradoxus is significant of adherent pericarditis or rather of the dilatation which follows. The pulse becomes small and feeble during inspiration, due to traction on the adhesions during the inspiratory expansion of the lungs. As these bands are drawn on it causes a constriction of the vessels of the mediastinum; thus resulting in a small, feeble pulse wave during inspiration.

24. **Gastric Acidity.**—Benedict discusses the various methods of gastric analysis for acids and remarks that it makes comparatively little difference which of the several indicators is used, provided one understands that the results are approximate and reliable only for comparative purposes. With low hydrochloric acid and high fermentation, the readings of the burette are very inaccurate, although they indicate the therapeutic principles clearly enough. For accurate tests the chyme must be incinerated.

25. **Hydrotherapy.**—The various methods of hydrotherapy are noted by Baker, who gives the results of their employment in certain cases of mental disorder in the Morris Plains asylum. He has found the wet pack at 65 F., or the full bath at 95 to 105 F., very useful in excited cases and in insomnia, and at present has a case under treatment with mild excitement and confusion in which the wet pack seems almost to restore the normal condition. The improvement appears to be progressive. He has employed hydrotherapy in 26 cases of melancholia, with or without agitation, dementia precox, hysteria, puerperal insanity, characterized by depression and slowness of thought, painful delusions, etc., lack of nervous and muscle tone, sluggish circulation, anorexia, loss of weight, greasy, acne-covered skin, intestinal fermentation and constipation. In these cases he has used ablutions and wet packs with advantage, continuing for various periods according to the case, with decidedly good results, improvement in the physical condition, quieting of the agitation, gradual disappearance of delusions and of the prior mental state together with physical improvement. He thinks the methods valuable adjuncts to hygienic and medicinal measures.

26 *Blood-pressure Observations in Surgical Cases, Report of the Committee on Research for the Division of Surgery, Harvard Medical School, January, 1904. Wm. E. Faulkner, James S. Stone and Fred T. Murphy.

26. **Blood Pressure in Surgery.**—This, as its title indicates, is a composite article. The general results are summarized by the Committee on Surgical Research. Three questions were considered worthy of investigation: 1. Does the Riva-Rocci apparatus indicate the true blood pressure with sufficient accuracy for clinical purposes? 2. In what cases and under what circumstances are the errors due to the apparatus so great as to invalidate its advantageous use? 3. What is the value of blood-pressure observations under the following heads: *a*, as an indication for or against operation; *b*, during the course of an operation; *c*, in after-treatment of surgical cases? The first and second questions are discussed together and the summing up is given as follows:

1. The inaccurate readings obtained in cases of arteriosclerosis and excessive muscular development are partially obviated by the use of a 10 cm. armlet with the Riva-Rocci apparatus.

2. The presence of dyspnea causes inaccuracy in the blood-pressure determinations with either a broader or narrow band.

3. Change of posture invalidates the readings obtained with either form of apparatus.

4. Emotional individuals and children show fluctuations of the blood-pressure out of all relation to the actual condition of the patient.

5. Under other circumstances than those above recorded, the accuracy of the determinations with the Riva-Rocci apparatus appears to be sufficient for clinical purposes.

As regards the point *a* in the third question, the committee concluded that graphic determination of the blood pressure by means of the Riva-Rocci instrument may be an indication for or against the operation only after considering all the conditions which enter into the determination of blood pressure in any individual case, and like the symptom of leucocytosis, an estimate of the blood pressure may help to determine for or against operation in an individual case in connection with other symptoms. The cases in which it appears to offer the greatest promise are those in which the element of shock and of cerebral compression are present. As to its value in the course of operation, they remark that a change in the position of the patient is likely to cause a change of the blood pressure so great as to negative its value, and anesthesia may also affect it. The results of salt solution infusion and subcutaneous stimulation may be determined in some cases by means of the apparatus. Ordinarily, however, the condition of the patient as judged by the ordinary physical signs is better than blood-pressure reading on which to base an estimate of the physical condition. In the after-treatment of surgical cases, the number of observations made was comparatively few. They noticed a marked and rapid drop in the blood pressure shortly before death, occurring with equal regularity in cases of shock, fractures of the base, general peritonitis and sepsis. This "moribund drop" made its appearance at varying intervals before death, but in no case was there any doubt as to the prognosis from general physical signs. When recovery followed operation, except for the results of stimulation, no data of value in the after-treatment of the cases were obtained. The general conclusion is that the value of the Riva-Rocci apparatus in blood-pressure determination in surgical cases is limited to a small number of cases, chiefly those of cerebral compression and surgical shock. When these conditions are present and other confusing causes are eliminated, the value of the blood pressure as an indication for or against operation is increased. Under other circumstances the value of these observations is at present not apparent. They conclude that the use of blood-pressure tests as a routine practice is not necessary.

27 Histologic Structure of the Placenta. James W. Rowe.
28 *The Mechanics of Labor in a Peculiar Form of Dystocia. W. D. Porter.
29 Address of the Retiring President. Byron Stanton.
30 Address, Academy of Medicine of Cincinnati. S. P. Kramer.

28. **Peculiar Form of Dystocia.**—The special condition here described has been observed by Porter in about a dozen cases in the last ten years, and always in primiparæ. The condition may be described, he says, as follows: At an interval, varying from a few days to several weeks in advance of labor, the head is found well down in the pelvis. In some instances it almost rests on the pelvic floor. The cervical canal is obliterated and the lower uterine zone envelops the head. The external os can be felt like a dimple, firmly contracted. The uterine tissue surrounding the presenting part is so thin that the configuration of the head can be readily made out by the examining fingers. So thin is the tissue that sutures and fontanelles are easily outlined. The tyro might easily be deceived into believing that dilatation was complete, and that only the membrane separated his finger from the scalp. The condition of the cervix and lower zone is practically that which obtains in normal labor when it has advanced to the point at which the external os begins to dilate. The head occupies a much lower position than is usual at this point in labor. The condition, he thinks, is doubtless due to the necessity of economizing space. The firm abdominal walls force the fetus into the pelvis, and cause obliteration of the cervical canal and stretching and thinning the tissues of the lower zone. While it would appear that a speedy and easy labor should supervene, a tedious labor will almost certainly follow and the risks of bladder injury and septic infection are increased. The active factors in dilatation of the cervix are involved in peculiar difficulties. The lower uterine segment envelops the head, fitting snugly like a skull-cap, and this grasp is only accentuated by uterine contractions preventing distension of the membranes with water in advance of the head. The pains are nagging and ineffective. Artificial dilatation, he remarks, is the proper treatment. It should be employed early and is easy on account of the thinness of the cervical tissue, but this is apt to become caught between the head and the symphysis during the second stage. It can be pushed up, but descends again. The whole of the uterus is too low and unusual care is necessary to prevent tearing. The low position of the uterus also insures an abnormally low position of the bladder, exposing it to increased danger of trauma, and care should be taken to keep the bladder practically empty. In case the second stage is very difficult, considerable bruising of the bladder wall is inevitable.

37 *Value of Total and Differential Leucocyte Counts During the Course of Typhoid Fever. Henry A. Higley.
38 *A New Sign of Basilar Meningitis. G. W. Squires.

33. **Iodid of Potassium in Pneumonia.**—Altshul claims that he has not had a death in twelve years out of 62 cases of pneumonia treated with iodid of potassium, and thinks that the action of the drug is directly antagonistic to the disease. The method of treatment is to give an initial dose of at least 10 to 15 grains, increasing it by 5 to 10 grains every two or three hours day and night, according to the severity of the case, until defervescence is well established. However soft the pulse may become the dose is kept up, the guide being the regularity of the heart, as determined not by the pulse alone, but by auscultation of the heart itself and the character of the heart sounds, especially the second pulmonic. If this be clear and distinct, we are accomplishing what is desired. If there is irregularity in the heart itself, strychnin in the dose of 1/60 to 1/40 gr. every four or six hours is given until the heart becomes regular. In this manner he has in a large number of cases given 1,000 to 1,500 grains of the iodid in a 50 per cent. solution, in milk, per day, and in one case as high as 1,800 grains. Dr. H. T. Prentiss of Holyoke, Mass., reported to him a case in which he gave 3,000 grains daily for about four days, and to another patient, a child, he gave 2,100 grains daily for two days with no signs of intolerance, and recovery in both cases. At the commencement there may be a slight coryza, but this disappears as the dose is increased. He insists on the importance of the condition of the heart during this treatment, and believes that failures are due to faulty methods and lack of courage.

36. **Tropical Hygiene.**—Guthrie thinks that there is too much germophobia in the tropics and that the microscope may be over-used. The sun's rays exert more influence in the Philippines than in any other tropical country, because the whites there have not yet learned to accommodate themselves to their environment. They do not dress properly nor bathe sufficiently to keep the skin in good order. Besides the sun's rays there are other agencies such as insects in choice assortments; there is in reserve an array of living things to prey upon the poor alien's depleted cuticle. Insects not only expend their poisons through stings, but there is another easy avenue, that is, the vile habit of "tuba" drinking. Tuba is obtained by tapping the blossom stalk of the cocoanut tree, allowing the sap to drop into a joint of bamboo for days. In the meanwhile every kind of insect gets into it. Though they may be drained out afterwards, there remains in liquid form a strong essence of bug. This, he thinks, is the main reason why it is so poisonous. Another alcoholic poison is "bino," against which he warns Americans. This may be any kind of doctored fluid, but is very apt to contain wood alcohol. It may safely be said that alcohol is not a necessity in any part of the tropics, but if one is addicted to it, he should confine himself to the best that is to be had, and should never drink before the midday meal. In fact, drinking should be regulated by a competent physician in any case. To live properly, dieting one's'f, keeping down the deposit of uric acid with plain food is best.

Rest between the hours of 11 and 3 is essential, avoiding the sun, keeping the body cool by frequent bathing; lemon and lime juice in water is much more wholesome than alcohol. When the tissues become lax, as shown in many cases of dilatation of the stomach and dropsical effusion of the lower limbs, it is time to take two or three months' vacation and go to a cooler climate. The wearing of a flannel band day and night is not a necessity but a habit. He thinks, however, that the abdomen should be protected while sleeping. The water supply is the one thing where care is imperative, the drinking of distilled water if possible, and having the clothing washed in the same, or boiled. He advises against eating food handled by natives, not that he wishes to criticise the Filipinos' personal habits, but that he thinks their hands are not microscopically clean. Americans there should disinfect their hands by occasional ablution in a 0.1 per cent. solution of bichlorid, and be warned against the practice of scratching, keeping the hands away from the face and hair as much as possible. Scrupulous care of the teeth is another important matter, and afterwards he would rinse the mouth and gargle the throat with warm Dobell's solution, allowing some of the warm solution to be snuffed up and flow past the posterior nares without swallowing. By adopting these habits of microscopic cleanliness, he thinks that the chances of contracting disease would be reduced to a minimum. He remarks in conclusion that Americans are beginning to learn how to live in the Philippines and he is pleased to observe it. He suggests that his plan of cooling buildings with refrigerating stoves be tried if only as an experiment.

37. **Leucocytosis in Typhoid.**—The characteristic typhoid leucocytosis, such as reduction in the total number with a relative increase of large mononuclears and a relative decrease of polymorphonuclears should be watched, Higley thinks, in this disease. So long as the typhoid infection remains pure the characteristics of the total and differential leucocyte counts peculiar to this disease are maintained, but they are altered in case of complicating infections. Therefore, frequent and careful, total and differential leucocyte counts may be of great value in enabling the physician to keep in touch with the variations in any given case.

38. **New Sign of Basilar Meningitis.**—The sign which Squires has found to be invariably present in this disease, frequently as early as the fourth or fifth day, according to the severity of the attack, is a rhythmical dilatation and contraction of the pupil. The method of obtaining the sign is as follows:

> Place the child's head between the knees of the physician, face upward, with the body of the child supported *on the bed, table, or* lap of the nurse. Grasp the sides of the child's head with each hand and produce gradual and forcible extension of the head on the spinal column. As the head is *brought* back in this extension the pupils will be seen to commence to dilate simultaneously with the commencement of extension, the more extreme the extension the more the dilatation. *Now on* flexion the pupils contract so that when the chin is forcibly brought to the manubrium the pupils are well closed up. This can be done several times a minute, and each time the pupillary phenomenon will be repeated. The dilated pupils, with extreme retraction of the head in the late stages of the disease, may be in some measure mechanical or hydrostatic *from increased* pressure by effusion on the nerve roots or centers at the base of the brain. An early recognition and treatment of this disease is very important, if we would hope to save many of our little patients.

39 *Physical and Chemical Forces in Vital Operations. Charles F. Dight.
40 Some Local [illegible] J. Clark Stewart.
41 *A Note on [illegible] esthesia for Short Operations—Pleasant, [illegible] Edward J. Brown.

39. **Vitality.**—Dight concludes *that aside* from the processes by which the living cells build lifeless food material up into living protoplasm *and the facts of* reproduction, the physical and chemical forces explain the vital phenomena. The difference, *however, between* living and dead matter is so far unbridged, and *the* possibilities of germ cells can not be explained by chemistry.

41. **Primary Ether Anesthesia.**—Brown has used primary ether anesthesia in operations *on* the throat and nose since last June in 21 different patients, mostly young children. He administered the ether by the drop method with the ordinary chloroform mask, using from 8 to 10 grams in from one and a half to two minutes; in most cases following one or two applications of 20 per cent. cocain. In a few of the later cases, including the removal of adenoids in four-year old twins in his own family, the cocain was omitted without apparent disadvantage. He finds that children take ether without objection, breathing deeply with the mouth open, and vomiting has not occurred nor undue hemorrhage. He considers the method pleasant, safe and efficient.

42. **Perineal Zoster.**—Cushing reports two cases from which, as a text, he discusses the general subject of nerve distribution from the lower portion of the cord and its termination. The article is not capable of being abstracted in sufficient detail to do it justice, and would also require the reproduction of many of the illustrations.

43. **Typhoid Fever.**—Thayer's conclusions, in brief, from a study of 183 cases of individuals who have had typhoid, are as follows: 1. The average systolic blood pressure in these old typhoids was appreciably higher than in the control observations of healthy individuals. 2. The higher average of the blood pressure was constant in every decade. 3. In many instances *among them the blood pressure* exceeded appreciably the limits ordinarily expected. 4. The radial arteries were palpable in a proportion nearly three times as great as was found to be the case in supposedly healthy individuals who had never had the disease. 5. The average size of the heart was greater than at the time of their first appearance at the Johns Hopkins Hospital, with typhoid fever. 6. Cardiac murmurs were considerably more frequent among old typhoids and in the same cases during attacks. 7. In 8 cases where the heart was considered normal on discharge from the hospital, subsequent examination revealed hypertrophy with mitral insufficiency. One case showed a possible mitral stenosis, one aortic insufficiency, one general arteriosclerosis *with hypertension.* 8. *In one case the aortic diastolic murmur* was present four months after discharge, but disappeared later. 9. *Patients* whose pulse was very irregular during the disease showed on the average a higher blood pressure than others. In other respects their condition was very little different. 10. In cases where the systolic murmur at the apex was observed during the attack, showed later an increase in the blood pressure and in the size of the heart, as compared both with the mean of observations made on the same cases on admission and with the general average for the old *typhoids.* Nearly one-quarter of the cases in which during the attack systolic apical murmurs were detected, showed later evidence of organic heart disease. Indeed the majority of all the organic lesions *among the* 183 old typhoids were found among these 31 cases. Thayer remarks that these figures are not as adequate as a larger series would be, but he thinks that they

indicate that the disease is an active factor in the etiology of a considerable number of heart lesions later in life.

46. **Bursae of the Neck.**—The history of these formations is reviewed by Anderson, as are also their symptoms. The cases he has observed were in females, but he thinks their sensitiveness to the deformity may be the cause of their having revealed it. Both cases are reported in detail, and others from the literature are briefly abstracted. As regards treatment he remarks that there is little hope from internal medication. The local use of absorbents or irritants seldom does good. Sometimes, as in one case reported by the author, the cyst disappeared without treatment. No irritating local applications should be used as fistula has followed such. Simple incision with drainage is of no value; if it closes, recurrence follows; if it remains open, fistula is produced. Drainage of the sac and use of local absorbents to produce closure has been tried successfully in some cases. Failures are also reported, and in some with a chronic suppurating fistula as the result. When it is recalled that the sac normally extends up beyond the hyoid bone, narrowing as it ascends, and is usually prolonged downward to an infundibuliform prolongation, it is easy to understand why it can not be readily obliterated. Incision and cauterization have been tried and good results reported. Solutions of iodin, carbolic acid, etc., to excite inflammation have been used with varying results. Panus cured a case by the injection of chlorid of zinc solution into the sac without evacuation. Partial extirpation of the cyst is unsatisfactory and not advisable. Complete extirpation of the cyst is by far the most satisfactory method. Difficulty has often been experienced in dissecting it out entirely. Weir's method of injecting the sac with melted paraffin and allowing it to harden before dissection is an excellent method, and allows the cyst to be shelled out entire.

47. **Hemolymph Nodes.**—From a study of the subject and experimental work Dayton concludes that both histologic and experimental evidence indicate the existence of hemolymph nodes as organs *sui generis.* The chief practical point is to recognize the capability for phagocytic destruction of red blood cells which is possessed to a high degree by certain lymph structures, rather than to dwell on the individuality of the hemolymph node. The occurrence of transition forms from the node containing blood sinuses only to that with sinuses containing only hemolymph, renders a strict classification impossible. For practical purposes Warthin's grouping of all varieties under the heading of hemolymph nodes seems satisfactory.

49. **Premature Infants.**—Morse has studied the subjects of the caloric needs of prematurely born children, ~~and illustrates~~ his paper with diagrams ~~and temperature curves~~. The conclusion which he reaches is that the caloric need of premature infants is relatively greater than that of full-term children. In part this is due to the small size and the comparatively large surface area of premature infants, from which they lose heat faster than do the full-term children, and partially to the incomplete development of their digestive power, utilizing a smaller portion of caloric value of the food. He emphasizes the importance of protecting premature infants against loss of heat and providing for them food which shall throw the least work on their imperfectly developed digestive organs.

50. **Eosinophiles in Parasitic Infection.**—Opie has experimented on guinea-pigs with an injection of *Trichina spiralis*, and finds that it causes an increase of eosinophiles in the blood comparable to that which accompanies human infection. There is no constant alteration in the number of cells until the end of the second week after the infection, when their relative and absolute number rapidly increases and reaches a maximum at the end of the third week. At this time embryonic trichinæ are being transmitted from the intestinal mucosa by way of the lymph vessels and blood through the lungs to the muscles. Eosinophile cells accumulate in the mesenteric lymph glands and lungs, forming foci which resemble small abscesses in which polynuclear leucocytes are replaced by eosinophile cells. There are also characteristic changes in the bone marrow. The fat is diminished and cellular elements replace it, and the eosinophiles are present in immense number. The eosinophile myelocytes peculiar to the bone marrow are especially numerous; the number of eosinophile leucocytes in the blood always diminishes before death so that the proportion usually becomes less than 1 per cent. Infection with a very large number of trichinæ causes a rapid diminution of the number of eosinophile leucocytes and is quickly fatal. Mild infection stimulates them to active multiplication, but severe infection causes their destruction.

Critic and Guide, New York.

March.

56 *What Can We Accomplish in Cases of Laryngeal Tuberculosis? W. Freudenthal.
57 *The Relation of the General Practitioner to Eye-strain in His Patients. S. Solis-Cohen.

56. **Laryngeal Tuberculosis.**—Freudenthal remarks in regard to his having previously called attention to a pre-tuberculous laryngitis, which may be either anemic or hyperemic. In the anemic stage he uses insufflations of zinc-sozoiodol with sugar-of-milk, 3 per cent. nitrate of silver applications, liquor ferri sesquichlor (1 to 30), and balsam of Peru. He avoids astringents and caustics as they might produce more effects than desired. In the hyperemic stage he has had good results with a solution of 5 parts creosote; spirits of wine, 10, and glycerin, 50. Applications of tannin, alum and other astringents have been used with benefit. Once laryngeal tuberculosis is established the prognosis is considered absolutely bad by some, but with this he disagrees. He has seen some cases recover, and this depends on the character of the pulmonary trouble. If there are simple infiltrations with no symptoms but hoarseness, the best plan is to treat the pulmonary disease and leave the larynx alone, but if the tissue is broken down and ulcerations appear, two drugs have given him special satisfaction: the first is anesthesin (Ritsert), and the second orthoform. With ulcerations or denuded surfaces he gives the patient 1.5 to 3 grains of anesthesin, or even more with sugar, several times daily, without any water. They often give the patient great relief. In most cases, however, topical applications are necessary, and he has used orthoform, pure or in emulsion, with menthol, which goes under the name of Freudenthal's emulsion, and is an excellent anodyne when we can reach the ulcer. Astringents may be combined with the orthoform. In cases of ulcers he has found lubricating the esophagus with oil before the taking of food of value. He has given olive oil for the purpose, but its taste is an objection. The last year or so he has used as a curative measure high frequency currents, applying a curved electrode directly to the larynx. The application is not difficult or dangerous, and not even unpleasant if one is careful. He will publish his experience with this method more fully in another place.

57. **Eye-Strain.**—Solis-Cohen calls attention to the importance of eye-strain, and especially to the work of Gould in this regard.

62 *Formation and Resolution of Peritoneal Adhesions and Exudates. Horace G. Wetherell.

62. **Peritoneal Adhesions.**—Wetherell concludes from his study of cases that peritoneal adhesions and exudates are essentially conservative, and that with rare exceptions when the source of irritation or infection which causes them is removed, they will be taken up and disposed of. That tympanites,

through increasing the intra-abdominal pressure without peristalsis, and even so-called intestinal paralysis are means to the same conservative end. We should avoid combating these during the acute stage of disease by untimely operation or the giving of food or cathartics. That ordinarily an interval operation will be required for the removal of the source of infection in order to restore the patient to health and insure immunity from relapses; such an operation in skilled hands is many times safer than the let-alone policy. Of course, this does not apply to severe peritoneal infection of perforative origin, for which prompt operation is required.

66 *Ventrofixation of the Uterus with Subsequent Normal Deliveries. A. Lapthorn Smith.
67 A Medical Medley. J. S. Sprague.
68 Report of a Case of Scald. Everett S. Hicks.

66. **Ventrofixation.**—Smith believes that the evil effects of ventrofixations in subsequent pregnancy are due to the faulty manner in which they have been performed, namely, the uterus being put upside down forward, and fastened there with its back to the abdominal wall, so that the cervix pointed toward the liver. Properly, the anterior surface of the fundus should be scarified and attached to the abdominal wall just above the pubis. If this were invariably done we should hear no more of abnormal labors after ventrofixation. He has performed the operation nearly 250 times, and with almost invariably satisfactory results.

74 Extra-uterine Pregnancy. John P. Lord.

69. **Chloroform.**—Henry has had an unfortunate case of death from chloroform in a patient on whom he was about to perform a uterine operation. He reviews the subject and opinions, and concludes that chloroform is a dangerous anesthetic, much more so than ether; except in serious lung and kidney trouble, chloroform should not be given unless ether and A. C. E. mixture are contraindicated. He says all hospitals should be provided with nitrous oxid gas for short operations or to precede the ether, and the latter should be administered by the drop method.

73. **Exophthalmic Goiter.**—Crummer reports two cases, and thinks we can conclude from them as to the danger of the use of iodin in simple goiter, and, further, that there is reasonable hope of aid in the use of the antithyroid specific form of treatment in exophthalmic goiter. Every case of persistent rapid heart, especially in women and young girls, should be considered as possibly due to Graves' disease and be properly treated. One of his patients was put on the Lanz treatment, taking the milk of dethyroidized goats, and was greatly benefited. (See abstract of Lanz's article in The Journal, xl, p. 689.)

75.—This article has appeared elsewhere. See The Journal of January 9, ¶61, p. 128.

77. **Hare-Lip Operations.**—The important points in hare-lip operations, as enumerated by Putnam, are as follows: To cleanse the nostrils carefully with boric acid and sterile water, also the lips and mouth. Etherize the patient but lightly, so that the coughing reflex will prevent blood inhalation. Free the lips and cheeks thoroughly so as to take all tension from the intended line of sutures. Control the coronary arteries with the fingers; cut flaps; put stitches in the mucous membrane, to be tied later; put "principal" suture well back from the edges of the wound, and do not tie it too tightly. Approximate the edges carefully with superficial sutures; wash out the stomach for blood and dry the wound and dust with aristol. In case of double hare-lip he would advise against immediate nursing as the result is always somewhat injured by the procedure.

78. **Speech Defects.**—In considering the cause of speech defects ~~we~~ should note how far they are the result of disease or mal-development in the mouth, nose and pharynx and nasal cavity from chronic catarrh, or ~~in the worst cases~~ by adenoids. The nasal obstruction, if considerable, interferes with the escape of air through the nose in articulating the letters M and N, and so on. The most important defects in the mouth cavity ~~is~~ a deficient or cleft palate, b~~ut we have~~ others such as tongue-tie, large tongue, long tongue, thick tongue, etc. In ~~certain Mongolian idiots and cretins enlarged tongue exists, but it is doubtful whether it has much to do with the delay in speech.~~ Tongue-tie is not very important. If the child can protrude its tongue so that the tip passes over the lower lip and can pronounce words beginning with L, its tongue is free enough. The V-shaped palates have been regarded as the cause of defective speech. They are often associated with more or less nasal obstruction, the posterior openings being narrow or blocked with adenoids. There are some few cases where the high palate is associated with speech suggesting cleft palate, indistinct and of a nasal twang. ~~He thinks it would not be surprising to find that it had some effect when we consider how much trouble children operated on for cleft palate experience in acquiring normal speech.~~ Possibly in such cases the soft palate acts imperfectly in shutting off the cavity of the pharynx from the nasal cavity, but it is more likely to be an imperfect innervation than a speech defect. The two most important questions in examining a child who fails to talk at three years or over is, first, is the child deaf; second, what is its mental status as compared with other children of the same age. Oral deformities are hardly likely to explain failure to talk, though long-continued ill health or some recent illness will have to be considered. The detection of deafness is not always easy, and parents are constantly deceived. A child may hear loud noises and yet be unable to distinguish words. As the child becomes older and more intelligent the difficulty is less. Some feeble-minded or abnormal children will absolutely refuse to answer questions, though it is clear that they hear the sound. In other abnormal children the attention is defective. Cases of so-called congenital aphasia are not altogether rare, though such children are not often of normal intelligence. It is rare, ~~Ashby thinks~~, that some defect or mental feebleness does not accompany the failure to talk. The chief defects met with in ordinary children are articulation defects varying from the mispronunciation of a few consonants to an almost unintelligible mumble. Th~~e term "lalling" is sometimes used to include these defects.~~ Marked lalling in children of six years or more is nearly always associated with some subnormal intellectual power, though the latter may be present without any speech defects whatever. ~~He notices~~ the development of infants, and calls attention to the fact that defective children are generally clumsy in other movements, as in swallowing. The first thing in the treatment is to test the ~~hearing, examine the mouth, nose and throat~~, and estimate the

~~child's mental~~ powers. Often the nature of the defect of articulation may be decided by means of the physiologic alphabet, using the names of common objects familiar to the child, besides scamping and transposing consonants. A thick, indistinct utterance is very common, and whispering is not uncommon. Breathing exercises, he thinks, are of much value in conjunction with other physical exercises in these cases. Singing or vocal exercises of the larynx are likely to be useful. Much will depend, of course, on the child's intelligence and perseverance.

79. Whooping Cough.—The statistics of whooping cough, as based on the mortality returns in the principal cities and elsewhere, are noticed by Root, who points out that whooping cough is as much to be dreaded as a fatal disease as scarlet fever, and may not leave the patient in as good a condition as before. Sometimes severe disturbances of the nervous system remain. She believes that whooping cough should be under the control of the authorities and subject to quarantine as much as scarlet fever. It is less individually contagious, is not carried by one patient to another as far as known, and its control need not be as complicated and far-reaching as that of scarlet fever, but it is imperative, she holds, that whooping cough should be isolated and controlled.

1. The Treatment of Serous Effusions.—Barr had a patient who suffered from hydrothorax with cancerous conditions and effusion rapidly reproducing itself, requiring repeated tappings. In order to make life more endurable, he thought it would be well to try the use of adrenalin to lessen the amount of effusion, and after the fifth aspiration, which took place four days after the preceding one, a dram of a 1 in 1,000 solution of adrenalin chlorid was injected. There was no further secretion, and the old lady spent the rest of her life in comfort as far as her chest was concerned. Since then he has used it in a fair number of cases of pleurisy with effusion, invariably with success, using one dram on each occasion. He has since extended this treatment to ascites. The first cases were of hepatic cirrhosis with obstruction, and while the results were not striking, the patients showed no ill effects. In one case some slight collapse was noticed after the injection, but he does not credit it to the adrenalin. Collapse after tapping ascites is not an uncommon event. The next use of the remedy was in a case of pericarditis where 40 minims were injected into the pericardium, with the result of nearly cutting off the circulation of the heart, but the condition was quickly relieved by the injection of 3 minims of a 1 per cent. solution of nitroglycerin and 2 of aqua atrop. sulph. No further tapping was needed. It was evident that in this case the dose was rather too large. Later in the same case a pleural effusion was treated similarly, and it occurred to Barr that in addition to the tapping, if he substituted another fluid, say air, for that which was withdrawn, he might prevent subsequent adhesions. With this object he injected half a pint of sterile air, and it was not all absorbed for at least ten days. He thinks the adhesions were lessened by the injection. Another case of ascites is reported treated by injection of 2 drams of adrenalin chlorid, with the best results, the ascites being apparently completely checked, and four pints of aseptic air were introduced with the adrenalin e describes the apparatus which he has devised for of air and adrenalin, consisting essentially of a s bottle, with three openings at the top and an bottom, each guarded by a glass stopcock. One in connection with the water reservoir, the second is with a large thistle head filled with cotton wool for filtering the air, the third is the outlet for the aseptic air to be driven into the pleural or peritoneal cavity by allowing the n in through the reservoir. This apparatus was ersome, and he has substituted for it a little inich a German veterinary surgeon uses for introıseptic air into the udders of cows, fitting a small c pump to the apparatus, consisting of a trochar canula with two arms and a siphon tube, a syringe for injecting the adrenalin and an apparatus for introducing the filtered air. The whole can be boiled, with the exception of the cotton wool filter, and it can be sterilized by heat as often as is necessary. A detailed summary of some of the cases is given. He remarks that the treatment is easily carried out and the apparatus is fairly perfect, but aseptic precautions are necessary. He objects to the use of pure oxygen instead of air, holding that it would be absorbed too quickly, and the injection of air has an advantage in that it prevents collateral hyperemia and edema of the other lung, which sometimes follows the withdrawal of large quantities of fluid.

5. Nasal and Nasopharyngeal Disease.—Syme calls attention to the conditions which may follow these local disorders. He thinks it is advisable in cases of chronic illness associated or not with gastric derangement, to include among the possible causes certain affections of the nose and nasopharynx, especially where the discharge is of a mucopurulent or purulent character. Nasal affections, he thinks, in these instances may be possible contributory causes. It is probably some physical weakness which makes the patient more liable to the evil effects of the introduction of purulent matter into the stomach. The nasal treatment, therefore, while necessary, must be looked on as a reinforcement of, rather than an alternative to, other methods.

7. The Pneumococcus.—Gordon points out and illustrates the formation of capsule around the pneumococcus in gelatin cultures at 37 C., and thinks that its property of forming such in one day may be applied to the identification of the microorganisms and their differentiation from the specimens of *Streptococcus pyogenes*.

9. Pancreatic Disease.—Robson points out the possibilities of gastric ulcer being associated with disease of the pancreas and invading it by new growth, and changes in the anatomy of the ducts as bearing on the question of producing jaundice and pancreatic disorder. He describes the anatomy of the pancreas, and goes at length into the special symptoms of its disease: the digestive, including steatorrhea and azotorrhea or faulty digestion of albuminous foods, excessive secretion, greasy, pale diarrhea, dyspepsia, alteration of the appetite, emaciation, nausea and vomiting. Among the physical signs are tumor, fever, pain and tenderness, pressure symptoms, such as ascites, owing to the involvement of the portal vein, hemorrhage and jaundice. The metabolic symptoms include diabetes and glycosuria with other changes in the urine, such as indicanuria, though observations show the amount of indican is no guide to the presence or absence of disease. Pentosuria is of greater diagnostic importance. He thinks certain reactions may be obtained from the urine in the greater number of if not in all cases of pancreatic disease, which are a material help in the diagnosis. He thinks it is possible to distinguish between acute and chronic inflammation, simple and malignant disease. Glycosuria does not interfere, but the sugar has first to be removed by fermentation. In this article he does not describe the reaction, but it is given later by Cammidge. Alimentary glycosuria occurring from a partially disordered affection of the pancreas is of some value in the diagnosis and Sahli's symptom of giving iodoform in a capsule hardened by formalin and testing the urine for iodin is also mentioned, and some remarks are made in regard to fat necrosis and hemorrhage. As regards the former, he thinks his cases disprove the statement that it is necessarily of fatal significance. Hemorrhage may be due to vascular disease, injury, fatty degeneration of the gland cells in alcoholism, necrosis in the glands, disintegration of neoplasms, embolism of a pancreatic artery and other causes such as heart and lung disease, hepatic cirrhosis, hemorrhagic diathesis, scurvy, phosphorus poisoning, etc. Pancreatitis may undoubtedly lead to hemorrhage and the symptoms may vary from colic to violent and persistent pain followed by collapse and death. The site of the pain may be precordial or dorsal, but it is usually epigastric. The diagnosis may be obscured at first, but with the onset of pancreatitis some of the symptoms mentioned will be present and the pancreatic reaction in the urine will offer a valuable help. In all the stages the treatment is that of acute pancreatitis.

10. Pancreatic Reaction.—In this lecture Cammidge gives the pancreatic reaction mentioned above by Robson. He describes the procedure in which he calls reaction "A" as follows:

> The specimen of urine to be examined is filtered, and 10 c.c. of the filtrate are poured into a small flask. One cubic centimeter of strong hydrochloric acid is added and a funnel having been placed in the neck to act as a condenser the flask is placed on a sand bath and gently boiled for ten minutes after the first sign of ebullition is detected. A mixture of 5 c.c. of the filtered urine and 5 c.c. of distilled water is then poured into the flask, which is afterwards cooled in running water. The excess of acid is now neutralized by slowly adding 4 grams of lead carbonate and, after standing for a few minutes to allow of the completion of the reaction, the urine is filtered through a moistened filter paper and the flask is washed out with 5 c.c. of distilled water on to the filter. To the clear filtrate are now added 2 grams of powdered sodium acetate and 0.75 gram of phenylhydrazin hydrochlorate and the mixture is boiled for from three to four minutes on the sand bath. The hot fluid is then poured into a test tube and allowed to cool undisturbed. After the lapse of a period, varying with the

severity of the case from one to 24 hours, a more or less abundant flocculent yellow deposit is found at the bottom of the tube, and this when examined under the microscope with a 1/6-inch objective is seen to consist of sheaves and rosettes of golden yellow crystals. As the presence of sugar in the urine would obviously vitiate the results thus obtained it is necessary before proceeding to the test to make sure that the untreated urine does not give a reaction wih phenylhydrazin. This may roughly be done with Fehling's solution, or some similar test, but it is better to carry out a control experiment with phenylhydrazin hydrochlorate and sodium acetate in the manner I have just described, omitting the preliminary boiling with hydrochloric acid. Should the control experiment reveal even a trace of sugar it must be removed by fermentation, with subsequent boiling to expel the alcohol formed, before the investigation is proceeded with. The presence of albumin in the urine is also liable to cause trouble, and it is best got rid of either by treatment with ammonium sulphate or by acidifying with acetic acid, heating and filtering. The results obtained by this method were found not to be absolutely trustworthy, although a useful aid in diagnosis, since a positive reaction was also obtained in patients suffering from certain other diseases where active tissue change was taking place, such as cancer, adenitis, pneumonia, etc. For a long time the positive reaction given by these non-pancreatic cases diminished the practical usefulness of the test, but eventually a means by which the cases of pancreatitis might be distinguished was devised, and we now believe that by combining the results of the two, it is possible in the large majority of cases to make a trustworthy diagnosis from the examination of the urine alone. The differentiating test depends on the fact that the formation of the crystals described in reaction "A" is interfered with in inflammation of the pancreas by a preliminary treatment of the urine with perchlorid of mercury, while such treatment does not affect the appearance of crystals in cases of cancer of the pancreas and the other conditions which give rise to a positive reaction. The procedure, which I shall refer to as the "B" reaction, is as follows: Twenty c.c. of the filtered urine are thoroughly mixed with half its bulk of a saturated solution of perchlorid of mercury. After standing for a few minutes it is carefully filtered and to 10 c.c. of the filtrate 1 c.c. of strong hydrochloric acid is added. The mixture is then boiled for ten minutes on a sand bath and subsequently diluted with 5 c.c. of the filtrate from the mixed urine and perchlorid of mercury solution and 10 c.c. of distilled water. After cooling it is neutralized with 4 grams of lead carbonate and the succeeding stages of the operation are carried out as in reaction "A."

Experiments were then set on foot to still further differentiate the forms of disease, and a careful observation of the crystals isolated from the urines of various types of pancreatic disease showed that while there is a general resemblance, certain variations occurred and the differing rate of solubility of crystals in dilute sulphuric acid was remarked and found to be of still greater value. If the crystals obtained in reaction "A" are observed under the microscope while a 1 in 3 dilution of sulphuric acid is being irrigated under the cover glass, they will be seen to turn brown when the acid reaches them and dissolve. In acute pancreatitis the interval that elapses between the first appearance of the brown color and complete solution varies from a few seconds to half or three-quarters of a minute. In chronic pancreatitis it extends from half to one and a half or rarely to two minutes, while in malignant disease the crystals do not completely disappear until three to six minutes. The practical results of the examination of the urine he summarizes as follows:

1. If no crystals are found by either the "A" or "B" method the pancreas is not at fault and some other explanation of the symptoms ought to be sought. 2. If crystals are obtained by the "A" method, but not by the "B" reaction, active inflammation of the pancreas is present and surgical interference is generally indicated. (*a*) The crystals obtained by the "A" method will in acute inflammation dissolve in 33 per cent. sulphuric acid in about half a minute. (*b*) In chronic inflammation the crystals obtained by the "A" method will take one or two minutes to disappear. 3. If crystals are found in preparations made by both the "A" and the "B" methods there may be (*a*) malignant disease of the pancreas, when the crystals will, as a rule, take from three to five minutes to dissolve and operation is inadvisable; (*b*) a damaged pancreas due to past pancreatitis, when the crystals will dissolve in from one to two minutes; (*c*) some disease not connected with the pancreas, when the crystals dissolve in about one minute. In the two latter (*b*) and (*c*), the urgency of the symptoms and the condition of the patient must decide the need for an exploratory incision, but there is generally not much difficulty in referring the case to one or other of the groups when the clinical history is considered in conjunction with the result of the examination of the urine.

The microscopic examination of centrifugalized deposit of the urine is also of some use, and he describes the different forms of deposits that are observed, and in the conclusion of his lecture mentions the different observations in the reaction and the dissolving of crystals in more detail.

14. Report of the French Yellow Fever Commission.—This commission was sent to Brazil by the French government in 1901 and remained there for two years, studying yellow fever with every facility afforded by the Brazilian authorities. Among the conclusions announced as the results of this research is one to the effect that the serum of a yellow fever subject is virulent for three days, but by the fourth day there is no longer any virus to be found in it, even when the fever still persists high. Also that the virus applied to an abrasion of the skin made by scraping off the epidermis is unable to induce the disease, but subcutaneous injection of .5 c.c. imparts it. The virus in the blood serum of a yellow fever patient traverses the F bougie of a Chamberland filter without dilution, but not the B bougie. Virulent serum exposed to the air at a temperature of 24 to 30 C. becomes inactive by the end of forty-eight hours. In defibrinated blood kept under oil of vaselin at this temperature the microbe of yellow fever is still alive after five days, but does not survive to the eighth day. Virulent serum becomes harmless when heated. Preventive injection of this heated serum confers relative immunity, which may be rendered permanent by supplementing it with inoculation of a small amount of virus. Injection of defibrinated blood kept in the laboratory under oil of vaselin for at least eight days confers relative immunity. The serum of convalescents is endowed with unmistakable preventive properties, and seems to possess also therapeutic properties. The immunity conferred by serum from convalescents is still active by the twenty-sixth day. The *Stegomyia fasciata*, after sucking the blood of a yellow fever patient during the first three days of the disease, is not able to transmit the disease until after an interval of twelve days at least. The resulting infection seems to be graver the longer the interval that elapses. The mosquito bite does not always cause the disease, and does not confer immunity. Aside from the bite of this variety of mosquito the disease can be transmitted only by subcutaneous injection of blood taken from a yellow fever subject during the first three days of the disease. There can be no epidemic in the absence of the *Stegomyia*. The period of incubation may last for thirteen days. The causal agent of yellow fever still eludes research.

23. Treatment of Parasitic Alopecia by the X-Rays.—Sabouraud gives an illustrated description of the apparatus with which he has succeeded in curing tinea tonsurans in three months instead of the usual eighteen months' course necessary with other methods of treatment. This means an immense saving to the city of Paris, he remarks, as there are about 4,000 endemic cases of tinea and 650 are in the hospitals on account of this affection. The expense of treating them amounts annually to $90,000. This expense will be much lessened by reducing the length of treatment to one-sixth of the former time. He describes the few failures to the overlooking of some patch not discovered until later, or to reinoculation during treatment. In his extensive experience these failures have not amounted to more than 5 or 10 per cent. All the other patients have been permanently cured.

24. Diphtheria Antitoxin Treament by Various Routes.—Cruveilhier's experiments were all made on guinea-pigs under similar conditions. They demonstrated that in diphtheria, as in tetanus, after a certain period has elapsed, antitoxin is powerless, however introduced into the system. A single subcutaneous injection of .1 c.c. ten hours after inoculation of the animal with the diphtheria culture saved its life. Injection of 1 c.c. lengthened the safe period by two hours, as also injection of the smaller amount directly into the brain. In a few instances the period of safety was prolonged to fourteen hours. Intravenous injection proved the most effectual of all. The period of safety was prolonged in every instance to sixteen hours. The intravenous route, therefore, is the best for diphtheria antitoxin. It proved effective in these tests six hours after a subcutaneous injection had lost all efficacy.

35. **Catatonia.**—Several cases of this condition are described by Paris, who prefers for it the denomination "degenerative catatonic psychosis." He suggests that it should be considered as a syndrome of dementia precox, or as qualifying as "precocious" the dementia which follows the syndrome.

36. **Eye Lesions in Paresis.**—Raviart and Caudron publish the results of examination of some 44 paretics. They find numerous fundal lesions ranging from papillary atrophy through all the stages to the normal. It is most frequently unilateral. Only 6 patients had a normal fundus. The visual acuity, which was difficult to estimate, appeared very little diminished in most of the cases. About 80 per cent. of the cases had a history of alcoholism and 20 per cent. of syphilis.

39. **Unilateral Hallucinations in Ear Disease.**—Capgras reports a case and discusses it. He recognizes five different types of the relations of hallucinations of hearing with unilateral ear disease. The predisposition of the subject has much to do with the development. One type is that of a delusive but not hallucinative tendency, which puts on a delusive interpretation of the functional symptoms of the lesion which we should avoid mistaking for hallucination. The second type occurs where the unilateral lesion simply coexists with the hallucination; they are independent and have no characteristics indicating any relationship. In the third type the unilateral lesion may affect the sensorial element only, without any intellectual element. In this case, notwithstanding the unilateral lesion, the hallucination is bilateral, but it disappears with the cause which produces it. In the fourth class the unilateral lesion has no sensorial factor. It is not the provocative agent of the hallucination, but through the intellectual element, the unilateral type is produced. This character disappears only with the cure of the lesion and the hallucination becomes bilateral. Lastly, we have a type where the unilateral lesion plays a double part, uniting, so to speak, the two categories. It acts on the sensorial element and on the intellectual element. The first action causes the appearance of hallucinations and the second explains their unilaterality. The evolution of the lesion and that of the hallucination are parallel and their cure is simultaneous.

46 (No. 10.) *The Thenelles "Sleeper." Lancereaux.—La dormeuse de Thenelles. Un sommeil pathologique de 20 années consécutives.

42. **Therapeutic Application of Sea Climate.**—Robin formulates his views in regard to prescribing the sea climate in the statement that it is indicated when the vital processes are sluggish, but is distinctly contraindicated when there is excessively active metabolism. This excludes subjects with pulmonary tuberculosis as they are usually in the latter category. The stimulation of the sea air is particularly beneficial for anemic subjects with sluggish vital processes, for lymphatic, scrofulous and certain neurasthenic subjects with enfeebled nutrition. A small proportion of the tuberculous, about 8 per cent., exhibit normal or torpid organic interchanges, and this small class may find the sea climate beneficial. It may also aid consumptives who eat, digest and assimilate poorly notwithstanding excessive assimilation and disassimilation. Brief sojourn at the seashore may benefit such cases as also those in which the general health is still good and the lung lesions are healing. Such patients should be sent to a mild, equable climate and instructed to avoid winds and the cool of evening as also too brilliant sunlight, and to keep back from the immediate coast. The general and respiratory interchanges should be carefully examined from time to time and the patients sent away from the seashore if the findings become unfavorable. Tuberculosis of the bones and glands derives remarkable benefit from the sea air. Robin's work establishes the action of sea air and bathing on the organic interchanges, and thus confirms what has been learned by clinical experience.

43. **Lumbar Puncture in Otitis.**—Chavasse emphasizes the importance of the information to be learned by lumbar puncture in regard to endocranial complications of an otitis. When the cerebrospinal fluid is turbid or contains bacteria or polynuclear leucocytes or both, a bacterial meningitis is probable. An abundance of mononuclear lymphocytes in a clear or slightly turbid fluid speaks for tubercular meningitis. Lymphocytosis is also observed in other chronic meningeal processes and during retrogression of acute meningitis. In case of extradural and subdural suppurations the fluid retains its normal composition as long as the arachnoid sac is exempt. In case of a brain abscess, in thrombophlebitis of the lateral sinus and in non-bacterial meningitis the fluid is limpid and normal, but frequently under high pressure and more abundant than normal. Red corpuscles are liable to be found in the fluid after trauma of the basis or labyrinth, accompanied by symptoms on the part of the ear. Lumbar puncture should be combined with surgical intervention in otitic meningitis.

45. **Pelvi-Abdominal Syndrome in the Female.**—De Ranse describes a syndrome which includes pains, neuralgias, hyperesthesia, spasms, vasomotor disturbances, congestions, ptoses, functional troubles, etc. The syndrome involves the three systems, the genital, digestive and urinary, and treatment directed against any one of the triad is necessarily ineffectual as all three apparatus are involved owing to the direct nerve communication between them. The syndrome includes the "uterine syndrome" of the gynecologists, as well as dyspepsia, gastro-enteroptosis, hemorrhoids and symptoms in the urinary system. The system of plexuses in the abdomen controls the actions and reactions in the pelvi-abdominal organs and explains the pathologic connection between them. Hysteria and neurasthenia are frequently the primal cause of the syndrome which might aptly be called the pelvi-abdominal neuropathy. Treatment should aim to palliate the disturbances in the innervation and circulation of the parts and cure the general condition or diathesis in which they originate and which serves to maintain them. This double aim is realized by physical measures, fresh air, cold water, mineral waters,

heat, electricity, gymnastics and massage By its general and local action kinesitherapy responds to the numerous indications in these cases and merits greater attention on the part of practitioners Associated with balneotherapy it affords the most rational and effectual mode of treatment for this pelvi abdominal neuropathy, which persists unmodified after treatment of one of its factors if the others are neglected

46. The Thenelles "Sleeper."—THE JOURNAL mentioned last June the death of Marguerite B of Thenelles, France, who had passed twenty years in a pathologic sleep In May, 1883, after a severe fright, she fell asleep and did not rouse until in May, 1903, when symptoms of progressing tuberculosis seem to have recalled her to life for a few days, after which she succumbed to her tuberculosis Her father was alcoholic, her mother and sisters neurotic The various features of her long sleep confirm Charcot's dictum that the sleep of lethargy is only a modified hystero epileptic attack. When she roused she spoke the dialect of her childhood, but there were no signs of impairment of the nerve centers nor of the peripheral nerves and she took nourishment normally During her trance she had been fed by the rectum Her lethargic sleep had been accompanied every four or six weeks by sudden convulsions, each terminating by copious salivation or by a profound sweat Her unconsciousness was never relieved and no signs of intelligence were apparent during the twenty years of her sleep A small hysterogenic zone was found at the upper part of the sternum, the slightest touch to this region elicited convulsions Otherwise there was general anesthesia The case is reported by Dr F. Charlier of Origny Sainte Benoite (Aisne), and Lancereaux reviews a number of other cases resembling it to a certain extent, although in none on record did the trance last so long. There is no danger of any one's being buried alive in a trance as the temperature alone is sufficient to show the difference between the condition and death, even without the absence of signs of putrefaction The hysteric trance has never proved fatal in itself, but the lethargic sleep connected with melancholia entails a much graver prognosis as, for instance, in Semelaigne's case, in which after fifteen months of the trance the subject's face suddenly became congested, the respiration and pulse more and more hurried, and death replaced the pathologic sleep without the intervention of a gleam of consciousness Hypnotism, electricity and other agents have proved powerless against these trances, but if, as has been suggested, they are due to ischemia of the brain, remedies against this should certainly be tried As a rule, however, hysterics are best treated by being left alone Instead of making a great ado over their seizures he advises the family to leave them entirely alone and quit the room, and has never had a second attack occur among patients thus treated Raymond remarked in the discussion that he frequently had occasion to see subjects in such trances Every month on an average one is picked up in the streets and brought into his service He rouses them by moving the limbs, with other mechanical measures to arouse the benumbed psychic centers

47. Intratracheal Thyroid Tumors—The diagnosis of a tumor of this nature is probable when an otherwise healthy person between 15 and 40 years old exhibits symptoms of dyspnea and a flat, subglottic, smooth tumor of the rear or side wall of the trachea is discovered In very young subjects thyroid treatment might induce the retrogression of the tumor, but in older persons laryngotracheotomy is necessary in case the symptoms compel intervention This was done in the 5 cases reported by von Bruns, 4 of which he has previously published With the 6 he has been able to find in the literature there is now a total of 11 cases on record, with an additional case of malignant intratracheal struma on which he had occasion to operate All who have had anything to do with these tumors emphasize the importance of refraining from attacking them by the endolaryngeal or endotracheal route on account of the inflammatory swelling and suppuration liable to follow.

49 Fatal Hemorrhages After Tracheotomy—Taute adds 3 to the 82 cases of fatal hemorrhage after tracheotomy on record Arrosion of the anonyma is the most frequent cause, occurring in 65 per cent, while arrosion of the common carotid occurred in merely 4 7 per cent The veins are involved much less frequently than an artery On the whole, about 2 5 per cent of all cases of tracheotomy succumb in time to arrosion of some vessel Treatment is mainly prophylactic, watching against decubitus from the canula, noting blood in the sputa and localized pain In one of the cases described a threatening hemorrhage from the thyroid vein was effectually controlled, but usually such an occurrence is rapidly fatal. Children were the subjects in all but 10.6 per cent of the total cases of fatal hemorrhage

51 Cystic Dilatation of Ureter Within Bladder.—A young man had suffered for years from symptoms of chronic cystitis with retention of urine at times The trouble was discovered to be a cyst like enlargement of the ureter, projecting into the bladder. All disturbances ceased permanently after extirpation of the tumor

53 Operative Treatment of Prolapse of Rectum—Becker has treated 7 children and 4 adults by the technic which he describes and recommends as eminently fitted for the desired purpose After several days of purging, followed by rinsing out the rectum with hydrogen dioxid, he draws out the prolapsed portion and detaches the mucosa as a separate cylinder, which is removed, while the rest of the prolapsing wall is drawn up into folds by a number of stitches woven in and out, and it is pushed back inside the tissues He works through a circular incision around the anus, leaving the latter intact, as shown in the illustrations

58 Experiences with Natural Gastric Juice from the Pig.—Loeb reports from Ewald's clinic that the hopes cherished in regard to this new stomachicum were only imperfectly realized.

59. **Spastic Stenosis of Pylorus and Intermittent Ectasia.**—This communication issues from Boas' clinic, and is an exhaustive monograph on the subject and its literature. The diagnosis of spastic stenosis is of course by exclusion, and time will usually aid in establishing it. The prognosis of single attacks is good, although they leave a predisposition to repetitions, and when they occur often the pylorus is liable to become hypertrophied and the accumulation of connective tissue to entail secondary organic stenosis. The attacks generally respond readily to treatment. Korn has never observed but a single case which proved refractory and led to loss of weight, etc. He ascribes the spastic contraction to some underlying ulcerative or inflammatory process, and hence treats it as if it were an actual ulcer, guarding against recurrences with the same care as for the latter. Boas and others do not counsel surgical intervention for spastic stenosis alone unless it recurs so frequently as to cause much disturbance. Gastroenterostomy is the usual choice, but Neumann has recently warned that on account of the hyperacidity which is seldom lacking in these cases, jejunostomy may be preferable.

68. **Early Diagnosis of High Cancer in Rectum.**—Rosenheim insists that it is sometimes possible to diagnose malignant disease high in the rectum or flexure by palpation and endoscopy even in the earliest stages. In a case personally observed a rather nervous man, 42 years of age, noticed that defecation required more effort than formerly and that the feces occasionally showed traces of blood. Otherwise no symptoms could be discovered, spontaneous or elicited. Rosenheim examined him early one morning after the intestines had been thoroughly evacuated. He was able to introduce without difficulty a tube rectoscope 25 cm. long by 2 cm. in diameter—the subject in the knee-chest position. At the entrance of the sigmoid flexure the passage of the tube was obstructed by a fold of mucosa which was easily pushed aside, but behind it was a sausage-like roll projecting into the lumen from the lower left corner. This roll looked very red and the surface was drawn taut and was not modified by contact with the tube. As he was inspecting it flatus passed and a few drops of blood trickled from above the roll. He at once advised removal of the growth, which he assumed to be a carcinoma at the entrance. The surgeon to whom he sent the patient attributed the troubles to nervousness, as palpation under chloroform failed to confirm the presence of a tumor. Two other physicians consulted took the same view, although the patient's general health showed impairment during the following months. He finally drifted into the hands of a nature doctor for a month, but finally, one year after Rosenheim's first diagnosis, Israel was able to palpate a tumor and removed it with 15 c. of the intestine. The cancer by this time was the size of a small apple and was surrounded by smaller nodules. Rosenheim ascribes great diagnostic importance to the trickling of blood from above the tumor, which he has found is almost pathognomonic for cancer in the esophagus. Obstruction to the passage of the tube is also a grave sign, as ordinary infiltration yields to pressure and allows the tube to pass. In case of spastic contraction quiet waiting for a time will usually witness its subsidence and allow the passage of the tube. A permanent obstacle speaks for malignancy as also the circumscribed lesion. Visual inspection of the rectum and flexure is the only reliable means of discovering these growths in their incipiency as they then escape palpation, even when the examiner is gifted with unusually long fingers. He mentions the scant attention paid to the technic of bimanual palpation in the latest text-books, "not excepting Tuttle's great special treatise," and warns against trusting too implicitly to the findings of palpation, citing several instructive cases. He describes his own technic in detail and commends it as the most comprehensive of which he knows. The subject lies on a flat table, first in the Sims position, then on his back, and then in the high stone position, and the examiner explores the rectum with his forefinger, while with the other hand he presses the parts against the finger. It requires great skill to palpate a tumor above the third sacral vertebra. In the earliest stages the cancer may be too soft to give definite findings on palpation. In conclusion Rosenheim cites another case to illustrate the great advantages of endoscopy. He noted in this case papillary excrescences near the flexure. They were not much larger than hemp seeds, but bled at the slightest touch and the mucus taken from between them gave the reaction for blood pigment. The poor general condition suggested malignancy and a few weeks later numerous metastases were discovered. None of the symptoms in this case suggested the sigmoid flexure as the seat of the trouble except the direct visual inspection. He regrets that Tuttle did not give the particulars of the visual findings in the 5 cases he reports in which the diagnosis was based on endoscopy after failure of palpation. He urges the importance of publishing the exact findings in these cases to establish a composite picture of high cancer in the rectum. Sometimes the aspect is unmistakable, as in Ewald's 2 cases, in which the red, knobby, easily bleeding tumor masses forbade all doubt. Exploratory excision is not of much value in case of growths in the rectum as benign tumors so readily become malignant in this locality. One great value of endoscopy is in the relief afforded by negative findings. If the tube can be introduced for 35 cm. without hindrance and the mucosa appears sound throughout, then cancer in this part of the intestine may be safely excluded and attention directed to the parts which are more readily accessible to palpation, especially with the pelvis elevated.

70. **Nervous and Cardial Arrhythmia.**—Rehfisch presents a number of curves and arguments to illustrate his contention that arrhythmia of nervous origin may be differentiated from cardial arrhythmia by the lack of great differences between two neighboring pulses. He uses the word "differenz" to express the length of time required for the single phases of the pulse wave, in comparison with its sister waves. In 100 healthy working people examined at rest only 4 presented an absolutely regular pulse in this respect. The difference in 97 per cent. did not amount to more than 20 per cent. He calculates the percentage as, for instance, with 75 beats to the minute, each pulse lasts 16/20 of a second, but if two pulse waves require 19/20 of a second, this brings the difference to 18.75 per cent. In health he never found this difference to surpass 31 per cent., and in functional nervous disease it never surpassed 36 per cent. In cases of organic heart disease it reached 120 per cent. in some instances. He classifies a neurasthenic with a sound heart by having him step up on a chair several times in succession, noting the differences before and after. In merely nervous subjects the difference of two neighboring pulse waves does not surpass 40 per cent. Direct irritation of the vagus, as in meningitis, or by reflex action, as in appendicitis, does not induce any higher values in this difference percentage. Experimental research and clinical experience demonstrate that the extrasystole represents a relatively weak heart action while the decided arrhythmia in nervous subjects is generally, although not always, produced by extrasystoles. For all these reasons we can assume that cardial arrhythmia is distinguished from the nervous variety by its high difference values. We can further accept that when high difference values are accompanied by marked irregularities in the pulse there is usually some organic basis to be found for them in the heart.

72. **Successful Active Immunization Against Tuberculosis.**—[Moeller is director of the great Belzig sanatorium, and his work on the relation of the acid-fast bacilli to true tubercle bacilli received editorial comment in The Journal of March 5, 1904. He thinks the relation is similar to that between cowpox and smallpox. He found that by inoculating animals with some members of the group of acid-fast bacilli, in a certain sequence, it was possible to confer immunity against the later members of the series, and against true tubercle bacilli. The question was then to select one member of the group to use on man to render him similarly immune. He selected for this purpose the bacillus of blindworm tuberculosis as it is effective while it does not cause progressive lesions. The blindworm bacillus dies at a temperature of 25 C. He pro-

ceeded to inoculate himself and another subject with blindworm tuberculosis, commencing in March, 1902, and after repeating the inoculation once subcutaneously and three times into a vein, in December he made an intravenous injection of 1/50 of a loop of human tubercle bacilli. His general health and temperature were unaffected, but he lost about 15 pounds in weight during the following three months, but regained his normal weight in April. Two guinea-pigs were injected on the same date with the same amount of the same human stem culture One died in thirteen days with symptoms of pneumonia; the other was killed in eighteen days and a tuberculous infiltration was found at the point of injection and several nodules in the peritoneum. Moeller's general health has not suffered during the long interval since and he is still actively prosecuting this research, since publishing his report in the *Zeitschrift f. Tuberkulose*, v. 3, 1904. He is confident that in the blindworm cultures we have a means for successful vaccination against tuberculosis, on the same principle as cow pox vaccination against smallpox.—Ed.] In the present communication he replies to Friedmann's article, which was summarized in these columns on page 623

73 **Inhibition of Absorption by Adrenalin.**—Klapp injected dogs with milk sugar and then determined the proportion that had been absorbed, comparing them with dogs injected at the same time with the same amount of milk sugar plus adrenalin He found that even a single drop of the 1 1,000 solution had a decided effect in preventing absorption He thinks that all measures which induce anemia have an inhibiting effect on absorption. He gives the particulars of 21 tests, with a number of curves showing the quantitative absorption

76 **Operative Treatment of Tuberculosis of the Elbow.**—Damianos publishes the results obtained at Mosetig's clinic in operations on the elbow on account of tuberculosis Between 1892 and 1895 resection was done in 28 cases, with one death from pyemia Eighteen had been completely cured out of 19 examined in 1895. From 1896 to 1901, 32 cases have been operated on, with no mortality Out of 20 patients since examined 10 are completely cured with good function. Six have died and 4 required an insignificant after operation The technic includes a Bruns incision, sawing open of the olecranon, suturing it together again afterward He appends comparative tables of similar operations in various German clinics

79 **Volvulus of the Cecum.**—Faltin reports 2 new cases of volvulus of the cecum and 3 operated on by other Finnish physicians This makes a total of 35 cases of volvulus of the cecum published in Finland Most of the patients were less than 40 years old. The clinical picture includes the sudden onset, the vomiting, colic, obstipation, oblique or horizontal local meteorism. absence of peristalsis, moderate tenderness, comparatively chronic course, and late fecal vomiting. The patients usually assume a characteristic attitude. Out of 59 cases treated by reduction of the volvulus 28 have been cured, while only 3 recovered out of 9 in which resection of the gangrenous cecum was necessary. He remarks that on the whole we may ascribe a favorable prognosis to volvulus of the cecum.

80. **The Etappen Cast for Scoliosis.**—Marcuse has been much pleased with the plaster casts applied "by stages" to cure lateral curvature of the spine, especially habitual scoliosis. The results are most excellent if the patients are willing to persevere in the necessary after-treatment.

81. **Regeneration of Ligated Saphena.**—Ledderhose found in 2 specimens obtained at a secondary operation that the ligated and severed saphena in the thigh had become permeable again for the blood stream in time.

82. **Central Paralyses After Pregnancy.**—Hösslin reviews the symptomatology, prognosis and treatment of the various forms of central paralysis accompanying or following pregnancy and due to hysteria, myasthenia gravis, apoplexy, thrombosis, embolism or albuminuria, and he also reviews the relations of spinal affections to pregnancy. Delivery does not seem to be affected by spinal paralysis and conception and pregnancy proceed normally. In spinal affections delivery seems to be easier and quicker than in physiologic conditions In conclusion he urges physicians to pay more attention to the coincidence of cerebral paralyses with pregnancy, as he believes that it is more frequent than generally supposed.

83. **Early Narcosis**—Hofmann operates during the first whiffs of ether as his experience with hundreds of cases has shown that pain is almost if not entirely abolished and the muscles are completely relaxed. The depth and duration of the narcosis may be estimated from the condition of the muscles The patient is placed in the required position with clothing loosened and told to count slowly backward. When he is doing this tranquilly the ether is dropped on the mask and narcosis is complete in one to three minutes. If not complete, chloroform is substituted. Everything has been prepared beforehand for the operation, which is commenced at once so soon as the muscles are relaxed. The few drops of chloroform used to supplement the ether are preferable to the exclusive use of ether. He regards this as the ideal narcosis.

84 **Ether Drop Narcosis.**—Barten proclaims from Berndt's surgical service at Stralsund that the ether drop narcosis is the least dangerous of all methods of narcosis known to date, while its technic is the simplest

85 **Bier's Passive Hyperemia.**—Luxembourg has treated 50 patients with various joint affections by the application of Bier's technic of passive venous congestion. He uses a thin, transparent rubber band for the ligature, applying it for an hour morning and evening. Careful analysis of the material has shown that this simple, inexpensive and painless procedure is a most effectual mode of treating joint affections. The prompt relief of the pains is one of the best features of the treatment

87. **Diagnosis of Pulmonic Incompetency.**—Fromherz reports 2 cases in detail, with the features in common of dyspnea and oppression in the chest, extreme hypertrophy of the right ventricle with relatively good heart action. There was also hypertrophy of the left ventricle, the apex beat in the mammary line. In both there was also a *systolic* murmur with the maximum in the second interspace to the left of the sternum, the second sound over the pulmonary well audible and also the diastolic murmur. A still more important symptom was the hyperglobulia, which is almost a constant accompaniment of long-standing vices of the right heart, that i-

to say, conditions which induce disturbances in the domain of the pulmonary artery, especially those disturbances which diminish the total surface of the blood being oxidized. This hyperglobulia is not to be regarded as an evidence of disturbed compensation, but as an effort at compensation. The increase in the number of red corpuscles at high altitudes may be likewise viewed from this standpoint. The differentiating points between imperfect closure of the semilunar valves of the pulmonary artery and other pathologic conditions are enumerated, showing that the condition can be differentiated by exclusion if in no other way, and rational treatment depends on proper diagnosis.

88. **Nose Built Out of Arm.**—Habs' patient had entirely lost the nose and its bony support in consequence of lues. He made a new nose out of the arm by the technic shown in fifteen illustrations, with surprisingly fine cosmetic results. His technic differed from all others in that the strip of bone selected, covered with normal periosteum, was transplanted into the flap of skin that had been turned back above it. The raw surface of the split bone was turned toward the cutis, while a bridge of periosteum still connected it with the rest of the bone. The flap was then replaced and time left for adhesions to form between the bone and the under surface of the cutis. The bridge of periosteum was then severed and the free end of the flap turned down over the strip of bone. The bone was thus covered with good skin on both sides, and after three weeks' fixation of the arm to the face the flap was detached from its base and sutured in place. The lower quarter of the flap was then bent in at a right angle to give the nose the proper shape.

91. **Lumbar Puncture in Uremia.**—Seiffert has had extensive experience with lumbar puncture in uremia and has invariably found that the cases thus treated all recovered. In less than half an hour there is an amazing improvement in the condition. In his cases the uremia was due to scarlet fever. Lumbar puncture might prove equally effective in uremia from other causes, especially in eclampsia, but he has had no opportunity to give it a trial. He found the procedure a life-saving measure also in the initial convulsions of scarlet fever and of measles, although his experience with such cases has been limited. Even while the puncture was in progress consciousness returned and the convulsions ceased. It was impossible for him to test the cerebrospinal fluid obtained in these cases to learn whether it contained a specific toxin for animals.

93. **Electric Bell to Arouse Attendant.**—Büdingen gives an illustration of a simple contrivance to place under the rug by the bedside. As soon as any one steps on the rug an electric current is closed and a bell rings wherever desired. This bell is particularly useful in insane asylums, as it gives notice whenever a patient gets out of bed.

94. **Treatment of Hydrophobia.**—Georgescu describes the mode of treating rabies adopted by Babes. Besides the Pasteur treatment the principles of serum treatment are also applied, injecting the blood of immunized dogs, asses or horses. In addition Babes has discovered that the blood of persons who have undergone antirabies treatment acquires preventive value. The combination of all these measures has enabled cures to be realized, even when a much longer time has elapsed than hitherto supposed allowable. As it is difficult to obtain human blood for the purpose, he generally uses for injection the rabic toxins which he has isolated. This combined treatment has a much more powerful and more rapid action in the organism, the length of treatment is materially reduced and the mortality has been *nil*.

95. **Preservation of Raw Meat.**—A. Babes cuts the pieces of meat with as smooth a surface as possible, and then lifts them with an iron hook and dips them in a 2 per 1,000 solution of potassium permanganate. They are left in the fluid for twenty to thirty seconds, and then hung up in a ventilated room. By the third day the outside has dried into a protecting cover, which isolates the rest of the meat. In the course of a few weeks it becomes impossible to grow bacteria, even on slices cut from the meat.

96. **Proliferation Processes in Adenoid Tissue of Digestive Tract.**—Stoerk gives a number of illustrations of a peculiar proliferation. The surface of the stomach or intestines presents rolls or folds or disseminated bunches in the adenoid tissue suggesting lymphosarcomatosis, but there is no regional progression. The affection seems to occur universally from the start, or at least in more than one region at once. There is no metastasis nor involvement of adjacent organs, as in lymphosarcomatosis, and the microscopic findings speak against pseudoleukemia, although the affection has features suggesting both. The clinical picture comprised alternating diarrhea and constipation—the patient a working woman of 57—with edema, increasing weakness, "stabbing" pains in the abdomen, and small tumors could be palpated resembling parts of a fetus. Death in eight months. The necropsy showed the proliferation of adenoid tissue above described, extending through the stomach, but most pronounced in the large intestine, especially below the flexure. The second case was a woman of 26, and the lesions were restricted to the small intestine. Death occurred in consequence of perforation at two points in the lower ileum, through ulcerated nodules.

97. **Radium Treatment of Cancer of Esophagus.**—Exner's successful treatment of impermeable cancerous stricture of the esophagus was mentioned on page 929 of The Journal. He uses a No. 16 bougie, and screws on it a cylindrical hard rubber capsule, a rounded tip fitting into a hollow cylinder of the same. Between these two parts is inserted the scrap of radium —not more than 60 mg.—imbedded in dammar. The radium causes cavities in ulcerative carcinomata, due to necrotic breaking down of the tissue. This property of the radium renders permanent the enlargement of a cancerous stricture by this means, but it entails the possibility that perforation may be induced or hastened with too large dosage. He describes the details of 3 cases. All the patients had been treated by instrumental dilatation, with only transient benefit. The radium was applied seven times for twenty minutes during two weeks in the first case; in the second, four times for thirty minutes each in the course of eight days; in the third, six times for

thirty minutes each during a corresponding number of days, and twice more after suspension for nine days. Two other cases were treated with about the same technic, and the results have been apparently perfectly successful in each. Still another patient was treated before the technic was perfected, but the progress of the cancer was such as to render palliative efforts useless, and he died in less than four months.

98. **Cryoscopy and Reflex Polyuria.**—Kapsammer writes from the Vienna Institute for Experimental Pathology that his and Paltauf's experience has demonstrated that catheterization of the ureters is liable to entail a reflex polyuria which may prove misleading in the functional tests. He emphasizes the necessity of catheterizing both kidneys, and of paying due heed to the amount of urine, comparing it with the normal average, which he believes is .5 c.c. to the minute for each kidney. Particular attention should also be paid to the escape of urine outside the catheter.

102. **Cystitis in Children.**—Girls are subject to cystitis more than boys, but Zelenski reports 4 cases observed in boys between 4 and 12. One was due to a coccus, the invasion favored by trauma, the others to tubercle bacilli, although the general health was good. In 2 cases the kidney had evidently been primarily affected and in another there had been a preceding tuberculous fistula in the epididymis None of these cases was permanently cured.

104. **Pathology of Tropical Indians.**—Effertz has resided for six years in southern Mexico, at one of the hottest points He has noticed that tuberculosis always takes the galloping form among the natives, fatal in three months in apparently the most robust subjects On the other hand, their resistance to traumatisms is amazing He was superintendent of the hospital at Pochutla, which has only three wards, and the one that happens to be empty is used for the morgue There is no flooring and no bed linen The patients lie on duck cots and the duck, being nailed on, is never washed. The families of the patients are supposed to attend to the cleaning of the room. Two of the patients were brought in moribund. With these exceptions he never lost a patient during his régime and never had a case of "wound fever," although the wounds are always severe and usually multiple, generally the result of a drunken fray in which the huge knives, the 'machetes," are freely wielded They resemble an old Roman sword in shape and almost in size. The skull was opened in many instances and the dura visible Other patients had the ribs broken in and breathed through this artificial opening All recovered under kreolin dressings without surgical intervention and without fever Smallpox has a mortality of 75 per cent among these Indians Malignant forms are the rule at the onset of an epidemic He never had occasion to observe cases of recent syphilis, nor any of tabes or paralysis, nor tertiary lesions Although extremely refractory to syphilitic infection, yet the disease exists among them Testimony to this fact was afforded by the fulminating form of syphilis acquired by a European from intercourse with the Indian women Effertz suggests as a possible explanation for these paradoxical facts that tuberculosis and smallpox are comparatively new diseases to these Indians, while syphilis has been with them for centuries and has thus conferred a kind of immunity on the race. The reverse is true of Europe, where tuberculosis and smallpox are the old diseases and syphilis the new one He is convinced that all diseases have a tendency to die out in time and that the last phase they pass through before their final extinction is the venereal phase, that is, requiring more intimate contact for infection The day is coming, he thinks, when syphilis will have entirely vanished and tuberculosis will have subsided into an exclusively venereal disease—the stage in which syphilis now is at present in man. In animals it has already passed beyond this stage and completely died out, leaving permanent immunity. This hereditary immunization against syphilis explains the fact that as immunization progresses the therapeutic effect of drugs increases in proportion, and consequently when a disease has arrived at the venereal stage there will always be a better chance for a successful specific.

105. **Reflex Pathology of the Skin.**—Kreibich had a patient, a hysteric young woman, who submitted to various tests which demonstrated the possibility of causing in fifteen minutes by reflex action various cutaneous affections. He attributes them to irritation of the walls of the vessels by nervous influences. The walls become permeable and allow the passage of fluids. Large effusions are thus forced out under high pressure into the fibers of the cutis and the epithelium, causing vesicular eczema, which is thus in certain cases due to a nervous influence by the reflex route on the vasomotors. His tests establish the possibility of a nervous origin by reflex action for many kinds of skin affections from mere hyperemia to gangrene, the primary irritation being central.

107. **Sugar Formation in Liver Tissue Preserved in Alcohol.**—During Seegen's last illness he urged the immediate publication of this, his last work, to call attention to the discovery mentioned in the title. It modifies our previous conceptions of the mechanism of sugar formation Since his announcement that under certain circumstances no glycogen could be found in the liver immediately after death, he has been constantly studying the subject of glycogen formation. The chopped liver of dogs was examined for glycogen and sugar at once after death and again at intervals after the liver had been set aside in alcohol. In one experiment the liver contained 9 per cent. sugar at once after death and 7.9 per cent after having been five days in alcohol. In another the percentage was at first 1.1 and after seven days in alcohol it amounted to 7.4. The total sugar increased in like proportion The elaboration of sugar continued under the surface of the alcohol. The theory that the elaboration of sugar is a function of the living cell is disproved by these facts. Instead of the mysterious vital forces of the living cell we must admit chemical action as a factor in the production of sugar. The action of enzymes as an essential factor in the process of elaboration of sugar is likewise excluded by these new facts Hence the assumption that the liver sugar is derived from the liver glycogen is refuted once for all

109. **Mode of Retrogression of Cancer Metastases Under Radium Rays.**—Exner was able to trace histologically the retrogression of carcinomatous nodules in the mamma in one out of the 2 cases described. The findings were controlled by histologic examination of excised, non-exposed nodules. He found that exposure for a single half hour was able to induce complete retrogression of a nodule in the cutis The retrogression was complete in five weeks. The most remarkable feature of the phenomenon is that while the cancer cells retrogress none of the other elements of the cutis is destroyed. He gives 8 illustrations of the findings They show that within a week of the exposure there is a new formation of connective tissue, while at this time the cancer cells show no change There are numerous new formed capillaries in the new connective tissue No change appears in the cancer cells (vacuolization) until two weeks have elapsed. The rapid proliferation of connective tissue seems to spread the cancer cells apart and overwhelm them by its growth, actually squeezing them to death The exposed cancer tissue thus behaves like a transplanted fragment of an organ It does not succumb to rapid necrosis, but is grown through by the surrounding tissues and slowly absorbed However this may be, one thing is certain, namely, that the physiologic relations of growth between the cancer cells on the one hand and the connective tissue on the other are disturbed The latter is stimulated to a proliferation which chokes out the former. Whether the exposed cancer cells suffer in their vitality from the effects of the exposure and thus become less resistant, is still a matter for conjecture

111. **Polycythemia with Enlarged Spleen and Pigmentation.**—Turk has encountered 7 cases of this symptom complex since 1900. He analyzes them in detail and mentions that he had very promising results from administration of large doses of arsenic in one case. He proposes to use it further if he happens to meet any more patients with this affection. He administered it on the grounds that arsenic checks the pro-

liferation of the blood-forming tissues. He has had occasion to note this fact repeatedly in myeloid leukemia. He administered progressive doses up to 30 drops of Fowler's solution daily, keeping it up for months. The number of erythrocytes diminished under this medication by one and one-half millions, the hemoglobin by 4 gm. to the 100 c.c. of blood. The intense purpura pigmentation vanished almost completely, *and the* spleen became very much reduced in size. Of course the toxic effects of arsenic must be considered, so that the drug can not be kept up indefinitely, but the results encourage further attempts in this line.

116. Gastrointestinal Anastomosis Without Opening the Lumina.—Sato studied on dogs and monkeys the behavior of two submucous surfaces in contact in the intestinal tract. He found that simple contact, even when the serous and muscular coats had been removed, did not lead to a communication between the parts, but that when the parts in apposition were treated with a caustic an opening was soon established. In monkeys this occurred in less than twenty-four hours. The silver nitrate pencil is more convenient for the purpose than the thermocautery, and the moist caustic causes less damage than heat. He incises and detaches the serous and muscular coats at the spot and applies the silver pencil about 1 or 2 mm. from the edge of the wound, carefully sponging away any excess of the nitrate that may be dissolved. The surfaces are then sutured together according to Czerny's technic. The lumina are not opened until nearly twenty-four hours after the surgical intervention, thus affording better conditions for repair. The operation is extremely simple and rapid.

117. Refrigeration Treatment of Granulating Wounds.—Stiassny sprays the wound with ethyl chlorid after protecting the ulcerating portion with an insoluble salve. He tabulates the details of 48 cases thus treated. His conclusions are that this treatment is liable to prove a valuable adjuvant to other measures in case of leg ulcers, although it is not always successful. It is particularly beneficial in granulating effects on a traumatic basis. The surrounding tissues are sound in these cases and respond to the stimulation of the cold application. He uses for the protecting salve a mixture of equal parts of lanolin and vasogen and one-tenth Peruvian balsam. The best results were obtained with hospital patients, as they could be sprayed two or three times a day, while the outpatients were seen only two or three times a week.

121. Osmotic Pressure and the Organism.—Kiss reviews what is known on this subject and points out that the theory of osmosis is far from explaining the processes observed in the living organism. These processes resemble physical processes under certain aspects, but they differ from them in many points, such as, for instance, the fact that they generally occur much more rapidly. The *reaction of the cells* is always physiologic, not purely physical. The cell works with molecules and ions and probably utilizes also the forces of osmosis, guiding and transforming them to suit its purpose, but the *modus operandi* is to date still a mystery.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Perpetual Visiting and Pocket Reference Book. Including Information in Emergencies from Standard Authors, also the Following Comprehensive Contents: Table of Signs and How to Keep Visiting Accounts, Obstetrical Memoranda, Clinical Emergencies, Poisons and Antidotes, Dose Table, Blank Leaves for Weekly Visiting List, Memorandum, Nurses' Addresses, Clinical Record, Obstetrical Record, Birth Record, Death Record, Vaccination Record, Bills Rendered, Cash Received, Articles Loaned, Money Loaned, Miscellaneous, Calendars for 1904 and 1905. Bound in Morocco, Red Edges. *Pp.* 124. *Price, Free* (postage 10 cents). St. Louis, Mo.: The Dios Chemical Company. 1904.

Laboratory Manual of Physiological and Pathological Chemistry, for Students in Medicine. By Dr. E. Salkowski, Professor in the University and Director of the Chemical [illegible] Pathological Institute, Berlin. Authorized [illegible] Second Revised and Enlarged German Edition. By W. [illegible] A.B., *Ph.D., Professor* of Organic and Physiological Chemistry in Cornell University. With 10 Figures and a Colored Plate of Absorption Spectra. First Edition. First Thousand. Cloth. Pp. 263. Price, $2.50. New York: John Wiley & Sons. 1904.

Abbott's Alkaloidal Digest. A Brief Therapeutics of Some of the Principal Alkaloidal Medicaments, with Suggestions for Clinical Application Embodying Various Articles on Important Special Agents and Certain Great Phases of Alkaloidal Therapy That Have Been Developed in My Personal Practice. By W. C. Abbott, M.D., Editor of the Alkaloidal Clinic. Flexible Leather. Price, 50 cents. Pp. 54. *Chicago:* The Clinic Publishing Co. 1904.

Atlas and Epitome of Operative Gynecology. By Dr. O. Schäffer of Heidelberg. Edited, with Additions, by J. Clarence Webster, M.D. (Edin.), F.R.C.P.E., *Professor of Obstetrics and Gynecology* in Rush Medical College, in Affiliation with the University of Chicago. With 42 Lithographic Plates in Colors. Cloth. Pp. 138. Price, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

A Manual of Clinical Diagnosis by Microscopic and Chemical Methods. For Students and Practitioners. By Charles E. Simon, M.D., Late Assistant Resident Physician at Johns Hopkins Hospital, Baltimore. Fifth Edition, Thoroughly Revised and Much Enlarged. Pp. 695, 150 Engravings, 22 Colored Plates. Cloth. Price, $4.00 net. Philadelphia and New York: Lea Brothers & Co. 1904.

A Practical Treatise on Nervous Diseases. For the Medical Student and General Practitioner. By F. Savary Pearce, M.D., *Professor in Nervous and Mental Diseases* in the Medico-Chirurgical College of Philadelphia. Colored Frontispiece, 91 Illustrations in the Text, Many in Colors. Cloth. Pp. 401. Price, $6.00. New York and London: D. Appleton & Co. 1904.

Air, Food and Exercises. An Essay on the Predisposing Causes of Disease. By A. Rabagliati, M.A., M.D., F.R.C.S. Edin., Honorary Gynecologist, and Late Senior Honorary Surgeon, Bradford *Royal Infirmary. Third Edition, Greatly Enlarged and Almost Entirely* Rewritten. Cloth. Pp. 559. Price, $3.00 net. New York: Wm. Wood & Co. 1904.

Directions for Laboratory Work in Physiological Chemistry. By Holmes C. Jackson, Ph.D., Assistant Professor of Physiologic Chemistry in the University and Bellevue Hospital Medical College. Second Edition, Rewritten and Enlarged. First Thousand. Cloth. Pp. 148. Price, $1.25. New York: John Wiley & Sons. 1903.

The Value of Ureteric Meatoscopy in Obscure Diseases of the Kidney. A Study in Clinical and Operative Surgery. By E Hurry Fenwick, F.R.C.S., Surgeon to and a Lecturer on Clinical Surgery at the London Hospital. Cloth. Pp. 219. Price, $2.30 net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

Diseases of the Intestines. A Text-Book for Practitioners and Students of Medicine. By Max Einhorn, M.D., Professor of Medicine at the New York Post-Graduate Medical School and Hospital. Second Revised Edition. Cloth. Pp. 397. Price, $3.00 net. New York: Wm. Wood & Co. 1904.

Informe Mensual Sanitario y Demografico de la Republica de Cuba. Presentado al Secretario de Gobernacion Sr. Eduardo Yero Buduen por el Dr. Carlos J. Finlay, Jefe de Sanidad de la Isla de Cuba. Diciembre, 1903. Paper. Pp. 61. Junta Superior de Sanidad de la Isla de Cuba.

Immune Sera. Hemolysins, Cytotoxins and Precipitins. By Professor A. Wassermann, M.D., University of Berlin. Authorized Translation. By Charles Bolduan, M.D. First Edition. First Thousand. Cloth. Pp. 77. Price, $1.00. New York: John Wiley & Sons. 1904.

Lectures, Chiefly Clinical and Practical, on Diseases of the Lungs and the Heart. By James Alexander Lindsay, M.D., F.R.C.P. (Lond.), M.A., Professor of Medicine, Queen's College, Belfast. Cloth. Pp. 447. Price, $3.50 net. New York: Wm. Wood & Co. 1904.

Address.

SURGICAL TREATMENT OF NEPHRITIS.

(BRIGHT'S DISEASE.)[*]

ALEXANDER HUGH FERGUSON, M.D.

Professor of Clinical Surgery (P. and S.) Medical Department of Illinois University; Professor of Surgery, Chicago Post-Graduate; Surgeon-in-Chief, Chicago Hospital, etc.

CHICAGO.

As early as 1889 I explored the right kidney of a young man, 24 years of age, who presented symptoms of stone. There were pain and tenderness in the region of the kidney, and attacks of renal colic with hematuria at irregular intervals. No calculus was discovered by the exploration, but he was relieved of his colics and hemorrhages for some time. Four years later he died of Bright's disease.

For the next seven years my experience with the fixation of floating kidneys impressed me with two facts: First, that a symptomatic cure was obtained when the organ was suspended by its rolled-off capsule, the nephralgia passing away and the urine becoming normal in quantity and quality; and second, that in cases diagnosed as nephralgia and floating kidney, when this was not done, but a simple nephropexy performed instead, many of the cases were not benefited by the operation. I recollect in 1890 operating on one of these a second time, on account of pain in the region of the kidney, where a stone was suspected. In my exploration the capsule was peeled off and the kidney opened and punctured. This effected a cure, and she is alive and well, Nov. 22, 1903 (by letter).

A more careful study of the cases of tender and floating kidneys revealed phenomena which gave us an increased interest from a clinical standpoint. The difference in the character of the pain, from sensations of a dragging weight or constant dull ache when on the feet, often eased when lying down, to severe paroxysms like renal colic; or, again, to exacerbations of pain of a neuralgic nature, sometimes extending to the nerves on the affected side, was suggestive of the existence of different conditions in the kidneys that had left their normal positions. The nausea, vomiting, anorexia, diarrhea, constipation, flatulence, debility, frequent urinary disturbances, emaciation and depression of spirits or mental confusion, often found in these cases, are no doubt expressions of mild uremia in nephritis, and not due, as we formerly supposed, to floating kidney *per se*.

It has been many times disputed that movable kidney produces any effect on the character of the urine. When a person with a floating kidney seeks advice, with often a history of scanty urine, high-colored, a sedimentary deposit, or at other times it is more copious than normal, and blood, hyaline and granular casts and albumin are found in it, there is a nephritis present as well, and whether the inflammation or the floating kidney existed first is often doubtful.

The graver condition now is the nephritis, and decapsulation and nephropexy are indicated. That a nephritis was present in the vast majority of my cases, I have verified by a microscopic examination of a portion of kidney tissue removed at the time of the operation. In three instances of floating and tender kidney met with since January, 1899, no changes were present in the kidney tissue. The pain and tenderness in them must have been caused by something else—congestion, nephralgia, twisting of the ureter, etc. This is positive proof that they are not all cases of nephritis, as I formerly supposed.

The only accurate means of diagnosing the condition of a kidney that is floating and tender, with no changes in the urine, is by a microscopic examination of a portion of the kidney. It is not infrequent to find interstitial nephritis (microscopically) when no albumin or casts are in the urine prior to the operation, which are instances of "nephritis without albuminuria." On the other hand, chronic Bright's disease may be present in floating kidneys, where pain was not a symptom nor tenderness a sign, but in what percentage I do not know. In my experience, I have refused to perform nephropexy, because Bright's disease was present as well as the floating kidney.

Do not these facts teach us that all floating kidneys should be suspended by their own stripped-off capsule, whether they are painful and tender or not, for by so doing we surely prevent the organ from again wandering; and, what is still more important, the progress of a destructive disease in a large percentage of cases may be cut short. I have yet to see a case in which decapsulation and suspension of a normal kidney did harm.

During 1897 and 1898 I frequently expressed the opinion at my clinics that a certain form of Bright's disease (interstitial nephritis) was always connected with a tender floating kidney, and was symptomatically cured by stripping off the capsule and suspending the kidney; but we now know this is not always the case. While formerly my object in the treatment of these cases was to put the kidney at rest, now, however, on account of the frequency with which inflammation occurs at the same time, the treatment of the latter becomes the more important.

On June 17, 1896, at the Chicago Post-Graduate Hospital, I performed decapsulation for nephritis and floating kidney in a young girl, with excellent immediate results. I was assisted by Drs. W. A. Tichenor and E. M. Brown.[1] My first double decapsulation for nephritis and floating kidney was performed also at the Post-Graduate Hospital, on Dec. 9, 1897, assisted by Drs. E. M. Brown and W. A. Tichenor, and in the presence of a large class of doctors from different states.[2] The immediate result was amazingly good. It is now over six years since I operated on this woman. She is in better general health than she has been for the last eighteen years. I have had her urine examined four times the last month, with the same report each time, as follows: In twenty-four hours, 60 ounces. No albumin; no sugar; no casts; no blood; urea 1½ per cent.

---

[*] The President's Address, delivered before the Western Surgical and Gynecological Association, at the Thirteenth Annual Meeting, held at Denver, Colo., Dec. 28 and 29, 1903.

This case is important for many reasons. Chief among them are:

1. That her right floating kidney was fastened a year previously by stitching it in place by a good gynecologist, without splitting or peeling off the capsule, but thereby she was not relieved.
2. Decapsulation relieved this same kidney of pain and tenderness.
3. The double decapsulation so far has cured her interstitial nephritis.
4. Six years last September 9 seems a fair time test.

On Dec. 16, 1898, in a discussion at the Chicago Gynecological Society on "Movable Kidney," I advanced the following ideas:[3]

"On the kidney being exposed, its condition is to be considered. If there be a firm adherent capsule to the kidney, it had better be stripped off, as, for instance, in interstitial nephritis. The stripping off of such a capsule improves the condition of the kidney, in that it liberates its cortical portion, and we observed the improvement in the urine afterward.

"I do not wish to be misunderstood with reference to removing the normal capsule of a kidney. I condemn this, and I do not do it. But the peeling off of a thick, pathologic capsule is a thing that is desirable. I have gone into the subject at considerable length in my surgical work, and the distinguished Professor Klebs agrees with me that where we have a thickened, fibrous, pathologic capsule, pressing on and destroying the kidney, it is a good sound surgical practice to peel off the capsule."

This was before I had removed portions of kidney for microscopic examination, but the opportunity to do this soon arose. Before the Chicago Academy of Medicine, Feb. 10, 1899, I mentioned my early work, and reported two cases of interstitial nephritis and floating kidneys, giving a microscopic report of sections. My paper appeared in The Journal March 18, 1899.

These two cases were operated on January 4 and 14, 1899, respectively, and are still, from a recent report, in good health.

In about a month later, Dr. G. M. Edebohls published his first article, entitled "Chronic Nephritis Affecting a Movable Kidney, as an Indication for Nephropexy."[4]

In my work I am pleased to report progress in all the cases reported at New Orleans last May. Between four and five years ago only two surgeons, Dr. Edebohls and myself, were decapsulating kidneys for Bright's disease. Since then no less than about forty surgeons have reported cases.

These have been collected by Dr. Ramon Guiteras of New York, and number 120 cases in all. I wish to add three important cases to this list.

Case 1.—*Renal Decapsulation and Puncture for Acute Diffuse Nephritis. Death.*—June 12, 1903, Dr. Ira H. Rea called me to see a case with him and Dr. W. H. Waugh, at Wheaton, Ill. The patient, a man 56 years of age, had been ill with acute nephritis for twenty days. He was a merchant, visited Wisconsin on business, and there caught cold while driving through the country. When Dr. Rea saw him on his return, his urine was scant, 30 ounces in twenty-four hours, and very bloody, but contained no casts. He then complained of pain in the region of both kidneys, and felt very ill. He was a man of excellent habits, and never before gave any evidence of nephritis. The doctor had been treating him for stomach disturbances off and on for several months. During this period he had an analysis made of the urine several times by Dr. W. A. Evans of the Columbus Medical Laboratory, and at no time did it contain the slightest evidence of kidney disturbance or disease. A few months previously he passed for life insurance. Dr. Rea also had made examinations of his urine repeatedly, with negative results.

When I saw him, on the twentieth day of his illness, he was *in extremis.* A general puffiness of the face and extremities, a rapid respiration (thirty-six per minute), and an uncontrollable drowsiness, with persistent vomiting, presented an unmistakable picture of his condition. He had only passed 8 ounces of urine in six days, which contained blood; urea, 1 per cent. per vol., but no casts. He had been kept profusely perspiring for days, and this accounted in part for the scant urine. It appeared that he responded to treatment very well the first few days, and even got out of bed. A relapse of his symptoms stubbornly resisted all medication and attention.

Decapsulation of his kidneys was discussed. It was clear that he was about to pass away before long, and everything else had been already done. With the distinct understanding that possibly an operation might relieve him, I undertook the procedure on the right kidney there and then, assisted by Drs. Rea, Waugh and Norman H. Ferguson. Local anesthesia (cocain) was used until the kidney was exposed. The traction on the forceps grasping the fat gave him pain, so a little chloroform was administered to the point of analgesia, and the kidney decapsulated, punctured, and a V-shaped piece removed. The bleeding from where the section was removed was so profuse that a couple of mattress sutures of catgut had to be passed to control it. The kidney was about normal in size, nodular on its surface, and of a dark blue color. It felt tense, and its capsule was blistered and separated here and there from the cortex by bloody serum. On splitting it, bloody serum escaped, and no difficulty was experienced in peeling out the kidney with my finger. The capsule easily tore, and it was nearly all removed. With the capsule removed, the kidney was dark red in color, and firm and friable in consistency.

In my judgment, here was a condition in which many punctures were indicated. My objects in puncturing a diseased kidney in many places are: (1) To relieve tension; and (2) to open many glomeruli, urinary tubes and blood capillaries. From these openings blood, serum and urine come from the kidneys at once into the dressings.

To come back to this case, I drained the wound with a rubber tube and plain gauze. He died in fifteen hours after the operation from edema of the lungs, for his lungs filled up, and he never regained consciousness. In my opinion, he died sooner than he probably would have if left alone. No urine entered the bladder after the operation, but the dressings had to be changed several times, and they were soaked with a bloody fluid, having the odor of urine.

Pathologic Report.—A study of many sections of the portion of kidney tissue showed an acute diffuse inflammation engrafted on a chronic interstitial nephritis. The malpighian bodies suffered severely, their epithelium being degenerated and necrotic here and there. The streaks of red running through the specimen were linear hemorrhages. The small, mottled, grayish-red spots were the epithelial cells of the convoluted tubes and malpighian bodies greatly proliferated, degenerated and necrosed. The capillaries of the tufts were filled with cells and thrombi, with leucocytes and red blood corpuscles within Bowman's capsule. There was cloudy swelling; fatty and hyaline degeneration of the tubular epithelium. Along with these parenchymatous changes, the interstitial ones were fully as marked. Small-celled infiltration occurred about the capsules and between the tubes, and active proliferation of the connective tissue. Chronic changes were manifested by an increase of the connective tissue surrounding the malpighian bodies and convoluted tubes, as well as hyperplasia of the walls of the blood vessels and thickening of Bowman's capsule. Bloody, hyaline and granular casts were pent up in several places within the tubules.

IMPORTANT FEATURES OF THIS CASE.

1. Chronic interstitial nephritis, with every evidence of granular kidney without any previous symptoms or signs. If a microscopic examination of a portion of the kidney had not been made, the case would have gone down in history as one of acute nephritis.

2. The severity of the acute diffuse nephritis without other apparent cause than exposure to cold is remarkable. It was so severe that it might be called "hemorrhagic nephritis," which, however, is more characteristic of intense septic and infectious cases.

3. Operation was of no avail, because it was too late in being performed. This case supported the view that acute nephritis is considerably within the scope of the surgeon's work. We are convinced that if double decapsulation and puncture had been performed within a week of his illness, he would at least be alive to-day. I am of the opinion that in acute inflammations of the kidneys the consultant should be the surgeon. In this man the surgical treatment of his kidneys should have been the same as of a phlegmonous inflammation of his hand, in which free incisions would have been promptly made to relieve tension, and to liberate imprisoned poisonous materials. It is through a study of surgical pathology, especially where the elements of the disease are caught red-handed, on the operating table, that true conservative surgery can be unassailably established.

Case 2.—*Interstitial Nephritis, Chronic, Double Decapsulation. Recovery.*—(Surgical clinic at the College of Physicians and Surgeons, Chicago, Nov. 20, 1903.) I operated on this man, who has just walked in to report himself, four weeks ago for chronic, interstitial nephritis, and, as you will remember, his two kidneys were decapsulated at the one sitting. The surgical treatment of nephritis is not mentioned in your textbooks. I am, therefore, constrained to give a brief review of this case, and also of the one I operated on a week ago. He is 45 years of age, strongly built, of better habits than formerly, and a Chicago politician by occupation. He was employed as a street-car conductor sixteen years ago, but had to give it up on account of pain in his back.

Condition on Admission (Nov. 16, 1903).—The face, hands and feet were swollen and edematous. Under the lower eyelid pitting on pressure was not as marked as on his feet and ankles, and still less on his hands. The conjunctivæ were chronically congested (red), and his eyesight was so poor that he could not recognize his friends very well. He had the appearance of one who had been drinking heavily for a long time, although he had not imbibed. The fundus of both eyes revealed great capillary congestion, but no hemorrhages. His arteries were apparently sclerotic, and left ventricle of the heart hypertrophied. There were no valvular lesions, but the second sound (aortic) was unduly accentuated. His most prominent complaints were:

1. Headache. This symptom began eight months ago, lasting at first from a few hours to two or three days; migraine in character. With the lapse of time the headache became more and more severe and persistent until finally it was constant.

2. Dizziness. For several years dizzy spells would come over him occasionally, but since the onset of the severe headache this symptom became more frequent and troublesome.

3. Vomiting, nausea, retching and sometimes diarrhea were gastrointestinal disturbances which accompanied the severest attacks of headache.

4. Frequent urination. During the daytime he urinated about every hour; could not often go two hours with comfort, and at night he urinated four or five times. Lately he has had tenesmus at the neck of the bladder after micturition (septic deep urethra).

5. Loss of strength. His strength began to fail three years ago, and since then he has lost about twenty pounds. Since the headache has become so marked, he has not been able to earn a living with his head or hands.

6. Nervousness. Feeling miserable, sometimes drowsy and again wakeful. Between the attacks of headache, he felt a soreness through his brain, which prevented him from inclinations to thinking or talking. There has been some pain and tenderness in the region of his kidneys for several years, but lately this symptom was overshadowed by those already mentioned.

7. Coma once. One week before he entered the hospital he became unconscious and remained in that condition for three or four hours. The coma followed one of his severe headaches. No convulsions occurred. He was in the hospital one week before I operated, which made it sixteen days after the occurrence of the coma. While the symptoms of this disease are varied and often insidious, making a diagnosis sometimes difficult, the few symptoms and signs I have already mentioned, even without telling about his urine, point to but one condition—interstitial nephritis.

Urine Before Operation.—Quantity, 72 ounces in twenty-four hours. Pale amber color; sp. gr., 1007; urea ¾ of 1 per cent.; albumin, 36 per cent.; pus cells; epithelium; casts, both hyaline and granular.

Operation (Nov. 23, 1903).—Chloroform was administered. A skin incision was made parallel to and half an inch below the twelfth rib on each side. The kidneys were then reached by splitting the muscles and dragging out the fat with forceps, which brought the kidney into view. The capsule was split over the cortex and peeled off. The right kidney was smaller and firmer than normal; the perinephritic fat was more vascular and fibrous than normal and firmly adhered to the kidney, and the capsule was thickened and firmly adherent to the cortex of the kidney. In stripping it off, small portions of kidney broke off with it in several places. While no effort was made to save the capsule from injury, still the major portion of it was left as a collar around the root of the kidney. The surface of the kidney was darkish-red in color, which bled rather freely, and also from multiple punctures. A V-shaped section was removed for microscopic study; from this wound arterial blood spurted from a small arteriole. A mattress suture of fine catgut controlled it. The fat was now displaced below the organ, the wound closed, and drainage of gauze and tube inserted to the surface of the kidney.

The left kidney was not so pathologic in appearance, its surrounding fat and capsule not so thick and fibrous. On peeling off the capsule no bleeding occurred similar to that on the other side. A section of kidney tissue was removed.

Urine After the Operation.—For three days blood was present in the urine. The quantity passed in twenty-four hours varied from fifty-six to sixty-six ounces. The urine of the fourth day had a specific gravity of 1010; 20 per cent. albumin; urea, 1 per cent., and it also contained hyaline and granular casts; pus, which was from deep urethra. Several examinations of it since then have shown no material change, and I expect to find albumin and casts for several weeks. In some cases the improvement in the urine is most remarkable, the albumin and casts disappearing between three and six weeks.

Microscopic Report of Renal Tissue Marked R. and L. (from the P. and S. Laboratory).—One (R.) was from the right kidney and the other (L.) from the left. The changes in both were characteristic of chronic interstitial inflammation. There was increase of fibrous tissue throughout the sections, forming concentric layers about the tubules and Bowman's capsule, with some round-cell infiltration. In the selection from the right kidney there was complete atrophy of some of the glomeruli, represented by densely encapsulated hyaline masses. In no instance were the tufts and capsule normal, there being thickening and increase in the number of cells. The convoluted tubes showed hyaline, granular and fatty changes. Epithelial débris and tube-casts. Where the connective tissue was most abundant, the tubules were atrophied, and represented by cubical cells. A few of them were dilated.

Result.—The immediate result in this case is simply marvelous. The clinical picture is completely changed. Before the operation he was suffering with uremia, which was manifested by the headache, dizziness, vomiting and nervous disturbances; even a coma on one occasion. All his symptoms vanished within a week. His mind cleared up; sight completely restored and appetite returned. No headache, restless nights, vomiting nor pain in the back now. The appearance of the man has changed completely. The swelling and edema of his face, hands and lower extremities have disappeared. He looks happy, and says that he never felt better in his life.

CASE 3.—Same clinic. *Chronic Parenchymatous Nephritis. Double Decapsulation. Death.*—The case I operated on a week ago died on the third day from pulmonary edema. You will recollect that I gave a bad prognosis just as soon as I saw his kidneys. He was a young man, 18 years of age; had scarlet fever twelve years ago, but his nephritis was not discovered until nine months ago.

Condition on Admission (Nov. 13, 1903).—There was general edema all over the body. Face puffy, cellular tissue around the eyes filled with serum; scrotum slightly edematous; vision very bad, could not count fingers nor distinguish his mother from the nurse. He complained of "spots before his eyes" (fundus not examined), headache, indigestion, nausea, vomiting, frequent urination and a small quantity each time, backache and tenderness over the kidneys. Slight difficulty in breathing and occasional spasms of his muscles of the right arm. He was evidently verging on uremic convulsions.

Urine Before Operation.—In twenty-four hours twenty to thirty-six ounces. Quantity decreasing. Specific gravity, 1010. Pale, bad odor, acid; albumin, 35 per cent.; urea, 1 per cent.; hyaline and granular casts.

Operation (Nov. 13, 1903).—Chloroform throughout. Double decapsulation at one sitting, double nephrotomy and drainage. The first stroke of the knife through the skin and fat was followed by rapid oozing of clear serum. During the entire operation it kept one assistant busy mopping it up. The fat around the kidneys was water-logged, the capsules thin and insignificant, the organs themselves very small, pale and bloodless. Each kidney was about one-third the size of a normal one. On passing the knife into the pelvis of each no bleeding whatever occurred, which was a bad sign. In this case I forgot to remove a section of the kidney tissue until it was too late. It was so clearly a case of "small white kidney," parenchymatous nephritis in its clinical history, symptoms, signs and microscopic findings in the urine, that I feel satisfied with our diagnosis. He stood the operation well.

Urine After Operation.—First twenty-four hours eighteen ounces voided by bladder and dressings were soaked several times. Second twenty-four hours twelve ounces voided by bladder and dressings soaked three or four times. Bowels began to move rapidly and urine was not collected on third day, but the kidneys were secreting all the time.

Result.—Death at the end of three days from edema of the lungs. This young man had received from internists all the skill and medication that this city can afford. It was of no avail. Inasmuch as the exact condition of the kidneys could not be accurately known by the findings in the urine or symptoms and signs, I decided to offer him the only chance left for a respite from his nephritis. Considering that his kidneys were so extremely small ("small white") and in an advanced pathologic state, it is a surprise that the chloroform and operation did not put them completely out of commission. His kidneys secreted urine to the last.

INDICATIONS FOR SURGICAL TREATMENT.

1. *Floating Kidney.*—Floating kidney may now be put down as one of the indications for decapsulation. An observation, no doubt a common one, is that a floating kidney is often accidentally discovered in one's own person, or is found by a physician, at a time when no disturbing symptoms are present from it. It is made light of and often forgotten until some day it gets painful and tender, the urine becomes irregular in flow, sometimes scant and again profuse albumin appears in it; urea decreases; cylindroids are observed and the general health is being undermined. In a nervous person the pain might be suggestive in origin, but the urinary changes never. During the last six years I have held the view that a floating kidney should not be operated on simply because it was dislocated. I therefore refused to operate on other than those giving disturbance. I have learned that several of those whom I advised to have no surgical interference came under the knife of some other surgeon. I made inquiries of thirteen widely-scattered cases, and all but three had undergone an operation because of the painful and annoying symptoms instituted by the floating kidneys.

On the other hand, a freely movable kidney may be diseased without causing pain and tenderness, or even constant urinary changes. This experience and knowledge have convinced me that all cases of floating kidneys should be treated by decapsulation and fixation. I firmly maintain also that the surgeon's work is not complete without a microscopic examination of a piece from the kidney. It is surprising how often you find the unexpected—chronic nephritis.

2. *Nephritis and Floating Kidney.*—It has been maintained that cases of floating kidney with the symptoms and signs so characteristic of nephritis are not cases of nephritis at all, but that the condition is temporary, the symptoms disappearing in due time after nephropexy. The only way to refute such a statement is to exhibit under the microscope sections of the kidney of the cases in question. The immediate result in this class of cases has been so amazingly prompt, and the remote results so permanent, that some surgeons doubt these to have been cases of nephritis.

It is a matter of common clinical experience to find that nephritis does not always find expression in the urine, and the data from it are often unreliable in forming an idea of the severity of the disease. Inasmuch as I could not produce better cases than the first two cases from which kidney tissue was removed to impress the importance of the microscopic examination, I am constrained to reproduce the reports, which are as follows:

Pathologic Examination.—(Klebs' Pathological Laboratory.) The section of kidney from the case of Mrs. M., sent to the laboratory Jan. 4, 1899, presents the following changes: The connective tissue growth is not extensive, the lining epithelium of the tubes is more implicated, as in chronic parenchymatous nephritis. The lining epithelium of the convoluted tubules shows cloudy swelling, and there is some small cell infiltration in some parts of the kidney, indicating that the inflammatory process is still existing. The epithelia of the glomeruli are nearly lost, some of the glomeruli consisting only of a homogeneous mass. Capsules of Bowman thickened; tubules with atrophic epithelium present, dilated tubules, desquamated epithelium in some of them, hyperplastic connective tissue around others. Pathologic diagnosis: Interstitial nephritis with cloudy swelling.

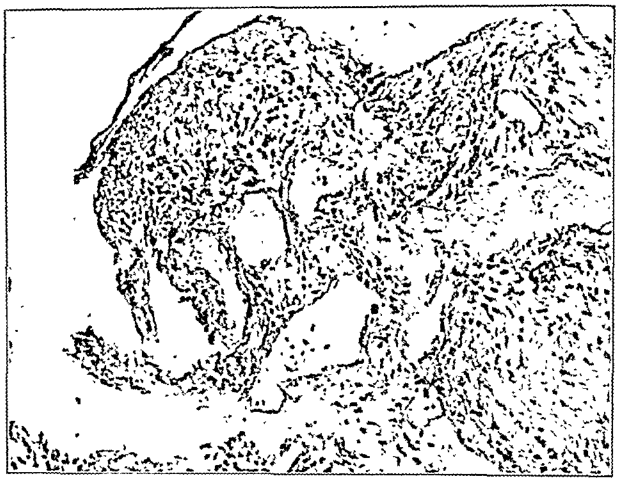

Figure 1.

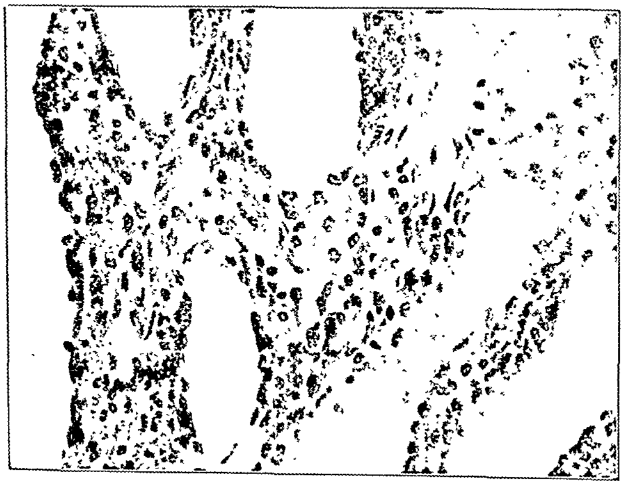

Figure 2.

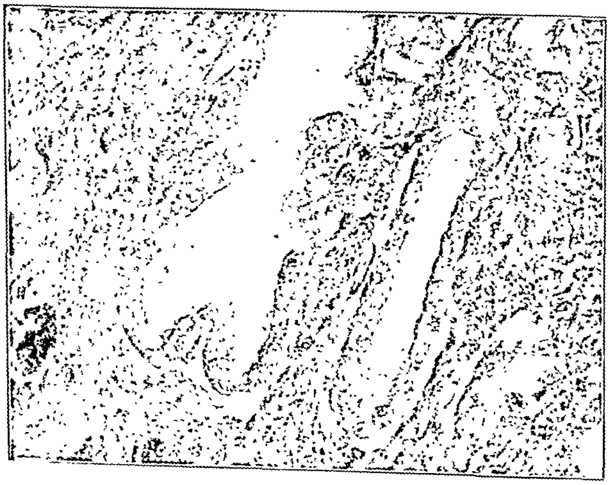

Figure 3.

The above pathology is represented by microphotographs Nos. 1, 2, 3 (Zeit). The second case from which kidney tissue was removed and studied Zeit furnished the following report:

The section of kidney from the case of Mrs. W., examined Jan. 14, 1899, shows the picture of an interstitial nephritis with much proliferation and hyperplasia of connective tissue, areas of which consist entirely of this connective tissue growth, with obliterated or waxy glomeruli. Between these portions

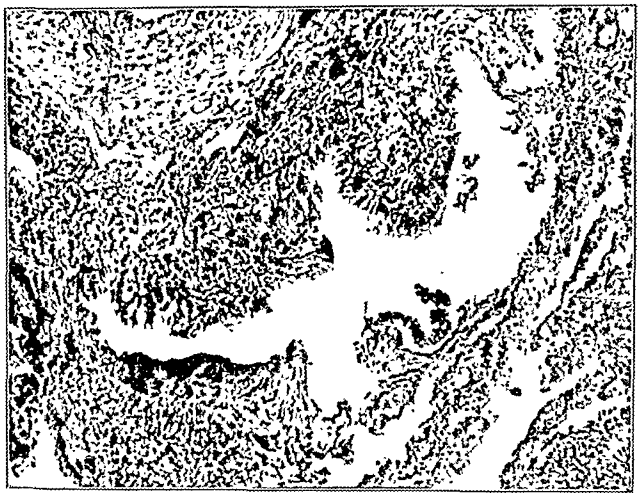

Figure 4.

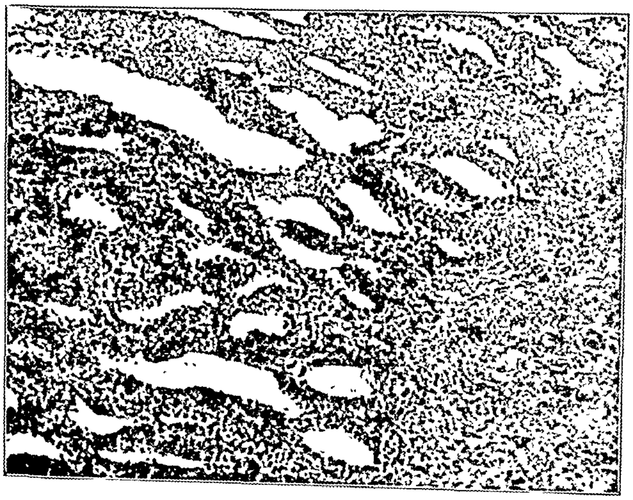

Figure 5.

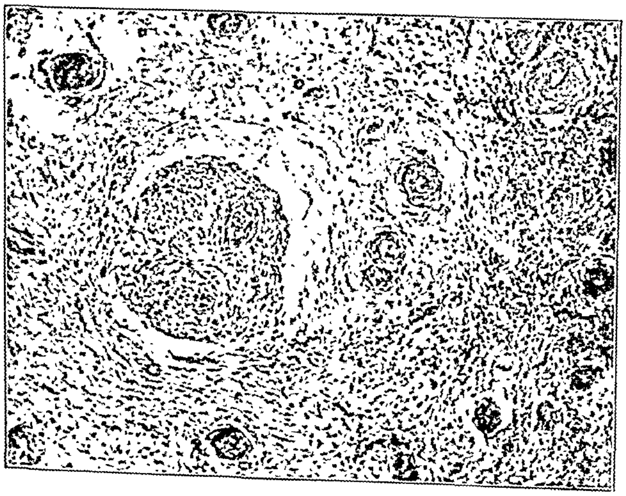

Figure 6.

are found islands of partially changed kidney tissue, in which there are atrophic tubules and tubules with a desquamated epithelium, flattened epithelial lining in tubules of diminished caliber, and some cloudy swelling in the lining of the epithelial cells. In some of the tubules hyaline casts are found. The capsules of glomeruli are thickened, and their connective tissue with many nuclei is arranged in concentric layers.

These changes are represented by microphotographs Nos. 4, 5 and 6 (Zeit). These microphotographs speak for themselves and are produced for the first time, to put at rest whatever misgivings may have been expressed regarding the pathologic findings in those cases.

In reply to the statement that the cures were so rapid that they could not have been true cases of nephritis, it is, I must say, almost incredible that the clinical picture of one in suffering and distress can, within a few days, by a simple operation, be transformed to represent ease and happiness, but it is just as true as it is that most of the tender floating kidneys are true cases of nephritis, as demonstrated microscopically. It is equally hard to believe that within a few weeks or months the symptoms and signs of the nephritis clear up. We must remember that the kidneys have an abundant vascular supply, excretory tubes and glomeruli, more than enough to carry on their ordinary functions, and a recuperative and regenerative power that is most wonderful. With the knowledge that we possess of the rapid subsidence of acute, subacute and chronic inflammations of other organs, and parts of the body, when properly treated, we should no longer doubt the rapid cure of kidney inflammation when given the best opportunity to flush itself of poisonous materials through its natural system of drainage, and also allow blood serum and urine to drain through punctures made in it. Nature repairs the traumatism made in reaching the kidney wonderfully rapidly, and why not as speedily restore the kidney to assume its function and cease supplying albumin, casts, etc., to the urine? In tender and floating kidneys the fact that a small portion of the organ is removed, and that we find it diseased, is no proof that the whole kidney is in the same pathologic condition. In sections from floating kidneys there are sometimes only slight changes, while again all the characteristic destructive changes of advanced nephritis are present. It is my firm belief that a floating kidney is a frequent cause of chronic nephritis, by constantly interfering with its vascular supply, nutrition and free excretion of urine.

3. *Nephritis.*—*a.* Acute Bright's disease. *b.* Chronic interstitial (Bright). *c.* Chronic parenchymatous (Bright).

Mr. Reginald Harrison boldly and successfully attacked acute diffuse nephritis under a mistaken diagnosis, but nevertheless originated the splitting of the capsule to relieve kidney tension, and has written fully concerning his cases. Whether acute Bright's disease be due to exposure to cold and wet, accompanies or follows specific fevers, or is caused by toxic agents or pregnancy, it would seem rational not to allow the patient to speedily die without following the example of Harrison.

GENERAL REMARKS.

In looking over the literature I find that the causes of death after the operation in 123 cases, by different surgeons, were as follows: Four died of pulmonary edema, 6 of uremia, 4 of coma, 3 of sudden heart failure, 3 of exhaustion, and one each of endocarditis, suppression of urine (ether being given), anuria, general dropsy, collapse, pleuritic effusion and myocardial thrombosis. There were 27 deaths out of 123 cases, within a year after the operation. A closer analysis shows that of these 27 deaths, 6 died within eighteen hours after the operation, 9 between one and nineteen days, 2 between two and seven weeks, 3 between two and three months, and 1 lived a year. The vast majority of these deaths must not be attributed to the operation. Even allowing all deaths within a week to be due to the operation, there would be a mortality of only about 9 per cent. When the limitations of the operation are more clearly defined, and many of the extreme cases left alone, the mortality should not be more than 5 per cent. in the hands of experienced surgeons. It is fair to conclude that the earlier an operation is performed in these cases the less will be the fatality, and the greater the benefits.

THE CORRECTION OF RETRODISPLACEMENTS OF THE UTERUS.*

CHARLES W. OVIATT, M.D.
Surgeon-in-Chief to St. Mary's Hospital.
OSHKOSH, WIS.

It is unnecessary to occupy your valuable time by going extensively into theories advanced as to the etiology of retrodisplacements of the uterus, or discuss the almost endless train of subjective symptoms that have been attributed to this condition. Nor shall I attempt to trace the evolution of the treatment from the time of Hodge down through the operative measures that have been devised during the last decade. This is history with which you are all familiar.

The uterus, bladder and rectum have their physiologic range of motion, and must remain susceptible of motion to perform their functions normally. This being true, there can be no fixed axis of the uterus while it retains its normal relation to the other pelvic organs. Simultaneously with retrodeviation beyond the normal limit of motion, there is a descent of the organ toward the pelvic outlet, with a change of its relation to surrounding viscera, as well as corresponding changes in its blood supply and drainage of its secretions. With pre-existing or subsequent pelvic inflammation, the uterus and adnexæ become fixed in mal position.

It is perhaps the most generally accepted opinion that labor and abortion are the chief etiological factors in the production of retrodisplacements. While we know that damage to the integrity of the pelvic floor with an infected and heavy uterus frequently acts as a cause, we know equally well that it does not always do so. We encounter at the examining table cases of extensive lacerations with heavy, subinvoluted uteri, in which the axis of the organ is normal. On the other hand, we find cases of extreme retrodeviation in young girls and unmarried women in whom the uterus may be almost infantile in type, perhaps fixed by adhesions. A study of the clinical history of many of these cases will show tubal and pelvic inflammation to have existed. Congenital retrodisplacement is extremely rare.

The consensus of opinion of those who have had the richest experience seems to be that simple, uncomplicated retrodisplacements rarely give rise to disturbing symptoms, and when they coexist they are caused, in large part at least, by other pathologic conditions. No treatment, therefore, should be suggested until a careful examination reveals the relation between the possible causes of the symptoms and the retrodisplacement. To this end, general anesthesia for examination may be necessary. Nothing should be overlooked or taken for granted. We should not be content when we find distended and adherent tubes or a prolapsed and tender ovary, but should explore the rectum for hemorrhoids or fissure, which, as we all know, may give rise to symptoms closely simulating those derived from pathologic conditions within the pelvis.

---

* Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver, Dec. 28-29, 1903.

In the few uncomplicated cases, implying a uterus movable and free from inflammation, but which gives rise to discomfort either psychic or real, the use of a well-fitting pessary in connection, if necessary, with pelvic massage and postural treatment, may be all that is required.

With the advances made by modern, aggressive surgery, the use of the pessary was all but abandoned; there seems to be of late, however, a wave of sentiment back toward its more frequent employment, which possibly will increase as we learn to differentiate our cases more carefully. After the selection of the proper case for its use, the most serious objection to it is the time required to accomplish a permanent result. Its use implies a patient having the leisure and means which will enable her to be "tied to a doctor's office" for months or years. The same condition occurring in a woman who is obliged to work, standing on her feet many hours each day, demands something different, as she can not afford the protracted treatment of her (perhaps) more fortunate sister. In her case measures must be employed which will restore to her in the least possible time the ability to work comfortably. This, of course, means an operation. Many operations have been devised, the great number being the strongest evidence of their shortcomings. The chief source of failure and disappointment that has attended these operations has probably come from the belief that it was the position of the uterus *per se* that gave rise to symptoms demanding treatment, instead of the coincident pelvic lesions that accompany it. Dysmenorrhea is not an infrequent accompaniment, but is rarely caused by it, and is, therefore, almost never relieved by the correction of the displacement, either by mechanical treatment or operation. When this is the chief symptom complained of, it is wise to be guarded in promising relief.

The organ has been attacked from above and from below; its natural ligaments shortened and new ones made with the central idea of correcting its abnormal axis. With the clearer understanding of pelvic pathology in connection with these cases, I think we may safely look for better results in the cases we operate on, and in our choice of a method one will be selected that enables us to deal with all possible complications.

Of the many operations devised, the ventrosuspension of Kelly and Olshausen and the extraperitoneal shortening of the round ligaments after the Alexander-Adams method, or some modification of the same, are still the operations in most common use. The vaginal methods of Duhrssen, Mackenrodt and others have not found especial favor on this side of the Atlantic. That ventrosuspension still serves a useful purpose is evidenced by the fact that it is advocated by some of the ablest members of the profession. In doing it, one is enabled to deal with all intrapelvic complications, and it is probably chiefly for this reason that it has held its own against the extraperitoneal methods, notwithstanding the fact that it drags a pelvic organ into the abdomen and creates a source of potential danger that is recognized by all.

The Alexander-Adams operation is applicable only to cases in which the uterus is freely movable and free from pelvic complications. In other words, its application is confined largely to cases where it is least needed and where it can be of the least benefit.

The same argument, I think, obtains, although perhaps to a less degree, to operations done for this condition through the vagina. The advocates of this route insist that they are able to deal as thoroughly with any possible complications found within the pelvis, as through a suprapubic opening. This position, I feel quite sure, will never be accepted by the majority of operators. The slight advantage claimed for the vaginal route can hardly offset its palpable disadvantages. While ready to grant that the majority of cases may be successfully operated on by some method through the vagina, it is certainly true that with tubal infection that has created a mass of matted adhesions involving, perhaps, intestines, or the vermiform appendix, better, cleaner and safer work can be done from above.

The majority of cases require the careful use of the curette as a preliminary step, as endometritis is a common complication. If the cervix is lacerated and hypertrophic, it should be repaired or amputated. Lesions of the pelvic floor should, of course, be repaired. Whatever the operation selected, it should permit of thorough intra-pelvic work, and should be one that restores the normal axis of the uterus, at the same time leaving it free to adapt itself to its normal range of motion. The operation I am about to describe meets these requirements. It was devised by Dr. George H. Noble of Atlanta, and brought out by him in a paper entitled "Intramural Extraperitoneal Anchorage of the Round Ligament for Posterior Displacement of the Uterus." This paper was read before the Southern Surgical and Gynecological Association at its meeting held in Cincinnati last year. In describing the technic I can do no better than to quote freely from Dr. Noble's paper:[1]

"1. A transverse incision is made through the skin, fascia, fat and aponeurosis down to the recti muscles. This incision, in the ordinary subject, should be about 1½ inches above the pubis, and should extend laterally to the outer border of the recti. The recti are separated vertically in the median line and the peritoneum opened in the same direction. The pelvis is investigated, proper attention given to the local pathological conditions, and the uterus raised.

"2. A pair of light compression forceps with teeth in the end (Senn's) is passed through the abdominal opening, and grasps one of the round ligaments about the middle of its intraperitoneal portion. By traction on the forceps the uterus is pulled somewhat to the side of the pelvis which is opposite the ligament held, the peritoneum is drawn away from the region of the internal abdominal ring, and the ligament made taut so that it may be the more readily recognized in the extraperitoneal manipulations to follow.

"3. Now just beyond the outer edge of the rectus, at the end of the transverse incision, the point of a pair of artery forceps is thrust through the posterior sheath of the muscles, but does not enter the abdomen. The forceps is opened and withdrawn, so that an aperture large enough to admit the index finger is left. The finger is introduced through this opening in the preperitoneal fat, and feels the round ligament without difficulty, for it is brought into prominence by tension on the forceps which holds its uterine end.

"4. The finger, passed through the opening just described, is hooked under the extraperitoneal portion of the ligament from below upward, and draws it up into the wound. The sheath of the ligament is then split open by blunt dissection. The sheath and the peritoneum are stripped back in the direction of the uterus, completely divesting the ligament of its covering. It is then drawn out of the wound, and forceps slipped underneath retains it until the opposite ligament is raised and denuded in the same way. If the uterus has been in a state of marked retroversion, the ligaments will have become so attenuated as to allow their approximation in the median line in front of the recti, which approximation will restore the uterus to its normal position.

---

[1] Transactions Southern Surgical and Gynecological Association, 1902, p. 217.

"5. When it has been determined that the ligaments are long enough to meet in the median line they are each left looped over forceps, while the peritoneum of the median incision and the recti muscles are closed with continuous kangaroo or catgut sutures.

"6. The ligaments are next approximated in front of the recti and tied together.

"7. Now, beginning in one angle of the transverse incision, the cut edges of the aponeurosis are stitched together with a continuous kangaroo suture. When one or two loops of the suture have been passed, the needle, in crossing the interval between the two edges, is made to pass through the ligament. It is well also to pick up a little of the muscle on each side of the ligament in order to provide against dead spaces. This process is continued as each successive loop is passed until the center of the incision is reached, when the free end of the suture is clamped and left long. Starting in the other angle of the transverse incision (but looping in a contrary direction, so that when the two sutures meet their free ends may be on opposite sides of the wound), a second strand of kangaroo unites the edges of the aponeurosis on that side and picks up the round ligament and adjacent portions of the muscles as before. The kangaroo tendons are tied together, and the ligaments are thus embedded and firmly anchored between the aponeurosis and muscles.

"8. The structures in front of the aponeurosis are closed in the usual manner."

The advantages of the operation may be stated as follows:

There is but one incision and through it any pelvic complication may be treated.

The operation utilizes the strongest part of the round ligament instead of its distal end. The normal mobility of the uterus is not disturbed, and it is left in the pelvis where it belongs.

It causes no vesical irritation or dysuria if the ligaments are not embedded too low down, and no dragging if they are not brought through too high up.

The anchorage is superior in permanency to all peritoneal attachments; the uterine portion of the ligament will not stretch away.

There are no sutures in fundus to irritate the uterus.

The fixation is extraperitoneal; no irritated point invites subsequent adhesions to abdominal viscera.

The peritoneal investment of the ligament is not drawn into the abdominal walls, producing funnel-shaped depressions and inviting hernia.

It does not interfere with the physiological development of the uterus during pregnancy.

During the last year I have made this operation 23 In all but 3 there were intrapelvic or other com- 9 s. In 10 the appendix vermiformis was remov- week cause of a history of definite recurring attacks of appendicitis, or because from its appearance it was deemed wise to remove it. In one case a broad ligament cyst was removed, and in several diseased appendages were taken out. These are mentioned merely to show that there is no difficulty in doing any necessary intrapelvic work through the transverse incision and separation of the recti muscles. In all the cases local office treatment by means of tampons or pessaries had been resorted to without relief. Most of the cases were in women who are obliged to work, and who preferred to undergo an operation rather than submit to further treatment. The three uncomplicated cases were marked neurasthenics with dysmenorrhea. While the displacement remains corrected, there has yet been no improvement in the dysmenorrhea, and little or none in their general condition. There were no deaths or serious complications following these operations. So far as I have been able to follow the cases the results have been all that could be expected.

THE SURGICAL RELATION OF THE VERMIFORM APPENDIX TO PERFORATION IN TYPHOID FEVER.

LEVI JAY HAMMOND, M.D.
PHILADELPHIA.

To within a few years, perforation in typhoid fever and its well-nigh fatal consequence, perforative peritonitis, were regarded as complications beyond hope of relief by surgical intervention, until E. Leyden.[1] in 1884, recommended surgical repair as a rational procedure, likening the condition to suppurative pleuritis. Later in the same year, Mikulicz[2] reported three cases of his own, in addition to reviewing the cases previously recorded in literature. In 1886, Dr. J. C. Wilson[3] remarked: "The courage to perform laparotomy at this time will come of the knowledge that the only alternative is the patient's death."

Encouraged by these bold advocates, surgeons throughout the world have frequently reported operations for this heretofore fatal complication, even in the face of so high mortality as 80.64 per cent. (Keen), 73.78 per cent. (Finney) and 88 per cent. (Monad). Yet when we contrast with the above the mortality of 95 per cent. (Harvey Cushing) in cases unoperated on, it gives a sufficient margin to encourage the undertaking.

Our efforts will probably not be crowned with greater success until the clinician can determine the time of rupture in a given case, or the pre-perforative stage as pointed out by Cushing. The greatest possibilities, however, seem to lie in the removal of conditions that would predispose toward perforation.

The prophylaxis, therefore, in perforative peritonitis from typhoid fever is the pivot on which every effort should revolve, until either the cause is removed or accuracy in diagnosis has enabled the clinician to recognize the pre-perforative stage, as prompt interference after perforation has taken place has not evidenced any marked lowering in the mortality table, as shown by analysis of cases recorded by Finney, Cushing, Keen and others.

The appendix vermiformis is the seat of perforation in typhoid fever, according to Cushing, in 9.6 per cent.

[3] Phila. Medical Times, Dec. 11, 1886.

of all cases of perforation; according to Fitz, in 3 per cent. of 167 cases; and according to Hopfenhausen, in 7 per cent. of 108 cases. According to Osler, Fitz, Murchison and others, perforation occurs in 3 per cent. of all cases of typhoid fever. It is the cause of death in from 6 to 7 per cent. of all fatal cases. The ileum, according to Finney, is the seat of perforation in 80 per cent., large intestine in 12 per cent., and the appendix in 5 per cent.

It is especially in this 5 per cent. of appendiceal perforations in typhoid fever that the author is interested; first, because of the belief that in addition to the 5 per cent. of perforations in typhoid cases arising from the appendix alone, there is a large number of cases occurring in the ileum and ascending colon that can be directly traced to pre-existing disease of the vermiform appendix, and in support of this belief, the following cases seem to bear witness:

Case 1.—(March, 1903.) A woman, 26 years of age, a member of a religious order, had been stricken with typhoid fever two weeks before symptoms of perforation of the bowel presented themselves to her attending physician; there had been, however, from the very onset of the disease, in addition to headache, backache and an extensive degree of nervousness, much pain to the right of the hypogastric region, associated with early and continued abdominal tympany; liver dullness was absent, splenic dullness increased.

When seen in consultation on the fifteenth day of the disease, she complained bitterly of severe and constant abdominal pain, especially in the right iliac region, constant nausea and some vomiting; pulse 140, temperature 100. The pulse rate from the beginning of her illness had been unusually high, the chart showing it at no time less than 120. The temperature, which at this time was 100, had ranged during the previous two weeks between 102.2 in the morning to 105, the highest in the afternoon. The pinched expression was pronounced and the patient in every way showed evidence of great illness. The point of greatest tenderness was just above and to the right of the pubes. Blood count at this time showed leucocytes to be 11,000. The patient was again seen four hours later, and a second blood count made, showing leucocytosis 14,000. Operation was at once advised.

Operation.—Under ether anesthesia, an incision five inches in length was made along the outer border of the right rectus muscle. The abdomen was found filled with gas and a large quantity of chocolate-colored fluid mixed with feces that the exudate had made no attempt at walling off. The opening in the bowel was readily found because of its great extent, in the ileum about 10 to 12 centimeters from the valve. The rent in the bowel involved nearly the entire lumen transverse to its long axis. The ileum and several inches of the ascending colon were firmly anchored by well-organized adhesions, evidently of long standing. The appendix could not be brought into the incision because of this firm anchorage of itself and the colon to the outer parietal wall.

The rent in the bowel was closed by means of the Czerny-Lembert sutures, the abdomen flushed with normal salt solution and afterward dried by means of sterile gauze mopping. Plain sterile gauze was packed about the sutured bowel and brought out through the incision, the remainder of it being closed.

Notwithstanding the extreme condition of the patient before, and at the time of operation, she seemed to stand it well, and if anything, somewhat rallied from it. There was certainly at least no pronounced shock following the operation; there was not any pronounced improvement, however, and the patient died sixty hours later.

Autopsy.—Anatomic diagnosis: Perforation of the ileum about 12 centimeters above the ileocecal valve, involving the entire bowel. The deep sutures had held firmly while the Lembert sutures showed that they had been dragged on by some tension which had been exerted on them. Agglutination of the coils of the ileum existed throughout most of the lower right side. The appendix was cicatricial to near its distal extremity, where it was firmly adherent to the lateral wall of the parietal peritoneum. It derived its nutrition entirely from this source. The colon was also firmly bound down. The position occupied by the appendix showed clearly the tension that it had exerted on the closed wound in the ileum; there had been, however, no escape of the contents of the bowel into the general parietal cavity after operation. The adhesions found between the coils of the intestines and also those about the appendix and colon were so firmly organized that they could not have occurred from the appendicitis in this instance.

In going over the earlier history of the patient, I find that she had suffered for some time from dull aching in the right side, though never any decided pain, often extending down the right leg, with spells of nausea, occasional vomiting and obstinate constipation; in other words, a very clear history of an insidious appendicitis.

Case 2.—(October, 1903). A woman, 22 years of age, married. Was seen in consultation on the fifth day of her illness, which was thought by her attending physician to be typhoid fever, though somewhat in doubt because of the history of an attack of appendicitis, mild in type, some months previous. In the beginning the patient had a chill with headache, backache and some epistaxis. The abdomen was somewhat tympanitic, liver dullness absent and splenic alteration could not be detected. There were considerable pain, which was constant, and marked tenderness on the slightest pressure in the right iliac region, extending up as high as the costal cartilages. There were constant nausea, anorexia and constipation; pulse 120; temperature, when I saw her at noon, 101.8. Previous to this temperature record showed a variance from 101 in the morning to 102.4 in the afternoon. On palpation rigidity was marked and an inflammatory mass could be distinctly felt in the region of the appendix. The tongue was coated with a dirty brown coating and flabby tooth-marked edges.

With the history of a previous attack, therefore almost certainly extensive adhesions, and with the undoubted presence of an acute attack now existing, I felt it was good counsel to advise immediate operation for the removal of the appendix, even in the face of a probably developing typhoid fever, recalling as I did, the clinical picture of the preceding case which I had seen but a few months before.

Operation.—On the seventh day of illness, under ether anesthesia, an incision was made 3½ inches in length directly over McBurney's point. After a search of several minutes an unusually short appendix with the center cicatricial was found embedded in an inflammatory mass behind the cecum. There was no pus present, though the intestines about the ileocecal region were intensely injected, and in several places there was agglutination of the coils of the ileum in the lower two feet. The mesentery glands seemed everywhere greatly enlarged and to the sense of touch so like the appendix that several times during the search they were brought out through the incision in mistake for the appendix. After taking much pains to break up all adhesions the incision was closed without drainage and the patient made an uneventful recovery. Stitches were removed on the tenth day.

The operation in no way interfered with the natural course of the fever from which she was suffering. Microscopic examination of a transverse section of the appendix showed a complete cicatricial obliteration of the lumen.

Blood count on the morning of the operation showed the number of white corpuscles 11,000. Positive diagnosis by the Widal reaction was made on the eighth day, or the day following operation. Temperature throughout the illness showed the highest reached in the afternoon, 103.8, morning temperature 102. The pulse ranged between 100 and 116. The entire course of the disease was characterized by constipation, it being necessary to use enemas whenever bowel movements were secured.

While the pathologic condition found in these two cases does not give the whole truth, it certainly goes far toward presenting a clew along the lines of prophylaxis in perforative peritonitis.

I am thoroughly convinced that in Case 1 the function of the bowel was so impaired by adhesions, not only of the coils of the ileum to each other, but the tension caused by adhesion of the appendix to the lateral parietal peritoneum, which favored solution in the continuity of the bowel at the point of ulceration at the site of Peyer's patches, was entirely responsible for the tremendous rent that took place. This was demonstrable at the postmortem, which showed the great amount of tension on the superficial sutures.

In Case 2, the only interpretation that could be placed on the extensive adhesions, so like those found in Case 1, is that a like result should have been expected. The inflammatory exudate, which takes place after every attack of appendicitis, it matters not how mild the type, is certain to impair to a degree the function of the bowel, not only immediately about the ileocecal region, but often extending over a considerable extent of the ileum disarranging the circulation, and in this way bringing about structural change in the bowel, interfering as well with the fecal current, and together serving as a most potent factor in the production of perforation.

Where the appendix has once been the seat of inflammatory change, a disease like typhoid fever is sure to light up a recurrence, and as at best its powers of resistance are poor, it could hardly be expected to escape rupture within the organ itself, or what would seem more often to take place, rupture of a Peyer's patch, which, if not actually caused by impairment of the function due to pre-existing disease in the appendix, may be regarded as at least favoring it. Not only do the two cases here reported bear out this belief, but many of those recorded, notably two of Osler's cases; one on admission had an inflammatory mass the size of a walnut in the appendix region, subsequently dying from perforation in the ileum, while the other at the autopsy showed perforation of the ileocecal region and the appendix embedded in an inflammatory mass. One of Hare's two cases also showed pre-existing disease in the appendix. Indeed, proof of pre-existing disease in the appendix in cases of perforation in typhoid fever is not wanting if careful analysis be made of the literature on the subject. Toft says that from personal investigation of 300 cases of illness of all sorts, every third person between the ages of 20 and 70, showed evidence of present or past traces of inflammation of the appendix, and that actual structural change existed in 5 per cent. of all bodies examined. Kraussald declares that this percentage is rather too low than too high.

If these percentages can be considered as accurate, it is within the power of the surgeon to reduce the mortality in perforative peritonitis in typhoid fever from 80 per cent. to 73, first by eliminating the appendix as a factor *per se;* second, by freeing the agglutinated intestines from adhesions caused by previous attacks of appendicitis, which afford possibility of still further serving as prophylaxis against occurrence of perforation in the ileum. Most observers agree that acute appendicitis, occurring during the course of typhoid fever, is merely a coincidence, and is probably in no instance the result of the bacillus of Eberth, nor to the general infective process resulting from the fever.

Hopfenhausen[4] shows in a study of thirty appendices removed from typhoid subjects dying from either asthenia or toxemia, that no special change existed in the appendix further than slight cellular infiltration, in no way sufficient to interfere with the function of the organ, and only that change that would be found anywhere in the intestinal tract that is supplied with lymphoid tissue. The type of appendicitis, therefore, that may be looked for during the course of typhoid fever, will usually be the recurrent.

Clinicians are generally agreed that the opinion formerly held of doubting the existence of typhoid fever where bowel symptoms were absent, is entirely erroneous, and as a matter of fact, bowel lesions are, if the bowel be previously healthy, rather atypical than typical symptoms at the onset of the disease.

With this knowledge in mind, when a case of typhoid fever presents among its earliest symptoms pain to the right of the hypogastric region with tenderness, nausea or vomiting, aching or discomfort in the groin, ofttimes extending down the leg, anorexia, and last but not least, rigidity of the right rectus muscle, a relighting up of a pre-existing disease should be suspected, knowing, as we now do, that the right iliac fossa is not tender early in typhoid fever; at least not until after the seventh or eighth day, when the bacillus of Eberth is deposited in the glands of the intestines (Peyer's patches), Immediate laparotomy would seem the only wise course to pursue, removing not only the appendix, but thoroughly freeing the agglutinated coils of the ileum from its tied-down position, which must of necessity impair nutrition of the parts, and consequently diminish its structural resistence.

Dieulafoy states that if an appendicitis exists, the course of the fever will be higher early in the disease, and it may also be inferred that the morning drop in temperature will be less pronounced.

A study of the temperature and pulse in the cases recorded by Finney, Osler, Fitz, Cushing and others confirms this observation, especially in reference to the pulse, which is found to be continuously higher than is found in uncomplicated cases of typhoid fever.

THE ACTION OF MINERAL ACID ON THE CELLULAR SUBSTANCE OF BACILLUS TYPHOSUS.*

MAY WHEELER, Ph.D.,
Rockefeller Scholar in Hygiene in the University of Michigan.
ANN ARBOR, MICH.

This research was undertaken for the purpose of ascertaining whether or not the cellular substance of the typhoid bacillus shows any tendency to uniform and definite cleavage under the influence of the mineral acids, the ultimate object being to learn something of the chemical composition and structure of the molecule making up the substance of the cell. In this paper, which must be considered only a preliminary contribution, general results only are given, with the hope of being able to go more into detail subsequently.

METHODS.

The material used in these studies consisted of the cellular substance of a typical typhoid bacillus, which was obtained from the mesenteric glands after death from typhoid fever, and which gave in a typical manner all the characteristic cultural manifestations of this organism. The toxicity of the living culture was tested on rabbits, guinea-pigs and white rats, and then the rganism was grown on the large tanks used in this aboratory, and the germ substance obtained in suffiient quantity to carry out the investigations to be deailed later. The germ substance was washed with alohol, then placed in Soxhlet extractors and the fat horoughly removed with ether. After this extraction he cellular substance was ground in agate mortars and eparated from any traces of agar or other impurity by eing passed through fine meshed sieves. As thus obained, the cellular substance exists as a white powder hat is fatal to the lower animals when injected in susensions in water into the abdominal cavity in the proortion of 1 to 40,000 of body weight.

---

[4] Revue med. de la Suisse Romande, Feb. 20, 18.

* This and the following paper were in a series of studies of bacterial cells, research in the Hygienic Laboratory of the University of Michigan, 1903, read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology.

It has been suggested[1] that the intracellular toxins re not contained as such in the cells, but that they const of atomic groups or side chains of a more complex olecule. At any rate, to extract them, more active gents than mere solvents have been found necessary. n this research the action of a hydrolytic agent, namely, ilute sulphuric acid, has been tried. It was proposed find out whether or not this acid produced any defite cleavage—something as to the nature of the split oduct—whether it was a toxin, a protamin or someing else, and also to study the distribution of the nitrogen in the germ substance by aid of the action of the acid.

STUDY OF THE DETAILS OF CLEAVAGE.

First, acids of two different strengths were employed to determine whether or not the split product was affected by a variation in the strength of the acid. Two 10-gram samples of the powdered germ substance were extracted, one with 0.1 per cent. sulphuric acid, and the other with 1 per cent.; extractions being made in the cold first, then of the residue on a boiling water bath, at 110 C., and at 120 C. Extractions of these residues at 134 C. split off nothing further precipitable with the reagent used. The extracts were precipitated with three volumes of 95 per cent. alcohol, the precipitate filtered out, washed with alcohol, dried and powdered.

Two points of interest were observed, namely, that a definite cleavage seemed to take place in both cases, either the weaker or the stronger acid making the separation, and that in both cases the total amount of split product that could be obtained by extraction in this way was practically 1 gram, or 10 per cent. It is interesting to note in passing that two years ago, with the colon bacillus Vaughan obtained in one experiment, from the 50 grams of germ substance used, 5 grams of the substance split off with dilute sulphuric acid, and precipitated by alcohol,[2] which is 10 per cent., as found with the typhoid. The fact that treatment with acids of two different strengths yielded practically the same amounts of split product indicated that a certain definite cleavage had taken place. The figures for the amounts of split product are given in Table 1.

Table 1.—Results with Varied Strenth of Acid.

	0.1 per cent. H_2SO_4.	1 per cent. H_2SO_4.
Cold	0.2073	0.2015
Water bath	0.5427	0.6555
110° C.	0.1045	0.2215
120° (1 per cent. instead of 1/10 per cent.)	0.2290	0.0905
	1.0835	1.1690

In both cases no more was obtained by further extraction at a higher temperature, and while in the case of the series with 0.1 per cent. acid, a 1 per cent. acid was used for the extraction at 120; it is probable that several extractions with the 0.1 per cent. acid at that temperature would have accomplished the same result.

All these split products, as well as the final residue, were toxic for guinea-pigs, though not so toxic as the germ powder itself. It may be that the split products are not a single substance, but that they consist largely of some inert body with which the real toxin is mixed. The extracts all give the xanthoproteic test, also a fair Millon's, among the proteid color reactions, and those above 100, the biuret test.

From the 20 grams of germ powder used, there remained, after all extractions, a residue of 1.505 grams.

THE NATURE OF THE SPLIT PRODUCTS.

In order to investigate further the split products, a larger sample of germ substance was used, so that the yield might be greater, and in order to avoid as far as possible any decomposition of the split product by the acid, the weaker acid (0.1 per cent.) was chosen, since it seemed that by repeated extraction as much could be obtained as with the stronger acid. Accordingly, 200 grams of germ substance was extracted with 0.1 per cent. sulphuric acid in the cold, then the residue at 100 C. (flowing steam in the autoclave), and at 120 C. in the autoclave. The exact temperatures used for the smaller samples were found to be impracticable here, because with the larger amount, extraction on the water bath was not successful. Four liters of acid were used for each operation, and the extractions at a given temperature continued until no more was split off at that temperature, when the residue was again treated with acid, and extracted at the next higher temperature used. This required three extractions in the cold, four at 100 C. and two at 120 C. The amount of split product obtained by precipitating the extracts at each temperature with alcohol was the same relative proportion of the weight of the whole sample as the products obtained from extractions of the smaller samples, and the whole was approximately 20 grams, or 10 per cent., as before, the residue remaining this time amounting to 26.96 grams. The extracts each time were precipitated with three volumes of 95 per cent. alcohol, the precipitate after settling being filtered out, washed with alcohol, and then purified by dissolving, so far as possible, in water and reprecipitating with alcohol. In this way the split products were divided into a soluble and insoluble portion. The different soluble portions from each temperature were put together and repurified. The insoluble portions were saved except that at 100 C. This was very small in amount and so slimy and mucilaginous that it was not possible to remove it from the filter, and it was consequently lost. Determinations of ash, phosphorus and nitrogen were made in both the soluble and insoluble portions, and likewise in the final residue and original germ powder. First, the ash was determined, then the phosphorus in the ash. The nitrogen in each case was determined by the Kjeldahl method. The figures are given in Table 2.

It is evident that the extraction in the cold brought down first of all a large part of the inorganic constituents of the germ, among which iron and sodium were found, and it is interesting that the split product which was most toxic, the soluble part at 120 C., was the one containing the largest percentage of nitrogen.

An ultimate analysis was made of the soluble part obtained at 100 C., this being the only one of which there was a sufficient quantity for the purpose. The powder was dried to constant weight, and its constituents determined with the results given below. Carbon and hydrogen were determined by combustion, nitrogen by the Kjeldahl method, phosphorus in the ash by precipitation first with ammonium molybdate, then with magnesia mixture, sulphur by the alkali method[3] (fusion with potassium hydrate and nitrate, solution of the residue in acidified water, and precipitation as barium sulphate), and oxygen by difference.

TABLE 3.—Split Product at 100° C.

	C	H	N	S	P	O
With ash (5.28 per cent.)	45.73	5.95	10.34	1.13	0.386	36.46
Ash free	48.27	6.28	10.92	1.45	0.403	32.67

There was also an undetermined amount of iron.

The water solution of this split product gave good tests for the biuret, xanthoproteic and Millon's reactions. There was also a Molish's reaction, indicating a carbohydrate group, which was further supported by the fact that after boiling the substance with dilute acid, Fehling's solution was reduced. The split product was evidently proteid in nature, though a compound proteid. It could not have been a protamin, for the protamins are much richer in nitrogen, containing 30 per cent. or more. A comparison of its percentage composition calculated ash free with the percentage composition of ash free animal proteid as given by Hammarsten[4] is worthy of note, although a more extensive comparison with most of the known protein substances shows that its composition more closely resembles that of the group of glycoproteids, the mucin substances, especially that of a mucin from the mucus of sputum, and a mucoid from tendon, as given by Cohnheim.[5] The figures are given below. These glycoproteids, however, differ from the split product in that they contain no phosphorus. Only two phosphorized glycoproteids are known,[6] namely, ichthulin,[7] occurring in carp eggs, and helicoproteid,[8] obtained from the glands of the snail, and their percentage composition does not compare closely with that of the split product. Ichthulin has sometimes been classed with the nucleoalbumins. These phosphorized glycoproteids, like the split product, yield a reducing substance on boiling with acid.

TABLE 4.—Comparison Percentage Composition of Various Proteids with that of Split Product.

	C	H	N	S	P	O	Fe
Split product, (ash free)	48.27	6.28	10.92	1.45	0.403	32.67	+
Animal proteid, (ash free)	50.6-54.5	6.5-7.3	15.-17.6	0.3-2.2	0.42-0.85	21.5-23.5	
Mucin from mucus of sputum	48.26	6.91	10.7	+	—	33.1	—
Mucoid from tendon	48.3	6.44	11.75	0.81	—	32.7	—
Helicoproteid	46.99	6.78	6.08	0.62	0.47		+
Ichthulin	53.52	7.71	15.64	0.41	0.43		0.1

On the whole, the indications are that the split product obtained by the action of dilute mineral acid is of the nature of a phosphorized glycoproteid.

Blandine[9] reports the isolation of a nuclein and nucleoalbumin from cultures of the typhoid bacillus, while Brieger and Fränkel,[10] in their work on toxalbumins, found in cultures of the typhoid bacillus a proteid which was toxic for rabbits and which was thought to contain the typhoid toxin in an impure state.

THE NITROGEN OF THREE ACID EXTRACTS.

As has been indicated, there has been evidence of the presence of proteid bodies, so to study the distribution and amounts of the proteid decomposition products as obtained through the action of acid, it seemed expedient to make a more general study of the nitrogen content of the germ as extracted by acid. To obtain some idea as to the amounts of amido, monamido and diamido nitrogen in the decomposition of the germ by acid, represented by ammonia, the monamido acids and the hexon bases and to study their distribution when acids of different strengths were used, a comparative series was made, practically using the method of Hausmann.[11] By this method he determined the amido nitrogen determinable as ammonia, the nitrogen of the diamido bodies, as precipitated by phosphotungstic acid, and that of the monamido acids as found in the filtrate not precipitated by phosphotungstic acid. The method, while it has been severely criticized by Kutscher[12] and others, has still been shown[13] to give valuable *comparative* results, whereby general differences are plainly evident. The method of procedure was as follows:

Three 10-gram samples were extracted for five hours on the sand bath with reflex condensers, using 90 c.c. of 1 per cent., 5 per cent. and 33 1/3 per cent. sulphuric acid, respectively, for the three samples. The residues were each then boiled for an hour with 100 c.c. of water, and this added to the extract, the whole being then diluted to 200 c.c. The ammonia of each extract was determined in two samples of each by distilling with magnesia. Then the total nitrogen of all three extracts was determined by the Kjeldahl method. The extracts were next each made to contain 5 per cent. sulphuric acid, the required amount being added to the 1 per cent., and the 33 1/3 per cent. being diluted with the necessary amount of water. After this, each extract was precipitated with 25 per cent. phosphotungstic acid, and allowed to stand twenty-four hours, when the precipitates were filtered out, washed with diluted acidified phosphotungstic acid, dried, weighed and powdered, and the nitrogen determined by the Kjeldahl method. The nitrogen was also determined in the filtrates from these precipitates and in the dried residue remaining from the acid extraction. The results are given in Table 5. All the acid extracts gave the xanthoproteic and Millon reactions for proteid, and all, save the 33 1/3 per cent., the biuret test.

TABLE 5.—NITROGEN AS AMMONIA.

	1 %	5 %	33 1/3 %
Amount of extract	200 c.c.	200 c.c.	200 c.c
Wt. N as NH_3 in 200 c.c.	0.0112 gms.	0.0112 gms.	0.0112 gms.

TOTAL NITROGEN OF EXTRACTS (Including N as NH_3).

	1 %	5 %	33 1/3 %
Amount of extract	200 c.c.	200 c.c.	200 c.c
Wt. N in extract	0.4284 g.	0.7644 g.	1.0164 g.

PER CENT. TOTAL NITROGEN OF EXTRACT COMING OFF AS NH_3.

1 %	5 %	33 1/3 %
2.6143	1.4652	1.1019

The amount of amido nitrogen split off was the same in each case, which pointed to a definite cleavage regardless of the strength of the acid. The percentages varied, of course, since the total nitrogen of the extracts was different. The largest amount of total nitrogen was found in the 33 1/3 per cent. extract, and hence the smallest per cent. of amid nitrogen, while the smallest total nitrogen was in the 1 per cent. extract. The amid nitrogen varied from 1.1 per cent. to 2.6 per cent. Hausmann[11] found approximately 1.2 per cent. amid nitrogen in true proteids, which was in accordance with the results of other investigators.

TABLE 6.—CALCULATED FOR THE GERM SUBSTANCE (10 gm. sample used).

Total nitrogen.	Amid nitrogen.	Per cent. of total N of germ as amid nitrogen
11.55 %	0.112 %	0.97 %

The total nitrogen of the germ was determined by kjeldahling samples of the germ powder. The per cent. of amid nitrogen was found from the fact that 0.0112 grams nitrogen was obtained from each of the three extracts from 10-gram samples.

TABLE 7.—NITROGEN OF THE PHOSPHOTUNGSTIC PRECIPITATES.

	1 %	5 %	33 1/3 %
Wt. ppt.	7.8220	12.8602	16.9792
Wt. N in ppt.	0.2014	0.3429	0.2029
Per cent. N in ppt.	2.575 %	2.667 %	1.197 %

The largest amount of diamido nitrogen was found in the precipitate from the 5 per cent. extract. It is probable that the 33 1/3 per cent. acid was strong enough to further decompose the diamido compounds and so lessen their quantity. In working for hexon bases a 5 per cent. acid extract might be expected to produce the largest yield. The per cent. of nitrogen in the precipitate from the 1 per cent. and 5 per cent. extracts were notably close together, and it is of interest that the 2.66 per cent. nitrogen found in the precipitate from the 5 per cent. extract was quite close to the 2.68 per cent. nitrogen calculated by Gulewitsch[14] in the phosphotungstic precipitate of arginin, but the carbon and hydrogen found were about twice what he calculated. His figures were C, 3.44 per cent.; H, 0.74 per cent., while we found C 8.34 per cent. and H 1.68 per cent.

TABLE 8.—NITROGEN OF FILTRATES FROM PHOSPHOTUNGSTIC PPTS.

	1 %	5 %	33 1/3 %
Total amt. of filtrate	200 c.c.	260 c.c.	260 c.c.
Wt. N in whole filtrate	0.0315	0.07189	0.36218

The largest amount of monamido nitrogen was found in the filtrate from the 33 1/3 per cent. extract; the smallest in that from the 1 per cent.

TABLE 9.—NITROGEN OF RESIDUE LEFT FROM THE ACID.

	1 %	5 %	33 1/3 %
Wt. residue from 10 gms. germ substance	3.9630	1.7322	0.7308
Wt. N in residue	0.4633	0.1924	0.0457
Per cent. N in residue	11.6900	11.1064	6.2631

The per cent. of nitrogen in the residues from the 1 per cent. and 5 per cent. acids was not greatly changed from that of the original germ substance (11.55 per cent.), which would seem to indicate that the residue was still undecomposed.

CONCLUSIONS.

From this research it may be concluded that there is present in the cellular substance of the *Bacillus typhosus* one or more compound proteid bodies, one of which, at least, seems to be of the nature of a phosphorized glycoproteid. Further, that proteid bodies are split off by the use of dilute acid, cleavage taking place regardless of the strength of the acid, so long as it is quite dilute; and that the total amount of this cleavage product which can be split off by dilute acid composes about 10 per cent. of the weight of the dry germ substance. And, lastly, that the cleavage of amido nitrogen by acid is definite regardless of the strength of the acid; that the largest amount of diamido nitrogen is obtained by the use of 5 per cent. acid, as compared with that obtained by the use of 1 per cent. and 33 1/3 per cent., while the largest amount of monamido nitrogen is found in the 33 1/3 per cent. acid extract.

THE CHEMISTRY OF BACILLUS COLI COMMUNIS.*

MARY F. LEACH, PH.D.,
Holder of Ford Fellowship in Physiological Chemistry in the University of Michigan.
ANN ARBOR, MICH.

In a previous paper[1] I have given a résumé of the literature on the chemical composition of bacteria, and a report of some preliminary work on the colon bacillus. This work demonstrated that the dried germ substance after extraction with alcohol contains 8.6 per cent. of ash, one-third of which ash is phosphorus, while sodium and potassium are the most abundant metals. Extraction with dilute sulphuric acid and treatment of the residue with a weak solution of sodium hydrate sufficed to bring practically the whole of the germ substance into solution. In the acid extract indications were found of xanthin and hexon bases, carbohydrate, much phosphorus and a toxic substance insoluble in alcohol. From the alkaline extract a nuclein body containing 2.93 per cent. of phosphorus was obtained, and evidence of carbohydrate was found. In these preliminary experiments the amounts were too small to admit of the purification and identification of the products, but they served to show several lines of work that could be profitably pursued. Along two of these I can report progress, although neither is completed:

Pure colon cultures obtained from feces were grown on 2 per cent. agar in the large incubating tanks used in this laboratory. After from seven to fourteen days the growth was removed, freed from agar, extracted first with alcohol and then with ether, dried and pulverized. This material was heated on the waterbath for an hour, with forty times its weight of 1 per cent. sulphuric acid, and filtered. The extract was poured into from three to five volumes of alcohol. The precipitate formed was washed with alcohol until the washings were no longer acid, then dissolved in water and reprecipitated with alcohol. When this precipitate first comes down it is white, flocculent and voluminous, but it darkens on exposure to the air so long as it is moist. With care it can be obtained as a light-colored powder. This substance holds moisture tenaciously. After standing for six months in a bottle with a glass cap, samples absorbed water in the process of weighing in an open watch glass. Small samples (0.5 g.) on watch glasses in vacuo over sulphuric acid dried to a constant weight in ten days, or in a weighing bottle at 98 degrees C. in from seven to eight days. Larger amounts heated for a few days at 98 C. and then in an oven between 105 and 110 C. required still longer time, and occasionally, but not invariably, showed signs of decomposition before becoming constant.

* See footnote to previous article.

[1] Trans. Assn. of Amer. Phys., 1902.

This substance liquefies on burning, gives off volatile products with the odor characteristic of nitrogen compounds, and leaves a dark residue. Hammarsten[2] says of the nucleins that they yield an acid coke containing metaphosphoric acid, which is consumed with great difficulty. Probably the same occurs here, and in burning the organic matter out of the liquid mass, some of the mineral constituents are volatilized. For this reason determinations of ash are unsatisfactory. An average of several estimations gives 30.74 per cent. of incombustible and non-volatile matter. The amount of inorganic matter is probably even higher, and includes the metals present in the organism as integral parts of the cell or taken up from the alkaline culture medium and from the tank. All these would be seized with great avidity by the acid used in the extraction. The sulphates thus formed appear in the alcoholic precipitate. The ash is not wholly soluble in either nitric or hydrochloric acid. It contains sulphate, as shown by barium chlorid and by the silver coin test, and also phosphate, as shown by ammonium molybdate.

Determinations of phosphorus in the ash by the molybdate-magnesia method show that 5.3 per cent. of the substance is phosphorus. Sulphur was determined by fusion with potassium hydrate and potassium nitrate and precipitation as barium sulphate. This element was found to be present to the extent of 9.22 per cent. Nitrogen determinations by the Kjeldahl method give 6.49 per cent. Comparing these figures with the results obtained from the germ substance, we have the result shown in Table 1.

TABLE 1.

	Ash	N	P	S
Germ substance.........	8.61	10.65*	2.87	none in ash.
Cleavage product.........	30.74	6.49	5.3	9.22
Cleavage product, ash free		9.40	7.68	....

* Air-dried samples not at constant weight were used for this determination.

This acid cleavage product dissolves in water giving an opalescent solution and is acid to litmus. The solution becomes clear and transparent on the addition of a trace of alkali. It gives a very slight biuret test, possibly due to a trace of proteid carried down with the precipitate. There is too much sulphate present for a satisfactory Millon test. Nitric acid reacts vigorously and gives a sharp xanthoproteic test. It gives a good furfurol test with a-naphthol, but does not reduce Fehling's solution either before or after boiling with HCl. The toxicity of this substance was discussed in the paper already referred to.

HEXON BASES.

Since a chain of six carbon atoms seems to be the favorite combination for the carbohydrates found in nature, it is certainly interesting that Kossel and others have found the open chain of six or five carbons in so many forms of albumin. For in animal metabolism a large part of the proteid is changed into carbohydrate, and as Cohnheim[3] suggests, this change can be most readily accomplished by oxidizing preformed chains of six carbon atoms. In view of Kossel's[4] theory that the three hexon bases, histidin, arginin and lysin, are fundamental constituents of proteids, and thus a necessary part of the molecule, it seemed desirable to determine their presence or absence in the bacterial cell, especially as I have found no record of such an investigation. To be sure, if tuberculosamin[5] is like other protamins, it contains hexon bases, but in the article cited there is no mention of this point. In the isolation of the bases Kossel and Kutscher's[6] method was followed with some modifications. The germ substance was boiled with acid for several hours. The xanthin bases were removed by addition of silver nitrate to the acid solution.[7] Histidin was precipitated by silver nitrate and barium hydrate to slight alkalinity; arginin by silver nitrate and barium hydrate to excess; and lysin by phosphotungstic acid.

In the first series of experiments at every step in the process, indications pointed to the presence of all these bases, but in the end, sticky hygroscopic substances were obtained, and these would not crystallize. In two sets of experiments frequent determinations of the amount of nitrogen in the solution were made by the Kjeldahl method; 173 g. of air-dried germ substance was boiled with nine times its weight of 33 1/3 per cent. sulphuric acid. This was filtered, and the residue boiled with water until the washings gave only a slight precipitate with phosphotungstic acid. The extract contained 18.37 g. of nitrogen; 10.62 per cent. of the germ substance, or 96.53 per cent of the total nitrogen in the germ. The residue contained 0.659 g. of nitrogen. After precipitating the extract with phosphotungstic acid there was left in the solution 9.655 g. of nitrogen, which is 5.58 per cent. of the germ substance; 50.73 per cent. of the total nitrogen, or 52.56 per cent. of the nitrogen of the extract. The phosphotungstic precipitate then contains 8.715 g. of nitrogen; 5 per cent. of the germ substance, 45.8 per cent. of the total nitrogen, and 47.44 per cent. of the nitrogen of the extract.

Following the common assumption that phosphotungstic acid separates the monamido from diamido compounds, these results can be expressed in Table 2.

TABLE 2.—DISTRIBUTION OF NITROGEN IN EXTRACT WITH 33 1/3 PER CENT. ACID.

	Grams.	Per cent. of Germ Substance.	Per cent. of Total N in Germ Substance.	Per cent. of N in Extract.
Germ substance........	173.	......	.....	......
N in extract................	18.37	10.62	96.53	100.00
N in residue...............	0.659	0.34	.....	......
Monamido N...............	9.655	5.581	50.73	52.56
Diamido N.................	8.715	5.04	45.8	47.44

In another series of experiments the nitrogen was determined at every step; 100 g. of germ substance was extracted repeatedly with 5 per cent. sulphuric acid.

[7] Kutscher: Chemische Untersuchungen über die Selbstgährung der Hefe, Zeit. f. physiol. Chem., 1901, xxxii, 59.

TABLE 3.—DISTRIBUTION OF NITROGEN IN EXTRACT WITH 5 PER CENT SULPHURIC ACID.

	Per cent. of Germ.	Per cent. of Total N in Germ.	Per cent. of N in Extract.
Total N	10.65	.....	......
N in extract	9.58	89.99	100.00
Humin N	1.48	13.90	15.81
N removed by precipitation of:			
xanthin bases	0.464	4.36	4.84
histidin and arginin	1.726	16.21	18.01
N in solution for histidin	0.454	4.27	4.74
after precipitation with phosphotungstic acid	0.358	3.36	3.73
N in solution for arginin	0.657	6.17	6.86
after precipitation with phosphotungstic acid	0.223	2.09	2.33
N in solution for lysin	2.83	26.55	29.50
N in solution for monamido compounds	1.704	16.00	17.78

Comparing these two tables, the extract with 5 per cent. acid appears to contain a larger proportion of diamido compounds and a less proportion of monamido compounds, but the results were disappointing. The persistence of certain proteid reactions, the sticky, hygroscopic residue, that resisted all devices for crystallization, point toward the presence of albumose, peptons or similar bodies.[8] The various reagents also failed to give as sharp separations as they should were the hydrolysis complete; hence, the use of the weaker acid was discontinued, although it is possible that with longer boiling it would have sufficed. By repeated reprecipitation or after more vigorous hydrolysis crystalline compounds were obtained. In view of the discussion on the value of phosphotungstic acid in separating monamido and diamido compounds, as well as the difficulties which various investigators have encountered in obtaining crystalline products in searching for hexon bases, it is perhaps well to give these data.

The silver precipitate of the histidin fraction was decomposed, reprecipitated by mercuric sulphate,[9] decomposed again with hydrogen sulphid, treated with hydrochloric acid and concentrated. The silver precipitate from the arginin fraction was decomposed and treated with nitric acid. In both cases crystals were obtained which await purification and identification. The phosphotungstic precipitate of the lysin fraction was decomposed with barium hydrate, concentrated to a thin syrup and precipitated with alcoholic picric acid. Beautiful, slender needles were obtained corresponding in appearance and decomposing temperature to the data given for lysin picrate, and to lysin picrate from fibrin and gelatin. This picrate yields a chlorid corresponding in appearance and melting point to the chlorid of active lysin. This work will be reported in detail as soon as possible after its completion.

It is interesting to note the similarity between bacterial proteid and other proteids, as illustrated by this and other investigations. In my former paper it was suggested that the cell studied was made up largely of [illegible] With Aronson's[10] osazone from [illegible], the xanthin bases obtained by Nishimura[11] and others, and these crystalline products from the colon germ, have been obtained from bacteria, well-characterized decomposition products representing the three great complexes of this class of substances.

Anesthesia.—In many cases, more skill is required to give the anesthetic than to do the operation.—Stone, in *Colorado Medical Journal.*

INSUFFICIENTIA PYLORI.*

MARK I. KNAPP, M.D.,

NEW YORK CITY.

Too long has the unfortunate opinion prevailed that a chronic dyspeptic is doomed to lifelong misery, if not, indeed, to suicide, which too often is the tragic finale to his existence. The recognition of insufficientia pylori as one of the causes of chronic dyspepsia is of paramount importance, as it leads to almost miraculously quick improvement. This is my opinion, based on over 50 consecutive and successful cases.

One hour after Ewald's test breakfast (I shall use here test meal and test breakfast as synonyms) the healthy stomach should yield from 30 to 50 c.c. of chyme, the solid part of which should be well pulverized and the fluid part very *thin. The chyme should readily* filter. Not always, however, do we meet such conditions. There are pathologic variations on either side of the normal, both as to quality and quantity.

NORMAL GASTRIC ACTION.

Insufficientia pylori is *the condition in which nothing* or possibly but 1 or 2 c.c. of chyme are aspirated one hour after the test meal; this is because the pylorus either does not close at any time or does so insufficiently *for a shorter period than is normal.* I shall beg your indulgence if I begin with the cause of the physiologic, clonic closing of the pylorus on introducing anything into the gastric cavity.

The presence of matter in the stomach causes its muscular fibers to contract, the degree of such contraction being in direct relation to the degree of the irritant. Normally, the exciting cause is not so great as to throw at once the entire stomach into one convulsive contraction, but the contraction begins at the fundus and travels toward the pylorus. While one band of muscle fibers contracts, the next band begins to relax. These successive contractions we call peristalsis. Let me say here, in parenthesis, that respiration has a decided influence on peristalsis; inspiration aids the motility of the stomach. When the peristaltic waves finally reach the end of the stomach, the pylorus, this likewise contracts, just as does the stomach. But, although the cause and the mechanism are identically the same, the effect on the pylorus is different from that on the stomach in general. The same cause and the same degree of contraction which produces in the stomach cavity but a diminution of its diameter, causes in the pylorus its entire occlusion. This is very readily explained by the difference between the diameter of the stomach cavity and the narrow lumen of the pylorus. The pylorus, having a very small diameter, needs but little contraction to occlude its entire lumen. No difference of force. cause or mechanism is required to explain the physiologic, clonic closure of the pylorus during gastric digestion. What produces general gastric peristalsis also produces closure of the pylorus; the closing of the pylorus must not be regarded as anything else than ordinary peristaltic contraction.

THE ABNORMALITIES.

Starting from these normal physiologic premises, we can reason that what will cause greater general contraction of the stomach will so *much more* intensify the closure of the pylorus, but as the general stomach cavity has a considerable lumen to contract on, while the same aggravated contraction reaching the pylorus has nothing more to contract on than its own anatomic structures, it is evident that such anatomic structures will suffer the consequences of such repeated and spastic contractions. Our knowledge of inflammation, its causes and its manifestations, would at once make us anticipate inflammatory changes of the pylorus under the conditions just mentioned. But, beside this, which I might call an intrinsic cause, there is the additional element of the violent impact of the chyme which is thrown against a closed pylorus by the aggravated contractions of the muscle fibers of the stomach. Thus we see two forcible factors for the production of inflammation of the pyloric portion. This explains why autopsies show, in by far the largest majority of cases, only the pyloric portion to be the seat of lesion. In fact, I believe we should be justified in discarding the name of gastritis in the majority of instances and substitute the name of pyloritis instead.

---

* Read at Albany before the Medical Society of the State of New York, Jan. 26, 1904.

The muscularis of the stomach naturally has a muscular, hence a dynamic, function, and, in accordance with the work to be performed, varies its development. In the grain-eating birds, for instance, the muscular layer of the stomach is enormously developed, because the grains have first to be crushed before they can be acted on, chemically, by the digestive secretions. Likewise in man the stomach completes the grinding begun by the teeth. This is a fact which is attested by the very finely pulverized chyme so often aspirated from the stomach. But is this very finely pulverized chyme really the result of only dynamic, of only muscular, activity? Yes. This affirmative answer can be verified in both direct and indirect ways. I have many times experimented with artificial digestion, and although I did obtain all the chemical results, I never did get the solid parts finely pulverized until it was thoroughly stirred up with a clean glass rod. The clinical proof presented itself to me in a case of pyloric stenosis, in which I first ascertained that the stomach was empty before I gave the ordinary test meal. One hour after it I aspirated the entire ingested meal. and, notwithstanding that the general acidity was as low as 18 (even dimethyl scarcely reacted) the ingested roll was recovered in a very finely pulverized form. On the other hand, there are abundant clinical instances in which the chyme is coarse, although there are sufficient acid values.

These facts I consider beyond doubt to be entirely conclusive that finely pulverized chyme is the result of mechanical crushing. Crushing implies that the object to be crushed must come between two opposing forces—the driving and the resisting force. In the stomach the contracting muscle fibers represent the driving and the closed pylorus the resisting force. The stronger these two forces act on one another or the longer the grinding continues, the finer pulverized will be the crushed product. Again, the finer the pulverization the longer or the stronger was the muscular contraction, and the longer did the pylorus offer resistance. We therefore must admit that to obtain a very finely pulverized chyme the ingesta must be subjected to the action of the forces mentioned, sufficiently long, which means that the ingesta must remain in the stomach long enough to be acted on, dynamically, by the muscular contraction of the stomach. In the same manner the aspiration of a chyme which presents the very fine pulverization, termed by me the "floury layer," attests the existence of at least normal if not hypermotility of the stomach, and this irrespective of the quantity aspirated. Nay, as it needs a prolonged contraction of muscle fibers also of the pylorus. as it needs a longer closing of the pylorus to produce the "floury layer," it is evident that the closed pylorus also prevents the passing of chyme into the intestine; hence a larger quantity will be aspirated. The larger the quantity and the finer the pulverization the longer did the pylorus offer resistance, the longer was the pylorus closed. Since, however, a protracted closure of the pylorus could not exist without active peristalsis (as explained above), and since a prolonged closure of the pylorus obstructs the escape of chyme, and hence leaves more chyme to be aspirated, it follows that the aspiration of a large quantity in which the "floury layer" is present signifies that in such a stomach peristalsis was very active.

This is a view diametrically the reverse of what is at present recognized. We are taught that a stomach which yields a large quantity of chyme after the test breakfast is atonic. We have been made to believe that the presence of a large quantity of chyme after the test meal incriminates the integrity of the muscular power of the stomach; it is being assumed that because the ingesta did not pass the pylorus in sufficient quantities in the given time it is ample proof that the stomach wall, for some reason or other, has not attempted to expel its contents. With the same propriety we might accuse the prisoner of not attempting to come out of his cell. Supposing the cell is locked and bolted and all efforts of its inmate to get out of the cell are frustrated because of the door being locked? The tonus of muscular fibers is judged by its respective power. But when we aspirate a "floury layer," such facts prove muscular activity. To accuse a stomach of atony, which yields after a test breakfast a large quantity of chyme of which the solid part is very finely pulverized, is a crime. Such stomachs are not only not atonic, but the very contrary; they are hypertonic. The large quantities aspirated in such cases is due to the stenotic condition of the pylorus. This stenosis is, most usually, due to a pathologico-chemical condition. and which I described as "stenosis of the pylorus from irritation." It is peculiar and possibly significant that both Boas and myself have independently worked on the same theory at the same time. Boas in his article on Magensteifung[1] also refutes the present assumption that the aspiration of a large quantity of chyme after the test breakfast signifies atony. He also acknowledges a stenosis of the pylorus as the cause of the large aspirated quantity.

I again wish to impress that quantity does not impugn the integrity of the muscular coat of the stomach one way or the other; quantity is dependent on the respective condition of the pylorus. A prolonged contraction of the pylorus offers prolonged resistance to the escape of chyme from the stomach, hence a larger quantity will be aspirated. A pylorus, the contraction of which is lessened or entirely abolished, offers little or no resistance at all to the exit of the chyme, hence a much larger quantity of the ingesta will pass the portals of the intestines unmolested, unchecked, and hence little or no chyme at all will be obtained on aspiration. There is no increase of motility in this condition, as there is no impairment of the muscular activity when a large quantity is aspirated. The absence of chyme one hour after the test breakfast can not be ascribed to hypermotility, as hypermotility means hyperactivity, which is synonymous with hypercontraction, and hypercontraction, as explained above, must produce more spastic contraction of the pylorus. Hypermotility of the stomach, therefore, effects larger quantities to be retained in the stomach. The presence of a large quantity of chyme after the test meal means stenosis, the absence of chyme denotes insufficientia pylori. But very little peristalsis is necessary to bring ingesta past an open pylorus; mere gravity will do it. Furthermore, the absence of pyloric resistance has a decided negative effect on the grinding up of the ingesta. Because of the absence of one of the two forces, mentioned above as necessary for the grinding, because of the absence of pyloric resistance by reason of its non-closure or insufficient closure, the ingesta can not be acted on dynamically. and therefore it is. that whatever little is aspirated in the first stages of insufficiency is coarse.

---

[1] Deutsche med. Wochenschrift, March 6, 1902.

Insufficientia pylori presents itself in several stages. It begins with a simple weakness, if I may use this expression, when possibly yet 1 or 2 c.c. of coarse chyme is aspirated and ends with its complete inability to contract. In this last stage the ingested food rushes immediately past the pylorus; the patient practically has no stomach. Between these extremes there are many gradations. We may not find any chyme at the end of one hour, but there may be some, three-quarters or half, or one-quarter of an hour after ingestion. and it is our duty to absolutely ascertain the exact condition.

ETIOLOGY.

Insufficientia pylori is the natural and logical successor to stenosis of the pylorus (I am not speaking here of the stenosis of an organic nature). It is but a question of time when the pylorus, too long insulted by spastic contractions and by the violent impact of food together with other chemical causes, will succumb to such maltreatment with the inevitable inflammation as the result. And once this is chronically established, we can easily foresee the consequences; that finally, in the very last stage, anadenia gastrica should result, need not surprise. Very seldom is insufficientia pylori the sequel of a retrograded neoplasm as described by Ebstein.[2] Directly, insufficientia pylori is caused by a chronic pyloritis. As remote causes are organacidia gastrica,[3] chronic alcoholism, loss of teeth and the gulping down of food.

SYMPTOMS.

Per se insufficientia pylori gives no symptoms, and it may exist for a long time without the patient being aware of it. What the patients complain of is due to faulty intestinal digestion; and usually the patients do not seek medical advice before the intestinal functions are interfered with. The most predominant and the most constant symptoms are due to gas formation in the bowels. This is variously interpreted by the patient as boiling, running around, shaking, heaviness. tension, sensation of bearing down, sensation of insufficient defecation. A woman about the climacterium thought she positively felt "quickening," notwithstanding her menstruation having been regular up to the time of her consultation. The appetite is variable, and may be good or absent, but there are definite causes for each. When the gases formed in the intestines are not irritant, then the distension causes anorexia. When the gases are volatile, fatty acids, then the attendant contractions of the upper part of the intestine due to the presence of such volatile acids, give the sensation of hunger. In the prevailing of the latter contingency, besides the very good appetite, will be diarrhea, cramps and rectal tenesmus, and, if the volatile fatty acids make their way through the upper passage, there will be burning along the route and thirst. Constipation is not infrequent, and I am now inclined to believe is due to distension of the bowel by non-irritating gases. Often constipation alternates with diarrhea, the diarrhea being subsequent to and caused by the constipation. The stagnating feces finally undergo putrefactive changes with the evolution of irritating gases, which then irritate the bowel, thus bringing on peristalsis. Headaches may or may not be present, but as yet I have not been able to ascertain the exact cause of each. The dictum that constipation and headaches invariably go together I can not corroborate, although it holds good in most instances. Flashes of heat and cold are very common, especially in the evening after the somewhat heartier meal, which the insulted intestines struggle to digest. It can be safely assumed that one who abuses his stomach will also abuse his bowels, if not warned in time. But often patients are not aware of serious gastric trouble or of any digestive interference. Occasional "spells" they take very lightly, often as a matter of course. The following case illustrates this:

> A young man, aged 28, a traveling salesman, had been coughing for some three years, during which time he consulted several general practitioners without being helped. Finally, being alarmed about his cough, he went to a prominent specialist on diseases of the chest, who, after the third visit, came to the conclusion that most likely the cough was caused by some disorder in digestion. The patient then came to me, rather surprised at the specialist's finding, as he could not remember any serious attacks of indigestion. That patient's stomach had already advanced to the condition of insufficientia pylori. His cough stopped permanently after the sixth day (he came for treatment every day).

Vomiting may or may not be present. Beside those there may also be other symptoms.

DIAGNOSIS.

Insufficientia pylori can not be diagnosed without a test-meal, nay, several test-meal examinations, one to follow the other one day after the other. Absence of chyme one hour after the test breakfast, or at most 1 or 2 c.c. of coarse particles, is the diagnostic criterion. The diagnosis should be corroborated by another test meal the very following day. In a tentative way the diagnosis may be assumed in cases of chronic alcoholism or in patients with few or no teeth. Neither sex nor age gives any clue. The diagnosis of insufficientia pylori having been made. it becomes our duty to ascertain exactly the patient's condition. The question, and a very important one, is, how soon is the stomach empty? Does the stomach functionate at any time, or has the patient practically no stomach? These questions are answered by aspirating the stomach at various times after the test breakfast is given. If the stomach prove to have no chyme one hour after the test meal, we next day aspirate three-quarters of an hour after the ingestion, or thirty, or even fifteen minutes after the eating. On this exact knowledge is based the successful treatment. When the case is properl[illegible] patient, he will usually corroborate [illegible]. If we can manage it all real medications should be stopped for a few days before our examinations. Of the physical examination only gastric inflation may be of some avail. In the last stages of insufficiency the stomach can not be inflated by any means. But one must be careful not to mistake a dilated stomach for insufficientia pylori, should he choose for inflation CO_2 developed in the stomach. The usual doses for inflating a stomach are half a teaspoonful each of bicarbonate of soda and of tartaric acid, each to be taken separately and in immediate succession with about two ounces of water. If these do not inflate we need not yet conclude on insufficiency.

---

[3] Medical Record, Sept. 6, 1902.

PROGNOSIS.

If not attended by too severe complications insufficientia pylori has an excellent prognosis, no matter how old is the patient or how long the disease had existed. I have seen cases, in my own practice and in consultation, in which the conditions prompted the gravest diagnoses and where improvement had been despaired of, respond almost miraculously to the proper treatment. A marked turn for the better is positively seen in a very few days, often even within a day or two after treatment has been begun. Patients who have suffered for years from chronic dyspepsia get well, gain flesh and change their melancholy into buoyancy and optimism in a very short time. Thus I had among my patients a colleague about 50 years of age, who until recently taught diseases of the stomach, and who had to give up his position because of ill health, greet me on the twelfth day after the test-meal examinations with a hearty hand shake, a broad and cheerfully smiling "How do you do," and a slap on my shoulders. This greeting needed little interpretation. My esteemed colleague had not a trace of chyme even half an hour after his test breakfast. The usual average for the treatment has proved to be about three months. Often the patients are inclined to overbear, exhilarated by the rapid success, and are tempted to do a little experimenting themselves. Against this the physician must guard. A return of the pylorus to the normal can only be expected in the young. I have seen this several times.

TREATMENT.

As everywhere else, the etiologic moment must be kept in mind. Alcoholism and gulping down of food will naturally be interdicted. It is much better to go without food than to swallow it down unmasticated. If circumstances do not allow the patient sufficient time for his meal, then let him have such food as needs no mastication. Mastication must at all times be complete. Loss of teeth must be supplanted by artificial ones. Especially to the poor must we explain the necessity of thorough mastication. But, as they can not always get a set of good artificial teeth, we must advise them to have the mastication done artificially. All cereals and vegetables should be well boiled and eaten in the form of puree. As to meat, my advice is to prepare it any way they like, and after it is done, to cut it up into very small pieces, which is best done by a meat-grinding machine, which is very cheap.

The dietetic treatment is of chief importance. The object is not to introduce any acid food nor food which develops gases. Let us also remember that sweets very quickly form acids in the digestive canal, consequently also these will be omitted from the dietary. Coffee, tea, spirits, fermented liquors, CO_2 containing waters, too much milk, cabbages, peas, beans, radishes, turnips, spices, salads, whole grain bread and other cereals with their husks (the easily fermenting cellulose) on, fruits, especially grapes, peaches, plums and prunes should be forbidden. Excluding these, the patient has a free choice of food but not of drink. Clean, filtered water and milk are about all the patient can have. Of mechanical treatment only lavage is to be mentioned if mucus is present. I have as yet not tried electricity.

The medicinal treatment must be directed to help the intestine, but at the same time not to interfere with any gastric digestion, which may still be present. It is for this reason that several test-meal examinations are necessary. We must know whether the stomach does have some digestion, and if so, we surely must not interfere with it by giving the alkalies too soon. Bicarbonate of soda, magnesia and the rhubarb and soda mixture are usually sufficient and to be given after meals, the time to be determined by the test-meal examination. So, for instance, if there is no chyme even fifteen minutes after ingestion of the test meal, then the alkalies should be given immediately after meals. If there is some gastric digestion yet a half hour after the test breakfast, then the alkalies will be given between half an hour and one hour after meals. If there is some gastric digestion still present, the alkalies should be given somewhat later when meat is eaten. Pancreatin and papain are very valuable, but we must be sure to get the fresh products; stale products are very apt to be decomposed and cause pain, colics and diarrheas. Strychnin is the drug never to be left out, but it must not be given in small doses. I never begin with less than one-twenty-fifth of a grain. Especially in the chronic diarrheas has the strychnin a magical effect. Cases in which there were daily ten to twenty watery discharges and which have lasted for years, in one case over eight years, have yielded entirely and permanently to strychnin in from three to four weeks. But in these cases the strychnin must be given in rapidly advancing doses. I repeatedly gave one-seventh of a grain three times daily.

For constipation sodium sulphate and liberal quantities of water are of most benefit. The sodium sulphate should be begun with one-half teaspoonful doses in a glassful of hot water half hour before meals; this dose should be diminished gradually according to requirements. When the drinking of large quantities of water is desired, it is best not to tell this plainly to the patient, as he will usually disobey. Any sort of drugs—and by far the most impressive are bitter drugs—can be given in drop doses every two hours in a tumblerfull of water.[4]

THERAPEUTICS OF INSANITY.[*]

ORPHEUS EVERTS, M.D.
CINCINNATI.

Since the insane of Christian countries were rescued by the hand of science from the despotic barbarism of superstition, they have been treated rationally, if not successfully, as persons suffering bodily infirmities. The therapeutics of such treatment may be classified, for convenience, as medical, hygienic and disciplinary. Medical therapeutics consists of the administration of materials supposed to be curative of diseased conditions. That medicines administered to the insane are not always, but are, indeed, seldom curative, is a "huge criticism" of present states of knowledge respecting both disease and medicine.

Were man a rational as well as a reasoning being, it might not be exacting to require of physicians prescribing medicine for the insane to have some knowledge of the more intimate relation of function and manifestation to structure, in conditions of both health and disease, as well as a clear perception of the relation of drug-energy to physiologic activities before prescribing. But, considering the present state of knowledge—or ignorance, rather—of such ultimate biochemical facts as are still concealed in the arcana of organization common to the profession, physicians should not be criticised censoriously for prescribing for the insane as they do for others, empirically.

---

[4] I refer the reader to my previous articles on insufficientia pylori in the Philadelphia Medical Journal, May 24, 1902, and in the New York Medical Journal, Oct. 4, 1902.

[*] A posthumous paper written for the Section on Nervous and Mental Diseases, New Orleans Session, 1903. It is the last production of its gifted author, whose death occurred June 19, 1903.

The general trend of empiricism in medicine is—as it ever has been—to antagonize physiologic by medicinal energy. Thus, in treatment of acute mania, manifested by increased mental and muscular activity indicative of excessive elimination of physiologic energy, medicines recognized as sedative are almost invariably prescribed. In the treatment of melancholia, manifested by diminished activity of organic processes, and corresponding indisposition to motion, mental or muscular, stimulants or tonics are as uniformly resorted to. Whether curative or not, in either case statistics should be able to determine.

Purgative medicines are given to the insane, as to other persons, without reference to mental symptoms. Insane persons supposed to be suffering a specific dyscrasia, now recognized as a cause of insanity, become the recipients—necessarily—of what is called "specific treatment."

When I assumed the superintendency of a large state hospital for the insane, nearly forty years ago, the principal drugs in vogue for the treatment of the insane were, leading the list of sedatives, that ancient and respectable drug, opium, and its derivatives, followed by conium, hashesh, hyoscyamus, belladonna, etc., to which potassium bromid, chloral hydrate, sulfonal, trional and other chemicals of great energy were subsequently added.

Of stimulants and tonics in use then were, leading the list, that ancient companion in respectability and use of opium—alcohol—variously embodied, closely followed by quinin, iron, arsenic, zinc and numerous bitter vegetable extracts, since supplemented with phosphorus and strychnia. Favorite purgative drugs were calomel, colocynth, rhubarb, Epsom and Rochelle salts, and various other cathartic or laxative materials.

Thus equipped, therapeutically, the insane were persistently medicated—as they have been ever since—along lines before suggested, of physiologic and medicinal antagonism; modified but little by the suggestions of science, nor entitled to consideration as illustrative of medical progress in any sense. Therapeutically, so far as medication is concerned, our treatment of the insane is not a day in advance of that of Hippocrates; the real and great benefit that the insane have derived from science having been physiologic, hygienic and ethical, rather than medicinal. In some respects, indeed, as an individual observer, I believe the insane are not as well treated, medicinally certainly, if history can be trusted, nor so successfully as they were fifty or a hundred years ago. It is true they are not now bled till they can not wag their tongues nor wave their arms because of loss of energy thus abstracted; nor intentionally mercurialized with the expectation of "attracting morbid activities from the brain to the mouth," as they were in the days of the immortal Dr. Rush. But they have been, and are being, narcotized with increasing frequency and profundity, to a degree of sedation more perilous—however deceptive in appearance—than was accomplished by the great American Sangrado's lancet.

Sound blood we know is not only essential to all healing processes, but is indispensable to continued functioning of all living mechanisms. It is, indeed, Nature's first, last and only trustworthy weapon of offense and defense in her maintenance of human existence. It can not, therefore, be either spilled or poisoned with impunity. Loss of blood, within certain limitations, may be more readily recovered from under favorable circumstances than repeated and profound intoxication is likely to be. In the one case new blood is rapidly supplied to repair loss; in the other, old contaminated blood has to be purified by slow elimination, often leaving permanent injury. The facility of administration of some of the more potent poisons, by the use of our modern, serpent-fanged hypodermic syringe, from which the most violent or obstinately unwilling patient can not escape, to be followed so soon by such charmingly happifying consequences, silence and repose, has greatly increased temptation to administer them, without serious or philosophic consideration. What relief, indeed, to the overwrought consciousness of friends, nurses and other inmates of a home or hospital ward a physician can give by a magic drop of virus instantly injected beneath a patient's skin, soothing almost instantly the maniac's rage, silencing his voice, and quieting his hyperenergized muscles into a semblance of "Nature's sweet restorer, sleep!" The practice is not curative, however, nor more than exceptionably justifiable in properly constructed and equipped hospitals for the insane. In private practice, the rights of others than the insane may justify such sedation, although not contributive to recovery. A wise engineer, when he finds his machine endangered by an excess of eliminated force, opens wide a valve and lets the superfluous energy escape, with no matter what shrieking and agitation. Nature—by which we mean the small fragment of the universe and such facts and phenomena as have become familiar to us—may not appear to be, at all times, supremely intelligent and rational; but, as a rule, it is safer to trust her than to antagonize her. We appeal with confidence to our own reasoning capabilities, as against Nature's conduct of affairs, forgetting that reason as an intellectual capability is as facile and potent in confirming error as it is in the establishment of truth.

Of stimulating or tonic medicines, as now administered in the treatment of the insane, but little need be said. So long as given in such quantities as do not offend the stomach or impair digestion, they are practically harmless, if not really helpful.

Purgative or eliminating medicines are generally useful in the treatment of the insane, as they are in the treatment of other classes of persons suffering derangement of physiologic functions. Preachers have often been censured for commendation of quack medicines. They do sometimes give good medical advice, as, for example, that given to a sick sister by a good Methodist parson, who, after praying at her bedside, left with her the injunction: "Put your trust in God and keep your bowels open!"

Hygienic therapeutics are in accordance with the suggestions of common sense or human experience, and modern science as well. The primary necessities of all living beings are: air, food, water—and, if human—light, warmth and exercise.

That the self-helpless insane should be environed with reference to all these requirements is a logical affirmation. That they are not, and can not be, so circumstanced in the ordinary homes of the people in this or any other country, is likewise true. Properly located and constructed public and private hospitals for the insane come as near to supplying all demands indicated as is practicable. Of these prime necessities the value of air and water, as to both quantity and quality, as related to health, is more likely to be underestimated than is that of less important items. Perfect ventilation and abundance of wholesome water commend a hospital more highly than any other characteristics. Without the actual presence of water, organization can neither be effected nor its functional capabilities maintained. It is safe to affirm also that much disease now attributed to auto-infection is sequential to widely prevalent neglect on the part of civilized peoples to make an intelligent use of water; internally more especially than externally.

Keeping one's skin clean is a decent and goodly thing to do. Our skins are so constructed, however, that even "dirt diseases" seldom effect entrance to vital organs through them. Mucous membrane—skin deprived of armor, its "coat-of-mail"—is at all times vulnerable. Keep it clean! Pure water is Nature's solvent and detergent, and should be employed as such with great confidence. In prescribing water for the insane, however, no influence of suggestion need be anticipated, such as attends the recommendation of celebrated mineral water to be drank at or from notable springs, on the part of fashionably neurotic invalids of a different class. The insane are, as a rule, too stupid or too conceited to be thus influenced. The high-sounding names of various baths, as advertised for effect, Roman, Turkish, Russian, electric and others, do not attract attention or inspire confidence or hope when appealing to the insane. And the fact is, that pure water, wherever found, is sufficiently medicinal for all physiologic purposes as a drink; and the modern rain bath of fully equipped hospitals is equal to all therapeutic necessities in the treatment of the insane. The uniform application of heat or cold to the whole surface of the body, at discretion, constitutes the therapeutic virtue of a bath, as warmth and moisture constitute a poultice, without regard to name or materials implicated.

Professional massage, Swedish-movement appliances and other things reminiscent of medical eccentricities of once important pretension as comprehensive systems of cure, may still appeal with some force to the credulous and hopeful, but not to the crazy.

Electricity has never been generally employed in the treatment of the insane, so far as I know. I am informed that electrical appliances are being introduced as part of the equipment of modern hospitals for the insane, but whether for use or display I do not know. I have had many psychopathic patients committed to my care who had been previously subjected to electrical treatment—ignorantly, for the most part, it is to be presumed—none of whom seemed to have been benefited, and some of whom seemed to have been seriously injured thereby. This fact, however, does not discredit the therapeutic value of electricity in the hands of qualified administrators; nor should it discourage anyone from endeavoring to learn more and more respecting its applicability as a force in the cure of disease. It is a phase, however, of universal energy so weird and so intimately associated with human notions respecting supernatural beings, that when exploited as an agent capable of performing miracles in curing disease, appeals so powerfully to the imaginative and superstitious. I have habitually regarded its common use as—if anything more than an "appeal"—doubtfully dangerous. As an appeal, the insane are not affected thereby.

Occupation, manual labor, so much insisted on as hygienically beneficial to the insane, is commendable as both useful and economical. It is applicable, however, almost exclusively, to the conditions of chronic insanity, conditions no longer necessarily pathologic, but because of which their sufferers are permanently impaired and incapable of independent social life.

The same may be said of amusements. Neither the maniacal nor the morbidly melancholy can be amused successfully. The psychic activities constituting the mental ego of the one are too eccentric, of the other too centric, to admit of diversion or entertainment. Nor have I ever known a person suffering from acute mania or melancholia benefited by travel, on either land or water.

Diet, as pertaining to hygienic rather than to medicinal therapeutics, justifies mention in this connection of a long list of fake-foods and pretentious "tissue-builders," liberally advertised by samples and literature, that, in my estimation, are more profitable to the producers than to the consumers. "Build up the tissues" is a high-sounding injunction without a suspicion of commercialism in its tone. One might think, on hearing it announced as from an oracle of science, in connection with recommendations of these new-fangled products, that all a physician need to do in order to induce or compel Nature—however crippled or exhausted her forces—to resume constructive labor and "build up the tissues" is to administer any one of a number of "predigested," "peptonized," "malted" or otherwise hocus-pocus foods; or some chemically composed pabulum so nearly protoplasmic as to build tissues itself without Nature's co-operation or consent. If one trusts the "true-seeming lie," as the red-cross knight did the "false-fair dream" that the magician Archimago compelled Morpheus to forge and send for his deception, as related in Spencer's "Fairie Queen," he will eventually awake from the delusion a wiser if not a better physician.

Disciplinary therapeutics, in the treatment of the insane, is second only in importance to hygienic helps. Loss of self-control and loss of moral sensibility are characteristics of insanity. To meet necessities incidental to such conditions, more or less restraint is essential to the welfare of the insane, and that of others entitled to protection from them. The question of to-day is, as it ever should have been, not one of non-restraint, but of what method of restraining should be adopted for the welfare of all concerned. To say the insane do not require restraint is to say they are not insane, or that they are capable of exercising the rights or privileges of free citizens, an inference whose rationale the very existence of numberless hospitals for their custody as well as cure emphatically denies.

There are three methods of restraining the insane. One is by mechanical appliances; another by the administration of paralyzing medicine; and a third by moral influences. Of these methods, moral influences are sufficient for by far the greater number. In hospital practice the sense of restraint that falls like a shadow from hospital facades and towers on persons committed to hospital care, still capable of some appreciation—ethical and esthetical—is both efficient and salutary. There are exceptional persons, however, who, because of pathologic conditions, are incapable of recognizing moral influences of any kind. Noisy, destructive, belligerent, homicidal and restless, what shall be done with them? The choice is between mechanical and medicinal means. Restraint by the hands of attendants is as distinctly mechanical as is that by a camisole or a protection bed, and much more exasperating to the patient. Medicinal restraint, I believe, at the present time has displaced to a great extent mechanical appliances in public and private hospitals in this country and Europe. Modern psychiatry has been persuaded or driven by a tidal wave of pseudo-philanthropy, started by the popular acclamation attending the reform inaugurated by Dr. Pinel in France and Mr. Tuke in England late in the eighteenth century, to abandon mechanical appliances for restraining the insane—nominally if not really—under all circumstances. This "great reform," however, like all other sentimental movements looking to the accomplishment of social, political, moral or religious ideals, in the promotion of which important factors of the problem determining the limitations of practicability are generally left out of consideration, overleaped itself and defeated its own ends. That there was demand and occasion for modification of old practices, including needless mechanical restraint, there can be no question. That prohibition of mechanical means, instead of regulation within legitimate limitations, was an error, is to me equally apparent. The inevitable substitution of chemical narcosis, or physical force attended occasionally, however ordinarily concealed, by scandal, can not be said in the full face of facts to have justified the boast or the claim of beneficence to the insane, as a consequence. The outside world approves, unquestionably, of the transition. The outside world judges from superficial appearances, not from carefully observed and analyzed facts; the fact, for instance, that this transition from mechanical to other forms of restraint—especially the narcotic form—has been attended by marked diminution of the ratio of recoveries to the number of insane persons admitted to the hospitals of this country and Great Britain.

There may be other factors in the problem, but none so conspicuous or so suggestive. If, as is now believed, much insanity is attributable to auto-intoxication, what should be rationally expected from repeated and profound intoxication of persons already impaired, mentally, by chemicals capable of obliterating consciousness by paralyzing its mechanism?

It was not my purpose, however, to reopen this ancient burr; nor do I wish now to go on record in this, my last contribution to the literature of psychiatry, as an "old fogy," opposed to whatever is new or progressive. "Ancientism" has never been a feature of my religion, nor is it now. Looking before and after, it has ever been my habit to endeavor to see things stereoscopically as far as practicable, recognizing the fact that the wisest of mankind are not infallible, nor the best free from error.

Revulsion Treatment of Vomiting in Pregnancy.—Dumas applies revulsion to the breasts to divert to this point the tempest in the uterus. He believes that the close connection between the breasts and the genitalia is sufficient to explain the prompt benefit derived. He describes his technic in a communication to his local paper, summarized in the *Journal de Méd. de Paris* of March 6, 1904. He prefers cupping for the purpose, using a semispherical cup that fits airtight over the breast, with a rubber bulb to aspirate the air. The cup must be large enough to avoid all contact with the breast except at the base. He applies it morning and night and leaves it in place on each breast for twenty-five to thirty minutes. He suggests that this revulsion to the breasts might be found useful also in chlorosis or disturbances accompanying puberty.

THE ULTIMATE RESULTS OF THE BLOODLESS REPLACEMENTS OF CONGENITALLY DISLOCATED HIPS.*

JOHN RIDLON, M.D.
CHICAGO.

In selecting the subject of this paper I have been actuated by divers motives, but chiefly by the hope that a straightforward presentation of the facts, insofar as I have been able to obtain them, may correct certain delusions and false impressions that have crept into the minds of medical men and others, mainly through uninformed writers of sensational newspaper articles.

For the past five years no subject in orthopedic surgery has been of greater interest to me than this one—the bloodless replacement of congenitally dislocated hips. For the past three years no operation has been more generally discussed by the profession and the laity. No subject has been more persistently misrepresented by the lay press and, I regret to say, by the editorial writers of the medical press, and more thoroughly misunderstood than the results of this operation. Enough hips have now been operated on and enough time has now elapsed to give us a fairly accurate knowledge of the facts. These facts are what we wish to consider.

When the results from any operation are found to be quite different from the assertions of its advocates and the expectations of the profession it is likely to be unjustly condemned, and a humane means of relieving misery and suffering is likely to be lost to the world. Professor Lorenz, in [illegible] that the death of a patient be kept out [illegible], once said to me: "They have raised me up far beyond my deserts; if they learn of this they will cast me down equally far below my deserts." So with this operation. It has been raised up, mainly by the newspapers, far beyond its deserts. Some day, I fear, it will be cast down far below its deserts, unless the facts be made known and the failures freely admitted by those who practice the operation and believe in its utility.

That my paper may not be misunderstood—that I may not be misunderstood—let me say at once that I practice this operation in every suitable case; that I believe it is the best operation for all operable cases, and the only operation to be seriously considered in all bilateral congenital dislocations at the hip. The fact that the number of perfect anatomic replacements is few—far below what has been claimed and hoped for—should no more condemn this method than the fact that no cases of true scoliosis are perfectly straightened should condemn the treatment of scoliosis. We did not condemn excision of the breast for cancer when the ultimate mortality was 90 per cent. The operations, in selected cases, were generally successful, but the patients almost invariably died sooner or later from recurrence of the disease. No more should we condemn the operation of bloodless replacement if it should chance to appear that the perfectly stable anatomic replacements do not amount to more than 10 per cent. to 20 per cent. of the cases operated on. It is just simply unfortunate that Lorenz has claimed, or that we have understood him to claim, 80 per cent. "good results," and more than 50 per cent. "perfect anatomic replacements." It is greatly to be regretted that the people have been led to expect perfect results, as the rule, for they are awaking to bitter disappointment, and unjustly condemn earnest and skillful operators, if the operators chance to be honest men who admit the facts as to the results they obtain.

---

* Read before the New York Academy of Medicine, March 3, 1904. A report of this meeting will be given next week

The results which I have found and set down in this paper will, I trust, be an encouragement to those operators who have doubted their own skill, and, I hope, may prove of use to some surgeons in convincing their patients that the results they have obtained are at least reasonably good.

In a paper dealing with the ultimate results of the bloodless reduction of congenital dislocation at the hip, I do not feel called on to discuss the development of this operation. While Ochsner credits all that is valuable in the operation to Lorenz, Davis would ascribe the credit to Paci of Pisa. To quote from Davis' paper—a paper that contains the most historic value and the fairest estimate of the situation of any that has appeared—a description of Paci's operation may be permitted. It is as follows:

> Flex the thigh well on the abdomen and press down on the knee to bring the head beneath the acetabulum; slightly abduct the femur; rotate outwards while increasing the abduction and bring the limb slowly into extension, stopping short of the point at which relaxation occurs. In attempting this method Lorenz, not being satisfied with his results, resorted (contrary to Paci's teachings) to extreme force. In 1895, the year following the congress at Rome, he advocated powerful screw extension, internal rotation, and fixation in abduction. Later in the same year he advocated flexion at a right angle; forced abduction, supplemented at times by powerful manual extension (he abandoned instrumental extension) and fixation in a markedly abducted position in plaster, and allowed the patients to walk about instead of confining them to bed for four months, as did Paci. This he called his "belastungs," or functional weight bearing method, and Royal Whitman states that the utilizing of the weight of the body to form a new socket is the essential and vital distinction from the forcible correction of Paci, with which it is often confounded. It is but just to Max Schede to state that he had been using for 15 years the weight of the body for this very purpose. Lorenz claims to be the originator of a new method of reposition, as well as of retention. He modified Paci's procedures, whether advantageously or not remains to be seen. His most marked departure was the use of great force. Finding he did not obtain immediately by Paci's manipulations the result he desired he proceeded to force its accomplishment. When the adductors prevented abduction he deliberately tore them by overstretching; when the head would not come down he put on screw extension or manual pulling by two or three assistants; when the head would not come forward he put the trochanter on Koenig's block to increase the effectiveness of the abduction and extension.
>
> Outside of the use of excessive violence, extension, increasing the abduction and tearing of the muscles, the method remains one of circumduction like Paci's. Of these four modifications, the excessive violence has already and is still giving such deplorable results that it is certain to be modified or abandoned. Lorenz himself has given up his screw extension. Extension in many cases is unnecessary, and need never be violent. Its place is not under chloroform narcosis, but when the patient is in bed by means of weights. I fail to see the advantage of tearing over tenotomy. The formation of hematomas, from the middle of the thigh to the umbilicus, sloughs and abscesses which have accompanied the practice do not commend it to me.
>
> In using Koenig's block beneath the trochanter it is a simple substitution for the hard roll of Pravaz and the edge of the table as used by Paci for the same purpose. In many cases the use of the hand alone suffices. Paci himself apparently used such forcible abduction and extension as to fracture the thigh in one case, and this shows that he abducted and extended as forcibly as was justifiable. For these reasons I can not see anything peculiar to the Lorenz method of reposition except violence, and if only a moderate and justifiable amount of force is used the bloodless reposition is that of Paci, and should be so called. The papers of Paci at Rome in 1894 were followed by Lorenz's book in 1895, and the method of forcible reposition was taken up and practiced more or less all over the world.

The cases I have to report have been divided into four groups: 1, Those observed by me in Chicago before my first operation of bloodless replacement; 2, those observed by me from the time of my first operation, July, 1897, to the advent of Lorenz, October, 1902; 3, those examined or operated on by Lorenz that I have notes on, or that I have been able to obtain reliable information about; 4, those operated on by me and all others examined by me since Oct. 12, 1902. These four periods may, perhaps, be characterized as the period of indifference, the period of interest, the period of delirium, and "the morning after," when things look so differently.

CASES IN FIRST PERIOD.

The first group comprises the cases from the first seen by me in Chicago on February 28, 1894, to my first bloodless replacement in July, 1897. There were 10 patients; 12 dislocated hips. All were girls. The ages were from 15 months to 11 years; 5 were right hips, 7 were left; the shortening was from one-half inch to 2½ inches. I have been able to trace only two of these cases and learn their present condition. Case 3 was a girl 5 years old, with left dorsal dislocation and three-fourths of an inch shortening when first examined by me Feb. 15, 1895. She afterward went to an advertising orthopedic institution, and for three years was treated by a traction hip splint on which she was allowed to walk. Now, Jan. 29, 1904, four years after the traction brace was discarded, she can, in standing, fully compensate for two inches actual shortening; she has free abduction and hyperextension, and walks with not a bad limp.

The other, Case 10, was a girl 7 years old, with dorsal dislocation of the left hip. She was referred to me by an eminent neurologist from an eastern city as a case of infantile paralysis. She had been treated for two years by electricity, and had been examined in consultation by an eminent orthopedic surgeon of the same city. The parents rejected my diagnosis, and even refused for two years to have an *x*-ray picture made to settle the matter. Then when the diagnosis was finally settled by a skiagram they refused operation until Professor Lorenz came. At that time the child was 13 years old, a large, strong girl. There was real shortening of about 2½ inches, and practical shortening from flexion and adduction of about 5 inches. Professor Lorenz, after examination, said replacement was not possible, nor was transposition, but advised tenotomy of the flexors and adductors and putting the limb in an improved position and retention for a long period in a leather splint, while massage and active and passive exercises were given to insure the maintenance of the new position. On advice of surgeons in Germany this operation was rejected.

The cases in detail are as follows:

GROUP 1.

No.	Sex.	Age.	Hip.	Shortening.	Examined.
1.	F.	2 yrs.	L.	¼ in.	Feb. 28, 1894.
2.	F.	18 mos.	R.		June 20, 1894.
3.	F.	5 yrs.	L.	½ in.	Feb. 15, 1895.
4.	F.	6 yrs.	L.	1½ in.	May 27, 1895.
5.	F.	11 yrs.	L.	2 in.	July 1, 1895.
6.	F.	8 yrs.	B.		April 29, 1896.
7.	F.	10 yrs.	B.	2½ in.	Sept. 2, 1896.
8.	F.	4 yrs.	R.	1 in.	Nov. 23, 1896.
9.	F.	2 yrs.	R.	¾ in.	April 27, 1894
10.	F.	7 yrs.	L.	1⅛ in.	

OPINIONS OF VARIOUS OPERATORS.

The second period runs from my first bloodless replacement in July, 1897, to the first operation in this country by Prof. Adolph Lorenz of Vienna, on Oct. 12, 1902, and comprises 40 patients with 51 dislocated hips. During this time, in fact, at about the middle of this period, in November, 1900, I became sufficiently interested in the subject, the reduction of congenital dislocations at the hip, to write to many of the eminent orthopedic surgeons of this country, asking for their experience and opinions; and later I visited New York and Boston. Some of the replies are interesting reading.

Dr. Harry M. Sherman, San Francisco, wrote on Dec. 11, 1900:

> I have had only one of the bloodless plan that "stayed put." I believe there were about a dozen that were "put." With that case I am satisfied. . . . I do no more bloodless operations.

Dr. A. M. Phelps, New York, wrote on Nov. 19, 1900, that he had operated on several cases, but he did not say whether or not it was by the bloodless method. However, when I arrived in New York he had no cases to show me. They were all in the country or had been lost sight of.

Dr. E. H. Bradford, Boston, wrote on Nov. 25, 1900:

> All my cases of congenital hip reduced bloodlessly [he had reported on 44 hips in 34 patients[1]] have relapsed, except one about which I am doubtful. It is now two years since the operation, and I have an *x*-ray that is being developed. It seems to me that the hip has slipped since the previous examination three months ago.

I had an opportunity to examine the *x*-ray negative a few days later, and the replacement appeared to me to be a perfect one. Dr. Bradford had just returned from the International Medical Congress at Paris, and in the letter from which the foregoing is quoted, he further says:

> At the Paris congress an animated discussion on the bloodless and the operative measures was conducted by Lorenz and Hoffa. Each had cases which they operated on before the congress. The bloodless method, as carried on by Lorenz, has certain successful cases, but according to his own statement, as well as those of other surgeons, there is a percentage of relapse. According to Hoffa it is a very large percentage.

Drs. Shaffer, Gibney, Sayre and Hibbs of New York had had no cases of bloodless replacement in November, 1900, and Dr. Townsend of New York had only two, recently operated on.

Dr. H. Augustus Wilson, Philadelphia, had no successful cases, and knew of none in Philadelphia, on Nov. 17, 1900.

At the meeting of the American Orthopedic Association in New York, May 31 to June 2, 1899, Dr. Royal Whitman reported 32 operations on 22 hips in 21 patients. Three were cured; 5 were still under treatment; 1 was a failure; 1 could not be traced; 1 discontinued treatment; 8 were "transposed"; and 2 had had the open operation performed. It is not stated whether these two cases on which the open operation was performed were transpositions, relapses or failures by the bloodless method. It should be noted that only one of these 21 patients had both hips dislocated, and this case was still under treatment at the time of the report. It should also be remembered that it is more difficult to obtain perfect results in bilateral than in unilateral cases. Dr. Whitman mentions incidentally two cases operated on by Dr. Gibney, but in November, 1900, Dr. Gibney stated to me verbally that he had had no successful cases by the bloodless method.

In November, 1900, Dr. Whitman was able to give me the names of three other cured cases; two were unilateral and one bilateral. I looked up the bilateral case and found, in a child operated on when about 18 months old, a perfect anatomic replacement on one side and an anterior transposition, or what Lorenz calls "a good result," on the other side. Whitman's first operation was in July, 1896. He had operated on 22 hips by June, 1899, with three perfect replacements. From that time to November, 1900, I do not know how many he had operated on, but he had added three more cases to his list of perfect results. This you will realize, as I go on with my report, is a very creditable showing.

EXPLANATION OF TERMS USED.

Before considering the cases of this group and figuring the results, it may be well to consider the meaning of the terms used to characterize the results. By a failure, I mean that the operator has failed to apparently replace the femoral head in the acetabulum; and that he has also failed to effect anterior transposition. By "apparent replacement" I mean the condition which is usually demonstrated as a perfect replacement by the operator; where the sensation, and often the sound of the femoral head passing over the rim and into the acetabulum is present, together with shortening of the hamstring muscles showing that the head has descended from its original site and is resting more or less securely at a lower point. Lorenz regarded this symptom of shortening of the hamstrings as diagnostic of replacement, but Wilson of Philadelphia has demonstrated, postmortem, that this symptom may be present when the femoral head simply rests on the contracted opening of the cotyloid ring, and is in no sense in the acetabulum. This ought to have been obvious to all of us, but was not, before Wilson made his demonstration, for we have all observed, after the replacement has apparently been made and the thigh is in right-angled abduction and flexion, that, if we bring the limb downward toward its fellow, reducing the abduction and flexion, the femoral head sooner or later will slip from its resting place and pass up to its original site. If it slipped from its resting place easily we have said that the acetabulum was shallow; that it would be difficult to hold the replacement; that a perfect anatomic replacement might not be the result, and that we might only succeed in getting a good result. And by "a good result" we mean an anterior transposition. If, on the other hand, we found it possible to reduce the abduction to within 10 to 20 degrees of the normal, we have said that the acetabulum appeared to be a good one, and that the result would most surely be a perfect anatomic replacement. If the femoral head never really enters the acetabulum at the time of the operation, and at best only rests more or less deeply in the opening of the narrowed cotyloid ring, the phenomenon of slipping out more or less easily, or with more or less difficulty, but always slipping out when the limb is sufficiently adducted, or rather when the extreme abduction has been sufficiently reduced, is obvious. All the skiagrams I have seen taken immediately after the replacement have shown the femoral head some distance away from the bottom of the acetabulum, and it appears to me very doubtful if a perfect anatomic replacement is ever accomplished at the time of the operation. I trust, then, that you will permit me the use of the term "apparent replacement."

Of the cases apparently replaced at the time of the operation, a certain number ultimately result in perfect anatomic replacement. This has been questioned, but it is a proved fact—proved by Paci at the International

---

[1] Boston Med. and Surg. Jour., Oct. 25, 1900.

Medical Congress in Rome in 1894, where he presented the pathologic specimen of a case operated on by Notta, and proven also by the case reported by Edward Ochsner.[2] A considerable number of cases ultimately turn out "good results," that is to say, anterior transpositions, the femoral head lying to the front of the acetabulum, sometimes very near and sometimes far from the socket. If the head lies near the socket, and if it remains secure in its new position all of the characteristic deformity of congenital dislocation is effaced, namely, the shortening, the insecure step, the lordosis, the flexion and the adduction; it is a good functional result; only full inward rotation and full flexion are lacking. But if the anterior transposition is extreme, and unfortunately in some cases where it is not extreme, the femoral head gradually passes upward until it may be said to have relapsed into a supracotyloid dislocation, with shortening, outward rotation and insecurity. And, finally, some of the cases of anterior transposition suffer complete relapse by the femoral head passing upward and backward into its former position on the dorsum of the ilium.

By a supracotyloid displacement I mean a result where the limb is short, the greater trochanter displaced upward, and the femoral head can be felt above the acetabulum, anteriorly when the limb is rotated outward and posteriorly when the limb is rotated inward.

By an "improved position" we mean that the limb has been abducted, and thereby apparently lengthened, and the femoral head perhaps advanced somewhat, and the deformity due to the flexion, adduction and false shortening has been corrected, more or less completely, and that patient stands and walks in an improved position.

By a "perfect replacement" is meant a case where the femoral head, on palpation, can be felt no more distinctly in front, at the back, or above the acetabulum than in the normal hip; where there is no shortening, or not more than one-fourth of an inch; where the skiagram shows the femoral head as deeply within the acetabulum as normal, and where a final observation has been made at least six months after the removal of the splint.

Having explained the meaning of the terms used in discussing the results, it may be proper to speak briefly of the accidents that may befall one in making this operation. They are: Paralysis from overstretching; fracture of the neck of the femur; fracture of the shaft of the femur; fracture of the ramus of the pubes; fracture of the ischium; tearing of the perineum; rupture of the femoral artery; gangrene from cutting off the circulation through stretching the femoral vessels. There may be others, but these are sufficient for the surgeon who has experienced one or more of them.

SUMMARY OF CASES IN SECOND GROUP.

In the second group there were 40 patients, with 51 dislocated hips, 20 right hips and 31 left; 36 were girls and 4 were boys. Their ages were from 18 months to 13 years. The shortening was from one-half inch to 4½ inches.

Of these 51 dislocated hips, 24 were operated on, 12 rejected and 15 refused operation. Of the 24 operated on, there were 5 failures, 5 relapses, 1 supracotyloid displacement, 2 anterior transpositions, 2 perfect replacements and 9 apparent replacements. It is very likely that a large proportion of these 9 apparent replacements would be found to be either anterior transpositions or supracotyloid displacements could they be traced and radiographed.

Of the 5 relapses and 5 failures, 1 was subjected to Hoffa's cutting operation, and of the remaining 9, Lorenz operated on 5, with what result you shall see later. All the cases were dorsal dislocations except one, which was upward and forward.

In detail the cases are as follows:

GROUP 2.

Case 11.—Female, aged 10 years; left hip; shortening 2 inches. Operated on July 1897. Last examined Aug. 29, 1898. Apparently perfect result. This was my first operation and was made with considerable timidity. I was satisfied with getting the impulse of the head slipping into the acetabulum, and did not sufficiently stretch the adductor muscles. The case relapsed and was replaced in December, 1897, and again in February, 1898. On removal of the splint, Aug. 29, 1898, the replacement was apparently perfect. I am unable to trace the case and do not know the ultimate result.

Case 12.—Female, age 4 years; right hip; shortening 1 inch. Operated on Sept. 28, 1897. The plaster splint was worn nine months. A year later, June 14, 1899, the hip was apparently in place; there was a ⅛-inch shortening, and the patient walked without a limp. Three years later Dr. T. A. Davis presented the case to Professor Lorenz, and he operated. Some eight months later Dr. Davis removed the splint put on by Lorenz, and the femoral head at once slipped from its resting place in or near the acetabulum. Dr. Davis replaced the head and put on another plaster splint. The present condition is unknown; the parents refuse to permit an examination or a skiagram. The child walks with a limp and probably has a supracotyloid dislocation.

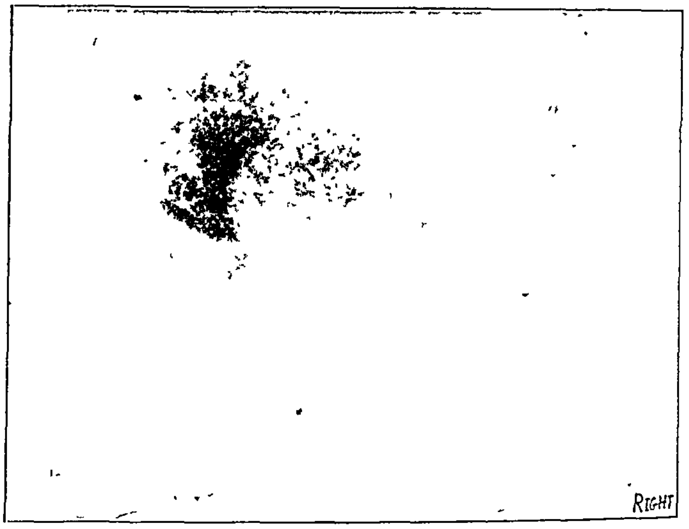

Fig. 1.—Case 18. Operated on by Ridlon. Relapse after four months Same as Case 91. Operated on by Lorenz. Skiagram after relapse and a year before Lorenz operated. See Figure 2.

Case 13.—Female, age 3 years; left hip; shortening 1¼ inches. Refused treatment.

Case 14.—Female, age 8 years; left hip; shortening 1½ inches. Operated on Feb. 9, 1898. Hip apparently in place when removed to Cook County Hospital, June 3, 1898, for diphtheria. Can not be traced.

Case 15.—Female, age 6 years; left hip; shortening 1 inch. refused operation.

Case 16.—Female; age 3 years; left hip; shortening ¾ of an inch. Operated on March 21, 1898. At the end of 13 months, when she passed from my care, the head was apparently in place; there was ⅛ inch shortening, and she walked with scarcely a limp. During the following winter she was treated by an osteopath for three months. I was permitted to examine the child 19 months after she passed from my care. There was a ⅝ inch shortening and the head could be felt above the acetabulum. The parents, trusting to the assurances of the osteopath that the hip was in place, refused to have a skiagram made and refused to believe that relapse had occurred. Two years later Professor Lorenz operated. The replacement was effected with ease for a seven-year-old child, as easily as most primary replacements in children of four. The acetabulum appeared to be good; and a perfect replacement was prognosticated as the ultimate result. When the plaster splint was removed some eight months later Professor Lorenz told the child's father that the head was in anterior transposition. This case illustrates the difficulty of prognosticating the final result at the time of operation.

---

[2] Annals of Surgery, August, 1902.

Case 17.—Female, 2 years; left hip; shortening ¾ of an inch. Operated on Oct. 20, 1899. Apparently perfect thirteen months later. Can not be traced.

Case 18.—Female, 20 months; righ hip; shortening ¾ of an inch. Operated on Oct. 18, 1898. Relapse. (Fig. 1.) The child's mother has bilateral congenital dislocation of the hips. Oct. 17, 1902, Lorenz operated. (Fig. 2.) When the plaster was removed in May, 1903, the femoral head was found in anterior transposition. Since then it has become supracotyloid, and there is ½ an inch shortening.

Case 19.—Female; age 3 years; both hips; shortening 1 inch. Refused operation.

Case 20.—Male, age 6 years; left hip; shortening 1¾ inches. Operated on March 31, 1899. Failure Later I assisted Dr. L. L. McArthur in making Hoffa's cutting operation. The wound became infected, and the ultimate result was a stiff hip, with adduction deformity and practical shortening as great as the actual shortening had been before the operation

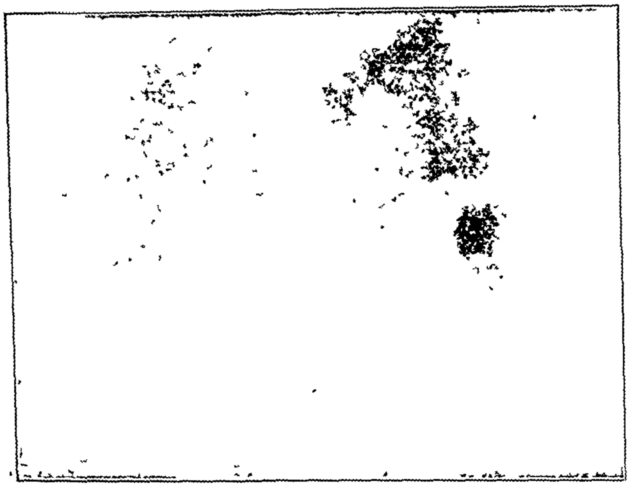

Fig 2—Cases 18 and 91 Operated on by Lorenz Apparent replacement Found anterior on removal of splint

Case 21.—Female, age 12 years; both hips; 2½ inches. Rejected

Case 22.—Female, age 8 years; left hip; shortening 1¾ inches. Two operations by me; both failures. Dr. Christian Fenger had previously made several unsuccessful attempts Nov. 26, 1902, when the child was 11 years old, after 4 weeks preliminary weight and pulley traction in bed, Lorenz operated, but failed to replace and failed to transpose. The adductors were freely torn, and the limb put up in the abducted position. At the end of 8 months the mother removed the plaster splint, and since then the child has had no treatment.

Jan 18, 1904, there was 2¼ inches actual shortening, but only about ½ an inch practical shortening, so free is the abduction and so good the compensation by dropping the hip She walks on the ball of her foot without high shoe, and with very little limp.

Case 23.—Female, age 5 years; both hips; shortening 1¼ inches. Refused operation.

Case 24—Female; age 12 years; both hips; shortening 2¼ inches' Rejected.

Case 25—Female, age 6 years; left hip; shortening ½ an inch. Operated on Oct. 2, 1899. Reported perfect six months later by Dr. F. C. Test. Can not be traced.

Case 26.—Female, age 6 years; right hip; shortening ¾ of an inch. Operated on Oct. 11, 1899. On July 12, 1900, the femoral head was in anterior transposition.

Case 27.—Female, age 6 years; left hip; shortening 1¼ inches. Operated on Nov. 22, 1899. Failure.

Case 28.—Female, age 9 years; left hip; shortening 1½ inches. Operated on Dec. 13, 1899. May 25, 1900, apparently perfect. Jan. 22, 1904, there was found to be supracotyloid dislocation, with 1½ inches shortening. She walks on the ball of her foot, without a high shoe, with little limp, and can fully compensate when standing. Figure 3 shows an acetabulum too shallow to be of any use.

Case 29.—Female, age 7 years; left hip; shortening 1⅞ inches. Rejected.

Case 30.—Female, age 4 years; left hip; shortening 1 inch. Refused operation. No treatment since.

Case 31.—Male, age 3 years; both hips; shortening 1 inch. Operated on April 30, 1900. Right apparently perfect; left relapsed. Has not been seen recently; present condition unknown.

Case 32.—Female, age 3 years; right hip; shortening ¾ of an inch. Refused operation.

Case 33—Female, age 4 years; both hips; shortening 1¼ inches. Operated on Dec. 30, 1900. Right hip relapsed during the second month while in the plaster splint, and treatment of this hip was abandoned until a good result should be had on the left side. The plaster splint was removed from the left hip at the end of seven months, and replacement was apparently perfect. During the following three months the femoral head came forward far enough to be felt in the groin. Dr. Fenger was of the opinion that it was an anterior transposition, and such I have reported it. The child walked on this limb for eighteen months without any shortening resulting, and when Professor Lorenz operated on the right hip on Oct. 12, 1902, he examined the left hip and said: "That hip is good enough for any one." He did not say whether he considered it a perfect replacement or an anterior transposition.

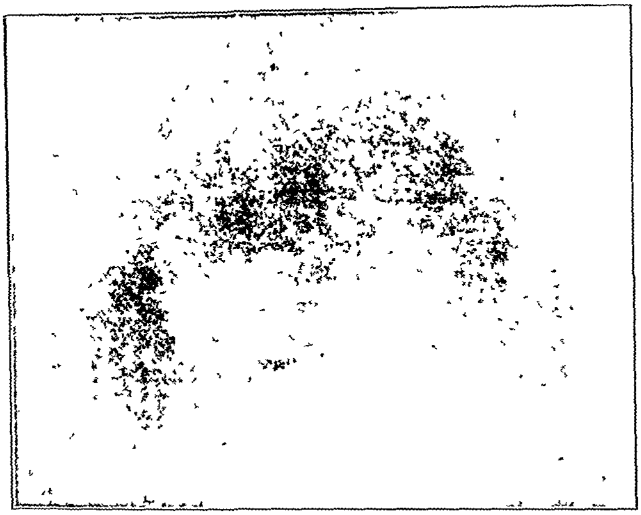

Fig. 3—Case 28 Operated on by Ridlon Hip apparently in for six months after operation, on removal of plaster splint Skiagram Jan 22, 1904, 8½ years after operation, shows a 'saucer-shaped' acetabulum and a supracotyloid displacement.

When Professor Lorenz removed the splint from the hip he had operated on (the right) the limb was found to be shorter than the one I had operated on, but the head appeared to be in place. After about three weeks of daily massage and manipulation by Professor Lorenz an anesthetic was again given and the limb again stretched and manipulated, and again put in a plaster splint. The result has been stated by Professor Lorenz to be an anterior transposition, or "apposition," less good than the result in Case 16.

Case 34.—Female, age 4 years; left hip; shortening 1 inch. Refused operation.

Case 35.—Female, age 12 years; both hips; 3¼ inches. Rejected.

Case 36.—Female, age 4 years; left hip; shortening ⅞ of an inch. Upward and forward dislocation (Fig. 4). Operated on March 29, 1901. Relapsed. Again operated on Nov. 22, 1901. Apparently perfect replacement.

Case 37.—Male, age 2 years; left hip; shortening ¾ of an inch. Operated on May 17, 1901. Aug. 16, 1901, apparently perfect. Can not be traced.

Case 38.—Female; age 8 years; right hip; shortening 2 inches. Rejected.

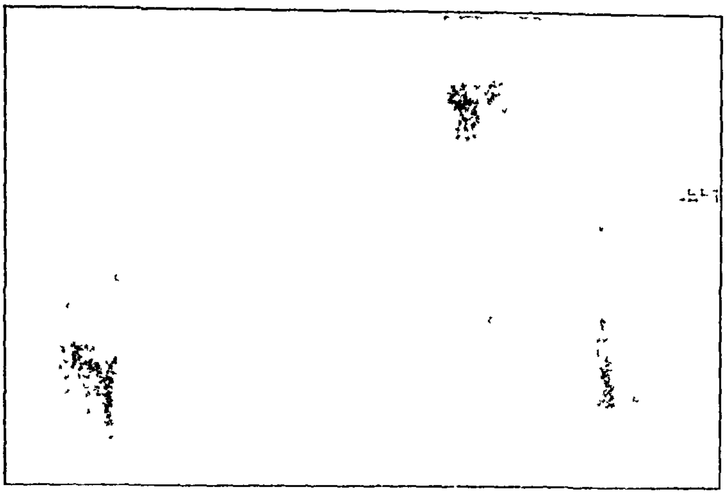

Fig 4—Case 36 Dislocation upward and forward Before operation Two operations were made Perfect replacement when last examined 3 months after removal of splint.

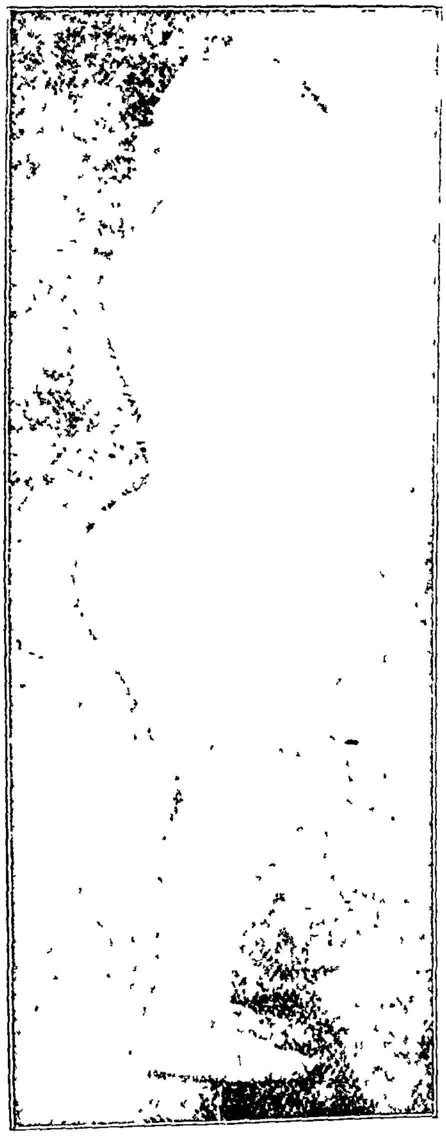

Fig. 5—Case 39. A rejected case

Case 39.—Female, age 12 years; both hips; shortening 4½ inches. Rejected. Afterward rejected by Lorenz. Figure 5 illustrates the kind of case that is impossible to treat.

Case 40.—Female, age 18 months; right hip; shortening 1 inch Refused operation.

Case 41.—Female, age 6 years; both hips; shortening 1¾ inches. Refused operation. Has had no treatment since.

Case 42.—Female, age 13 years; left hip; shortening 3 inches. Rejected.

Case 43.—Female, age 2 years; left hip; shortening ½ an inch. Operated on June 30, 1902. In July, 1903, the result was perfect, and child walked without a limp.

Case 44.—Female, age 2 years; both hips; shortening 1 inch. Operated on Sept. 21, 1902, and put up with knees considerably posterior to the transverse mid-plane of the body. The child was very fat and two previous replacements had relapsed. On removal of the splint at the end of eight months the femoral heads were distinctly anterior. The knees were brought forward until the heads appeared to rest in the cotyloid rings and plaster splint was again put on for two months. Since then there has been such massage and exercises as the mother could give. When last seen the replacement appeared to be perfect, but I have no skingram and I think it more than likely that supracotyloid displacement will result.

Case 45.—Male, age 7 years; right hip; shortening 1 inch Refused operation.

Case 46.—Female, age 2 years; right hip; shortening ¾ of an inch. Refused operation.

Case 47.—Female, age 4 years; left hip; shortening 1¼ inches. Operated on Sept. 20, 1902. Perfect replacement

Case 48.—Female, age 7 years; both hips; shortening 1½ inches. Two operations; both failures. Afterward operated on by Lorenz.

Case 49.—Female, age 12 years; left hip; shortening 2½ inches. Rejected.

Case 50.—Female, age 3 years; right hip; shortening 1 inch. Refused treatment. Afterward operated on by Lorenz.

(*To be continued.*)

THE COMPOSITION OF SOME SO-CALLED SYNTHETICS AND "ETHICAL" NOSTRUMS.*

WILLIAM J. ROBINSON, M.D.
NEW YORK CITY.

One fine morning. some weeks ago, a young lady, an actress by profession, came to consult me about an obstinate headache. "I have used everything you can think of," she said. "I have used antikamnia, Kohler's headache powders, ———'s migraine tablets, orangeine, Hegeman's headache wafers and a lot of other things. At first they used to relieve me, but now they don't do me any good." The self-drugging young woman enumerated five different articles which she had used; different articles in name, but identically the same so far as composition is concerned. Everyone of those articles consists of acetanilid, sodium bicarbonate and a little caffein. Finding a malarial history, I prescribed quinin and ergotin, and her headaches promptly vanished.

About two weeks later a young practitioner approached me at the close of a medical meeting with the following words: "Doctor, I wish you would recommend me something good for dysmenorrhea. I have an obstinate case for which I tried everything you can think of." "What did you give her?" I asked. "Oh, I gave her *antikamnia*, phenalgin, salfene, phenobromate and all the various combinations recommended for dysmenorrhea. They have a slight effect, but only temporary." Here we have a physician, a man who paid out a thousand dollars in tuition fees in a medical college. who does exactly the same thing as the ignorant young woman; that is, he prescribes for his patients things of the composition of which he knows absolutely nothing. All the nostrums he enumerated contain acetanilid as their chief and principal ingredient, and he did not know it! A professional man, and he did not care to make the least investigation into the nature of the drugs he prescribed! Had he done so, he would have spared himself the trouble of prescribing the same drug over and over again under a different name, and his patient's sufferings might have been alleviated by more rational treatment. How can we blame the laity for self-drugging and for swallowing mixtures of which they know nothing, when regular physicians are doing the same thing right along. The above is by way of preface, and now to the subject of the paper.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs S. Solis Cohen, George F. Butler and N S Davis, Jr.

Something must be done to stop the avalanche of nostrums which threaten to overwhelm and bury the general practitioner, which put barnacles on the wheels of therapeutic progress, and which throw confusion into the minds of those who have not made pharmacognosy and materia medica a special study, and even into the minds of those who have. No one who has not given the subject especial attention can imagine what impudent mendacity, what incredibly absurd claims, what impossible statements are indulged in by those nostrum manufacturers who have made the physician their special prey. And not only this; downright dishonesty is practiced in taking an old well-known compound, christening it with a new name and offering it to the physicians as a new discovery, as a new synthetic with wonderful properties, as one possessing all the virtues of the old compound with all the drawbacks eliminated. If we take into consideration the difference in the education of the medical profession and of the laity, and compare the statements of the "ethical nostrum" manufacturer with those of the regular quack patent-medicine man, we will find that the ones are not in the least less extravagant than the others. It would be impossible to enumerate and to discuss all the fakes and humbugs that are foisted on the attention of the medical profession. I must, therefore, be satisfied with giving a few illustrative examples. The examples are not by any means unique. They are typical of numerous other cases.

Some three years ago a preparation appeared on the market heralded as a wonderful new antipyretic alkaloid, non-depressant, a specific in typhoid fever, etc. Numerous cases were reported by a certain class of practitioners testifying to its value in various conditions. An impossible formula was appended, and it was launched as one of the great discoveries of the twentieth century. One would hardly believe it, but it is a fact which can be demonstrated before the eyes of everyone, that this wonderful new discovery is nothing but impure acetphenetidin. I was so astonished when I made the discovery that I thought I would apply to some authority for confirmation of my findings. I wrote to Prof. Virgil Coblentz of the New York College of Pharmacy, and he answered me that I was perfectly correct; that it was nothing more nor less than impure acet-para-phenetidin, that is, phenacetin. He added: "Possibly traces of salicylic acid have been added to the product from time to time, for obvious reasons, yet this does not alter the fact that we have before us in this preparation an impure phenacetin. This is a positive assertion, based on the results of a number of examinations." The same company puts up a [illegible] is asserted to be bismuth oxyiodid [illegible] According to analysis, it is merely bismuth gallate, with a small quantity of free gallic acid; no iodin could be traced in the examined specimen. Another specialty, greatly boosted as a wonderful remedy in uric-acid poisoning, is claimed to be acetyl methylene di-salicylic acid. According to analysis, it is simply an impure methylene salicylic acid, which can be easily produced from salicylic acid by means of formaldehyd and muriatic acid. The presence of an acetyl group could not be established in the examined sample, either by heating with water or with alkalies, or with concentrated sulphuric acid. On heating a substance with concentrated sulphuric acid and alcohol, if acetyl is present, the odor of acetic ether is noticed, while with this preparation, there is not a trace of acetic ether observed.

Hemaboloids was also introduced with a loud beating of drums. Beautifully executed charts were given, showing the various kinds of blood corpuscles, the great increase in the number of erythrocytes, etc. The prepation was asserted to be "a palatable fluid food, partially digested and made aseptic and more assimilable by treatment with nuclein, rich in iron and phosphorus-producing elements," and it is said to consist of "vegetable nucleoalbumin (Nature's supply source of iron and phosphorus for the human system), reinforced by bone marrow extract and beef peptones." What are the facts? A careful analysis has demonstrated the total absence of nuclein or bone marrow; and, further, that the preparation is nothing more nor less than an alkaline 1 per cent. solution of iron peptonate in a vehicle of alcohol, glycerin and water, flavored with spirit of orange. The amount of alcohol it contains is large, namely, 16 per cent., stronger than any ordinary wine. According to Professor Harrington of Harvard, the maximum *daily* dose recommended yields about *one-fourth of an ounce* of nutriment, and the alcoholic equivalent of about an ounce and a half of whisky.

While I am on this subject of hemaboloids, I might touch briefly on prepared liquid foods in general. Most of them are a snare and a delusion, and I have no doubt that we frequently starve our patients on those "concentrated, predigested foods." As an example, I will take the most popular, because the oldest of the liquid foods, namely, liquid peptonoids. This is said to contain "the albuminoid principles of beef and milk and wheat," and asserted to produce immediate and pronounced effects in cases of feeble digestion and wasting diseases; dose, for an adult, one or two teaspoonfuls, three to six times daily; children in proportion.

The maximum amount recommended for an adult will yield less than an ounce of nutriment, and the alcoholic equivalent of three and one-half ounces of whisky per day. Analysis shows 23.03 per cent. by volume of alcohol, 14.91 per cent. of total solids, and 0.17 per cent. of mineral matter.

The above examples illustrate the extravagant and false assertions made by certain manufacturers regarding the composition of their products.

There is another class of products about the composition of which no assertions are made. Nothing is stated about the chemical composition, because the products being common mixtures requiring no brains, skill or knowledge, any false assertions would render the proprietors ridiculous. Therefore they say nothing about the composition of their products; they simply tell you: prescribe our goods; they produce wonderful results; you need not know what they consist of, we will look out for that. All you want to do is to order in original packages and use according to directions. And, sad to say, there are numerous physicians who do just as they are told. To give the composition of a few of these preparations might not be without interest:

Antikamnia: This nostrum has been shown hundreds of times to consist of acetanilid, sodium bicarbonate and caffein. Its cost is about 3 cents per ounce; it is sold at $1 per ounce; The poor druggist and the public pay, and the manufacturers make millions.

Salfene: Composition, acetanilid and sodium bicarbonate.
Phenolid: Acetanilid and sodium salicylate.
Febralgen: Acetanilid and sodium bicarbonate.
Phenobromate: Acetanilid and potassium bromid.
Phenalgin: Acetanilid, ammonium carbonate, sodium bicarbonate, caffein.
Phenamid: Acetanilid and sodium bicarbonate.

Note that every one of the above wonderful discoveries contains acetanilid. It is a regular bonanza for those manufacturers. Acetanilid costs 25 cents a pound, sodium bicarbonate 3 cents. With the little caffein the mixture costs about 30 cents a pound, and it sells for $16.00!

And now I want to touch on another great nuisance, which brings so much confusion into the poor physician's mind that he simply "don't know what is what," and even the specialist in materia medica often does not know where he is at. I refer to the custom of giving fancy names to well-known, not even patented chemical compounds, and to the questionable practice of giving several different names to the same compound. I will give a few examples, just as they come to my mind:

"Hydrargotin" is a fancy name for mercury tannate.
"Dymal" is didymium salicylate.
"Montanin" is zinc sulphite.
"Chrysolein" is sodium fluorid. "Remarcol" is the same thing.
"Tachiol" is silver fluorid.
"Horit" or "Gorit" is calcium peroxid.
"Calcinol" is calcium iodate.
"Biogen" is magnesium peroxid.
"Musol." is a fake diabetic remedy, which is nothing but salol.
"Anodynone" is a trade name for ethyl chlorid.
"Antimorphin" is a solution of sodium phosphate.
"Katharol," "Lazon" and "Oxydol" are fancy names for a solution of peroxid of hydrogen.
"Intestin" is bismuth-naphthalin benzoate.
"Parietin" is chrysophanic acid.
"Rachitol" is an imbecile name for the suprarenal gland in tablet form.

And if a new preparation appears on the market, the process of which is not or can not be patented, there are sure to come up several brands of it under different names. It is enough to drive one to insanity to try to remember them all. Hexamethylene-tetramine, one of the few really valuable remedies introduced during the last decade, was first brought to the notice of the medical profession under the name "formin." It was soon taken up by Nicolaier, to whom belongs the credit of popularizing it under the name urotropin. After that we got the names "cystogen," "cystamine," "ammonio-formaldehyd," etc., etc., all one and the same thing.

Di-sodium methyl arsenate, a preparation similar to sodium cacodylate, except that the latter is a di-methyl arsenate, is known under the three euphonious and instructive names: "arrhenal," "stenosine" and "neo-arsycodyle."

Iron cacodylate has three aliases: "atarsyle," "ferricodyle" and "marsyle"; thymol carbonate is known under two names: "thyratol" and "thymotal"; magnesium dioxid has two aliases: "biogen" and "hopogan"; airol is also known as "airoform" and "airogen."

What is the remedy? The remedy for this, as for most other evils, is education. It is a false and pernicious theory that error should be left alone; that it will die out by itself. It may in time, but I am sure that error and fraud unattacked will live much longer and thrive much better and have many more followers than if exposed frequently and attacked boldly and unitedly. We need an active, persistent propaganda, a twofold propaganda—propaganda among the laity and propaganda among physicians. The Association should appoint a committee of two or three hundred members, whose duty it should be to write frequently to the daily press on the evil of self-drugging, to enlighten them as to the composition of most of the widely advertised nostrums. It would be still better if every ethical physician constituted himself a committee of one to pursue this work. Show the people that in taking "Peruna," "Hostetter's Stomach Bitters," etc., they are merely imbibing large quantities of whisky. Show them what quack-medicines contain morphin and other narcotics, and the sale of those remedies will diminish materially.

But the physician is just as much in need of missionary work, in his line, as the public is. Let us educate the physician to demand the composition of everything he prescribes. The manufacturer will have to give it, because without the physician he might as well go out of business. And if we are given the formula, let those of us who are competent, examine the product once in a while to see whether it is true to the formula or not. And woe to the manufacturer who gives a false formula or makes false assertions. All his other goods would be ostracized forever. Let the true composition of each remedial preparation be insisted on as a *sine qua non* before prescribing, let our journals print occasionally contributions about the various wonderful discoveries offered to the profession, and all such products as "antikamnia," "thialion," "respiton," "neurilla," "Dad's quinin pills," "emissine," "appendicine," "gynecine," "manola," "sanmetto," "ecthol," "seng," "chionia," "chaparine," "zarcol," "labordine," etc., will disappear from the face of the earth, and will cease to disgrace the pages of our medical journals. Having mentioned medical journals, I can not conclude without saying a few words on the subject of medical advertising.

This is a subject which must be discussed without reserve, and it is a subject which will not be settled until it is settled right. To say that the reading pages have nothing to do with the advertising pages, is sheer hypocrisy; no matter how we may try to get away from it, the fact remains that when we advertise a preparation we give it a quasi indorsement. And even if we don't give it an indorsement, we induce the physicians to prescribe it, we aid in its sale, we encourage charlatanism and fraud, we confuse therapeutics; in short, we aid indirectly in humbuggery. I am not a crank. I am not opposed to new remedies of proved merit, but I assert that the line must be drawn somewhere, and it must be drawn closer than it is at present. We rail at the daily press for admitting filthy medical advertisements and demand that they discontinue the practice. But many of the advertisements in the medical journals are of no better character, and we should certainly give our own journals a thorough cleansing before pointing out filth in the daily press. I am not speaking of such journals as the *Medical Brief*. The object of such journals is filthy lucre, and no filth is too filthy for them. But how respectable journals can admit such articles as emissine, sanmetto, California Fig Syrup, Robert-Hawley's lymph compound, manola, neurilla, seng, chionia, ecthol, antikamnia, Dad's quinin pills, etc., is beyond my comprehension. To preach in the editorial and reading pages therapeutic rationalism, care and discrimination in prescribing, and then nullify the teachings by presenting in the advertising pages a lot of nondescripts of unknown composition, is certainly the acme of absurdity and inconsistency. It is not a whit less inconsistent than the attitude of the *New York Journal,* which prints splendid editorials against the whisky evil and its life-destroying property on one page, and on the next page presents to its readers an array of testimonials of the wonderful life-prolonging virtues of Duffy's malt whisky. No, something must be done in the matter. The advertising pages of ethical medical journals must be made clean, to correspond more or less, at least, with the tone of the reading pages.

In conclusion: Do not misunderstand me; I do not attack all patent or proprietary preparations. Not at all. Our first duty is to our patients. If a patented preparation will do our patients more good than an official one, let us prescribe it by all means regardless of the fact that the manufacturers are making a good profit out of it. I am simply pleading for discrimination. The high-class manufacturers of true synthetics, of products in whose preparation real chemical skill and knowledge are required, or of elegant pharmaceutical preparations, about the composition of which there is no mystery and about which no extravagant assertions are made, who subject their remedies to clinical tests at the hands of competent physicians before they launch them into the market, should be supported and encouraged; the fakers who mix two or three well-known ingredients, christen them with some fancy name and make extravagant assertions for them, should be boldly and fearlessly exposed.

DISCUSSION.

Dr. George F. Butler, Alma, Mich.—I stated at Columbus that we ourselves are to blame for all this. The average physician to-day learns his therapeutics from pharmaceutic houses. The therapeutics of to-day are not equal to the therapeutics of our grandfathers. When the subject of therapeutics is better taught in our colleges and when more time is devoted to it, possibly the physician of the future will be able to prescribe medicines about which he knows something. Materia medica is not taught at all now in some colleges, and is considered of minor importance in others. The student has been taught to look into the microscope for bugs, giving but very little if any attention to the treatment of sick people, and when he enters practice some fellow comes along and says such and such a proprietary preparation is good for so and so, and he prescribes it. I do not know how we are to prevent it either unless students are educated differently. It is really a question whether a medical journal is responsible for its advertisements any more than is *Harper's Magazine* or the *Chicago Tribune*, or any other periodical.

Dr. Caswell A. Mayo, New York City—An improvement in one weak feature in medical education, from the standpoint of the pharmacist, would go far toward solving the problem. That is the practice in hospitals of ordering by numbers. In the average hospital, with the view of economizing the time of the pharmacist, nearly all the internes get into the habit of prescribing certain routine preparations by number, without knowing fully what they are giving in certain conditions. They thus pave the way toward a purely empirical method of treatment. This sort of thing should be avoided. In one college each prescription is written out in full, and it is dispensed separately by the pharmacist; thus the medical students get practice in actually writing prescriptions and the pharmacy students get practice in filling them. It is to be hoped that this individual method of presenting will be more generally adopted.

Dr. C. S. Chamberlin, Cincinnati—Confirming the statements of Dr. Robinson regarding one preparation referred to, I will say that about three years ago Prof. H. M. Gordin analyzed this substance and reported that he found it to be impure phenacetin and I believe he wrote to the editor of one of our most prominent journals calling attention to the fact that they were publishing an advertisement of a fraudulent article, and I myself brought to their notice, through their advertising manager, this fact, but the advertisement still appears in the journal in question. With regard to the proprietary preparations with curious names, the physician is probably responsible for all of them. Dr. Butler admits that he has used every proprietary preparation of iron he ever saw. A few years ago I took charge of the advertising department of one of our largest manufacturing houses, and as I was informed that certain of our leading journals had adopted a rule by which they insisted on having the exact composition of every preparation advertised, I published the formula of each specialty which we advertised in their pages, but I soon found that I was the only one who did so. The manufacturing pharmacist simply supplies the demand of the physician.

Dr. W. W. Tompkins, Charleston, W. Va.—I think the very heads of the profession are largely responsible for the introduction of these preparations. I know very well that when these preparations are brought to me I look over the names of men who have used them, and if a certain list does not contain the name of some one man of particular standing I put the preparation aside, but, on the other hand, if there are endorsements by good men who are recognized as teachers then I am in the habit of giving the preparation a certain degree of confidence. In a certain preparation I noticed that a man had substituted antipyrin for acetanilid. I believe Dr. Robinson stated in his paper that acetanilid is worth 18c or 20c a pound, and I believe phenacetin is worth four or five times that amount. We should all strive to make some original observation as to the effects of medicines, and when remedies are not producing the effect they are asserted to produce, cast them aside. I believe it to be the province of each conscientious physician to endeavor to reduce the number of remedies in the materia medica, and not add thereto. How many of these new remedies are remembered a year after their announcement? Let us do all we can to perfect and simplify therapeutics.

Dr. J. A. Storck, New Orleans—I am inclined to agree with Dr. Butler that the fault begins in the medical college, and that we should teach the student to study the writing of prescriptions, and should teach him materia medica. Even in the best colleges there seems to be a tendency to ignore materia medica.

Dr. J. S. Rawlins, Dancyville, Tenn.—A fault which has not been attended to is the injustice done the licensed pharmacist by prescribing these compounds. I am not a pharmacist, but a physician. The advertisers are using us to introduce their compounds, and very soon they will abandon both physician and pharmacist and deal directly with the patient and advertise through the secular press, and the pharmacist and the physician who give these compounds will be degraded to the position of pedlers of secret or patent nostrums.

Dr. B. C. Keister, Roanoke, Va.—We should make a distinction between secret nostrums and proprietary articles whose formula is known, and we may prescribe the latter, but secret nostrums should not be kept in the drug stores, because no intelligent physician will prescribe them, and they should be relegated to the merchant. In Germany they are not permitted to sell anything of that sort in the drug stores, and it would be a good thing if we could follow that rule in this country.

Dr. C. E. Skinner, New Haven, Conn.—It seems to me that the only effective remedy for this evil is to have men like Dr. Robinson, who understand the composition of these preparations, read papers to us in our meetings and expose their structure. I believe there is more or less danger of the physician at large forsaking the scientific treatises on the materia medica for the literature which accompanies these preparations. There would be no use in appealing to the public through the press, because the average individual is very fond of prescribing for himself, and these concoctions, as well as the literature describing them, are easily obtainable at the druggist's by any one who chooses to ask for them. If the committee of two hundred which has been suggested should be composed of men who were qualified to and who would read papers like this to the balance of us I think it would be a more influential remedy than anything else.

Dr. Hugh N. Leavell, Louisville, Ky.—I had hoped to hear this interesting paper because I am working along the same line. I believe we are perfectly correct in refusing to prescribe any preparation, the formula of which is unknown to us, but we are also, to a very great extent, dependent on the integrity of the druggist. The result is that many times we get a mixture which is not at all similar to the one that was prepared by a very competent pharmacist, and we are much surprised by the variability of the results of our prescriptions, so we should regulate in some way the sale of these so-called synthetic compounds. I had occasion to bring this matter before a local body of men in Louisville some time ago, and I was surprised at the variety of opinion expressed regarding these synthetic compounds. The fact remains that the manufacturer is using the physician as a drummer, and we continue to use any compound placed in our offices for trial, and if peradventure we get some good result we announce it to the profession and then the stock is placed in the corner drug store and sold promiscuously.

Dr. C. S. N. Hallberg, Chicago—There is a great difference in these preparations. Some years ago I made a classification of articles advertised in the leading journals and separated them into twenty-four classes. Some of them were objectionable because they were innocuous; others were decidedly objectionable. This is a work particularly for the pharmacists, and we should endeavor to clarify the situation and correct some of the abuses. There is a rule which requires that before any article can be admitted to the exhibition of the American Medical Association at an annual session, the formula must be placed in the hands of the chairman of the committee on exhibits, yet there are articles advertised in the journals which are not accepted even by sensational newspapers. It has been laid down as a principle that any patent medicine for internal medication, as distinguished from a food, antiseptic, etc., should not receive the patronage of the profession if advertised to the laity, nor should it appear in the medical journals. It seems to me that we should take some steps toward the correction of this evil for the protection especially of the physicians who are often misled into prescribing these medicines by the wily advertisers, only to be afterward used to "boost" them for self-medication to the public.

Dr. B. Pirosh, Chicago—The correction of this evil is one of the hardest problems with which we have to deal. I do not regard as a remedy the conviction of the manufacturing people. The chief trouble lies in the insufficient teaching of pharmacy in our medical schools. Pharmacy and pharmacology ought to be taught more thoroughly, so that the physician at the bedside of the patient shall not hesitate to apply the best remedy he knows, and the best form, too, not being compelled to take refuge in remedies put up for sale by manufacturers and recommended to the learned man by means of pamphlets.

Dr. W. J. Robinson—This question seems to me to be of the greatest importance. I say that a journal is responsible for its advertising pages. If the advertisement does no good and the physician is not induced to prescribe the remedy and the sale is in no way increased then the journal is accepting money under false pretenses; but the manufacturer is a mighty good business man, and if the sales were not increased he would very quickly drop the advertisement, consequently we know that the sales are increased and the advertising pages do aid in spreading the good remedies and the nostrums alike. I am not an extremist. There are some of these remedies to which I do not object, but what I fight against is the attempt to force us to use things about which we know nothing and for which extravagant assertions are made. The physician certainly can not do good if he does not know what he is prescribing and as shown, the composition of many of these things is not even hinted at, so that the physician can not know what he is prescribing.

Clinical Report.

WOUND OF THE MEDIASTINUM.

J. A. GUTHRIE, M.D.
Passed Assistant Surgeon United States Navy.
PORTSMOUTH, VA.

Introduction.—This case came under my care while I was stationed with the Army at Zamboanga, Philippine Islands, and while serving as medical officer in charge of the garrison at the naval station, and of the inhabitants of the Island of Basilan who are subject to the American governor. Basilan is the most southerly island of the Philippines proper, and has about eight thousand inhabitants, mostly Yacan and Mollussa Moros. The building assigned to me as a hospital was a ramshackle, tumbledown, barn-like affair, constructed on piling over the water. Outside of my apothecary, an excellent man, my help was the poorest and most inefficient. Occasionally a young graduate in medicine, who was then in the lumber business at Port Isabella, came to offer his advice; but aside from this meager assistance, I was dependent entirely on my own supervision of the case, day and night.

The Injury.—Lam Ah Chan was employed as a cook by the naval and marine officers stationed in Basilan; he was a civilian employe, not an enlisted man. On the morning of May 29, 1902, he was shot through the chest by a Filipino mess attendant. I saw the man in less than two minutes after he was shot, finding him prone on the floor and unconscious. The lead bullet was imbedded in the wall behind the place where he had stood when he was shot. I picked the bullet out, after carefully measuring its distance from the floor, and taking notice of its course after it had passed through his body and penetrated the planking. The ball entered his body immediately below the third clavicle, grazing that bone, which deflected it downward and inward, passing in this direction out in the median line of the dorsum, at about the upper portion of the body of the fifth dorsal vertebra.

Symptoms.—There was immediate and complete paraplegia and loss of sensation below the point of exit, and at once it was suspected that the spinal column had been seriously injured, or at least that the cord had received some laceration. After the primary shock and unconsciousness had subsided, about an hour after receiving the wound, he vomited the contents of the stomach and nearly an ounce and a half of dark coagulated blood.

Diagnosis.—The possibility of perforation of the stomach and the wisdom of immediate operation was considered, but I decided against it, as I did not consider operation warranted, unless the bullet had zigzagged in its downward course, which would have been more than unusual from the position of its course, its velocity, and the general circumstances attending the case; perforation of the esophagus seemed more plausible. No blood or bloody mucus was expectorated, hence injury to the lungs or bronchii was eliminated, the bullet having escaped these in its course somewhere through the mediastinum. After it impinged against the body of the dorsal vertebra it again deflected, this time upward, as proved by its direction in penetrating the wood above the man's head. Examination of his spinal column revealed no crushing of the bones, as all movements of the back were normally produced, demonstrating no material injury to the bony structure. His quick recovery of consciousness and the minor degree of surgical shock, suggested either an extraordinary amount of vitality or that no harm had been done outside of considerable congestion of the cord with its consequent paralysis.

Course.—His temperature taken at intervals throughout this day remained below 100 F. At about 8 o'clock p. m., he again vomited, this time a watery fluid containing slightly more coagulated blood than was vomited in the forenoon. The pulse became weaker, remaining so for several hours.

May 30. Tympanitis began. The patient passed up during the day a small quantity of coagulated blood, presumably from the esophagus. Catheterization. Bowels emptied artificially. Given nutrient enemata. The patient complains of great pain all over the chest; given morphin sulphate 1/4 gr. with atropin. Highest temperature 100 F.

June 1 and 2. Morning temperature 100; afternoon temperature, 102. Tympanitis disappeared. Continued rectal feeding, catheterization and symptomatic treatment. Patient does not complain of pain in any part of his body or limbs. On June 2 eggnog in small quantity by the mouth was retained without causing distress of any sort. The patient continues to expectorate small quantities of dark coagulated blood.

June 3. Pus formation in bladder discharging through urethra, no history of venereal disease. Irrigation of bladder with warm boric acid solution. Bed sores appeared over sacrum and on left heel. Position in bed is changed as much as practicable, avoiding possibility of internal hemorrhage and gastric distress.

June 5. Morning temperature, 100.4; afternoon temperature, 102.4. Pulse is fuller and stronger; it has never lost its marked regularity. Patient was given small doses of salol, gm. 0.3, t. i. d. He retains with ease and enjoyment eggnog by the mouth, in larger quantity than heretofore, and was given chicken broth by the mouth with good results.

June 6. Paraplegia is slowly ascending, there is no sensation to touch or pain below the sternum and below the point of exit of the bullet in his back. He is given as much nutriment as possible, takes it by mouth often, craves and enjoys semi-solid food.

Up to June 15, when his afternoon temperature ran up to 104.1, there have developed no new symptoms. His temperature during this interval ranged from 100 to 103, bladder symptoms remaining, although discharge of pus was very slight. Small doses of potassium iodid were given in hopes of causing absorption of spinal congestion. The following three days there was a fall in his body temperature and a general improvement. June 19, he had a very restless night, throwing his arms about and complaining of his condition. A constant watch had been kept over him to prevent his Chinese friends from supplying their own means of treatment, as well as to be ever ready to attend to his wants. There is no more pus formation in bladder. Decubitus is increasing in severity, notwithstanding every precaution to relieve undue pressure. He is displaying obstinacy to treatment, which is more than likely stimulated by the conversation of his Chinese friends.

June 20. The heart action being slightly depressed, he was given tincture digitalis, minims 5, by the mouth every four hours. Next day, condition about the same. A mild chill. Morning temperature, 100.2; afternoon temperature, 101.6. Hot water bottles applied under blankets. Hot drinks ad libitum.

There was no particular change in his condition for the next five days, save that the decubitus increased in spite of all effort to avoid pressure. His temperature ranged about 100. The night of June 27, he had a severe chill, with cardiac depression. All drugs except cardiac stimulants were discontinued from June 29, the patient became weaker, a gradual decline set in, and his mind, which up to now had been clear, began to show symptoms of a delusionary character. He refuses his food, and expresses a desire to make away with his life. He was given digitalis, strychnin and brandy, and as much concentrated food as can be retained.

July 3. A large slough was removed from the bedsore over the sacrum, exposing that bone in part and most of the coccyx. Pulse and respiration were becoming weaker, and the patient did not respond to stimulation readily. Morning temperature, 98.6; afternoon temperature, 102. Thorough cleansing of bedsores with pyrozone, and antiseptic protection. Patient gradually grew worse, lost consciousness the morning of July 6, and at 6:40 o'clock p. m. died.

Necropsy.—The following morning a postmortem examination was held, the governor general of Basilan calling in a civilian physician to take notes for the legal proceedings against the Filipino mess attendant. The gist of these notes is somewhat as follows:

Emaciation general; small unhealed abrasions lower right side abdomen and right thigh. Bedsores, both heels, right and left ankles, and over sacrum, latter about six inches in diameter. Appearance of wound of entrance: small raised scar, one inch to left and half inch below internal end of left clavicle. Pleura beneath wound of entrance adherent to apex of left lung. Left lung generally congested. Right lung normal. Some pus formation in lower end of esophagus, could not be absolutely or definitely located, owing to maceration and adhesion of tissues in that region. Appearance of wound of exit: small round scar, one-half inch to left of spinous process and between fourth and fifth dorsal vertebræ. Membranes of spinal cord congested to a marked degree. The cord itself congested to a less degree. There is no evidence of any injury to the bony structure of the vertebral column. Examination of the remaining viscera showed no evidence of any tearing, or inflammatory process caused by the passage of the ball in its course.

The Legal View of Insanity.—The vagaries of judges in dealing with the difficult subject of criminal responsibility are notorious, says our London correspondent. A man may be acquitted before one judge on the ground that he was insane when he committed a criminal act, whereas he would have been convicted before another. Medical evidence they often treat with scant respect, preferring to decide the question by their own lights. The following case is an example: A retired clergyman, aged 62, of Oxfordshire, England, committed no less than seven indecent assaults on girls aged from 11 to 13 within a period of six months. Previously he had had a hard-working and apparently blameless career. The medical evidence showed that there were hardening and thickening of the arteries, especially those of the head, and that he suffered from time to time from dizziness, attended with general mental confusion. There was also defective memory for recent events. He knew right from wrong in the abstract, but did not appreciate the moral significance of his acts in relation to the individuals concerned. The condition was regarded as progressive, and it was stated that the law or moral restraint had no effect on him. He did not understand that he was doing harm to the girls. Dr. Mercier, the eminent alienist, confirmed this evidence, holding that the prisoner was suffering from premature senile decay and both physical and mental deterioration, and that the case was certifiable. The judge pointed out to the jury that the prisoner had filled responsible offices, and had before the trial been regarded as sane. As to the "senile decay" described by the medical witnesses he repudiated the idea that mere decay of the faculties was evidence of insanity or irresponsibility. It lay for the defense to show that the prisoner did not understand that he was doing harm to the children. In conclusion he asked the jury as men of the world to exercise their "common sense." This intimation had the effect evidently desired. After a few minutes consultation they convicted the prisoner, who was sentenced to six months' imprisonment with hard labor. The "common sense" exercise by the judge and jury in this case was, as it often is, only "common ignorance." Common sense is a strong point, and a valuable one in the character of the ordinary English juror. His weak point is want of subtlety, and on an intricate or scientific question he requires the guidance of superior minds, instead of being told to exercise his "common sense." In the celebrated case of Mrs. Maybrick, who was convicted of poisoning her husband with arsenic, "common sense" had much to do with the verdict. An array of scientific evidence, if anything stronger than that of the prosecution, was produced to show that Mr. Maybrick had not died from arsenical poisoning at all. Instead of telling the jury that the prisoner was entitled to the benefit of the doubt on this point, the decision of which in the affirmative, was a necessary preliminary to the verdict of guilty, the judge told them not to pay too much attention to the medical evidence, but to decide the case by the other circumstances, thus reducing an essential point to a merely collateral one. The jury exercised their "common sense," to which the fact that the prisoner had a lover strongly appealed, and convicted her.

WOOD ALCOHOL.

Wood alcohol, which recently has come to be used extensively in the arts and in the manufacture of culinary and medicinal extracts, is a most dangerous substance when taken internally in sufficient quantity. When pure, it has a rather agreeable ethereal odor and a sharp, burning taste, and when ignited burns with a bluish flame, giving an intense heat. It goes under a variety of names, such as wood spirit, methyl alcohol, burning alcohol, Columbian spirit, naphtha and wood naphtha. It is used in the manufacture of ether, chloroform, formaldehyd and methyl chlorid, and also in the preparation of shellac varnish, since it is a good solvent of resinous substances. As there is no revenue tax on wood alcohol, it can be bought for about 50 cents a gallon, whereas grain alcohol is worth $2.60 a gallon, the tax being $2.17 a gallon. This difference in price is a great temptation for the unscrupulous manufacturer of flavoring and medicinal extracts, and it is frequently found that these contain a large percentage of wood alcohol. Thus it has been shown conclusively by Harlan[1] and by Main[2] that essence of Jamaica ginger, peppermint and lemon may contain as high as 75 per cent. of wood alcohol. The cheaper grades of alcohol also frequently contain wood alcohol.

Wood alcohol is, however, a powerful poison, and there is hardly a month in which one does not read or hear of a case of blindness or death resulting from its use or from the use of essence of lemon or Jamaica ginger which had been prepared with it. In the last eight years over fifty deaths due to drinking varying quantities of wood alcohol are mentioned in the literature, but this includes only a small percentage of the deaths which have been caused by that substance. Prior to 1896 only one case was reported. This is probably due to the fact that wood alcohol was not used so extensively then as it is now. Ten of these deaths resulted from drinking essence of lemon, eleven from essence of Jamaica ginger, and the remainder from drinking the pure alcohol, mixed with water. In most of these cases the victims had been out on a "spree," or had bought a quantity of cheap alcohol for a celebration at home, and some of them drank as much as a pint of the alcohol, while others drank ten to twelve bottles of essence of lemon or ginger. Death is said to have resulted, however, from less than two ounces. It is important to note in this connection that the action of methyl alcohol differs widely in different individuals. Perhaps the majority of those who drink it escape without permanent damage, while others may die or become totally blind, even if they have taken smaller doses. The exact mode of the production of death is not known, but the researches of Pohl and of Hunt have shown that methyl alcohol is excreted from the body very slowly. The important discovery has also been made that it is only partially oxidized in the body, and that its administration leads to the formation of a highly toxic acid (formic acid) and probably also formaldehyd. This is an interesting illustration of the fact that the body may convert one poison into another, which is far more powerful than the one that was ingested. Bongers has made the observation that when methyl alcohol is injected into the rectum of an animal some of it and also some formic acid is excreted into the stomach. These substances are presumably reabsorbed, either from the stomach or from the intestine, and some of them again excreted into the stomach, thus forming a "circulation" of methyl alcohol. The result of this "circulation" is that the irritant action of methyl alcohol on the digestive tract is exerted several times. As we shall see below, one of the most marked symptoms of methyl alcohol poisoning is gastrointestinal irritation, and this is probably due in part to the peculiarity of its excretion.

Another very important sequence of drinking wood alcohol is a sudden development of amblyopia, which frequently ends in total blindness. During the last eight years thirty-six cases of amblyopia following the use of wood alcohol in some form have been reported. Twenty-two of these cases followed a debauch during which wood alcohol was drunk; fourteen were caused by drinking essence of Jamaica ginger or lemon, and eight resulted from the inhalation of wood alcohol fumes while shellacking in a large vat or closed room for several days. The last mentioned cases are interesting, because they show how dangerous this drug is when taken for a period of days, even in very small quantities. This is no doubt due to a cumulative action, because the drug is excreted from the system so very slowly. The experiments of Hunt, de Schweinitz and Birch-Hirschfeld show that methyl alcohol may be given to an animal in a single large dose and have a less toxic effect than the same dose of ethyl alcohol. If, however, small doses are given daily to two different animals the one that is receiving the methyl alcohol dies within a week, and may become blind several days before death. The retinæ show marked degenerative changes. The one that is receiving ethyl alcohol, on the other hand, shows no bad effects, and may even gain in weight. If it is killed and its retinæ examined, no pathologic changes are found.

There is some difference of opinion regarding the pathology of methyl alcohol amblyopia. The experiments of Holden, Birch-Hirschfeld and Friedenwald have shown that there is a degeneration of the ganglion cells and macular layers of the retinæ caused by nutritional disturbances, due to the vasoconstrictor effect of the methyl alcohol on the retinal vessels. This degeneration is inevitably followed by a degeneration of the nerve fibers of the optic nerve. Other observers are of the opinion that there is primarily an interstitial optic neuritis, but it seems likely that the first view, which is the more recent, is correct. It is probable, however, that a degeneration of the ganglion cells of the retina and an interstitial neuritis are going on simultaneously.

---

[1] Ophthalmic Record, 1901, x, 81.

[2] Journal of Med. and Science, 1903, x, 26.

The symptomatology of methyl alcohol poisoning presents a very definite picture, and hence it is not difficult to make a positive diagnosis. There may be first great muscular weakness with defective heart action, followed by intense gastrointestinal disturbances with severe nausea and vomiting, intense headache, giddiness, coma and delirium. Some cases die within twenty-four hours, but others recover only to find that they are nearly or totally blind. Some do not lose their sight for several days after they have recovered from their intoxication. These cases of blindness may improve under treatment, but nearly always relapse and remain in that condition. On examination there is found a contracted visual field with absolute central scotomata. The pupils are widely dilated and irresponsive to light. Ophthalmoscopically there is noted a blurring of the edges of the optic discs, positive optic neuritis and later complete optic atrophy.

The treatment of methyl alcohol amblyopia is unsatisfactory. Some cases have improved under free catharsis from jalap, calomel and salines, combined with diaphoresis from hypodermics of pilocarpin. This treatment, however, must be given during the first few days of the acute inflammatory stage if any beneficial results are to be expected. When atrophy begins to show itself strychnin is given hypodermatically in increasing doses until the point of tolerance is reached. Potassium iodid has also been used, but it must be remembered that the prognosis is very bad when signs of atrophy begin to appear. In most cases the affection goes on until complete blindness results, regardless of what treatment is given.

THE N RAYS.

About a year ago Blondlot, a French investigator, while working on polarization of x-rays, made certain observations which led to the discovery of a new variety of rays. He found that there were emitted from his focus tube invisible emanations which would pass through a thin plate of aluminum, could be focused by a quartz lens, and falling on a small electric spark would cause a very noticeable increase in the brightness of the spark. Work on these rays has very rapidly progressed during the past year, so that at present a large amount of data has been obtained regarding them.[1] The work has been limited largely to France and has been done mostly by the discoverer, Blondlot, and by Charpentier, who has developed the subject especially along physiologic lines. These rays have been named N rays from the first letter of the town Nancy, at which place is located the University of Nancy, where Blondlot has been carrying on his researches.

As stated, the presence of these rays was first detected by the effect they produced in increasing the brightness of a small electric spark. Later it was discovered that a small, blue flame would also increase in brightness under their influence. It was found, too, that the presence of the rays could be detected by the effect which they had of increasing the luminosity of phosphorescent bodies. Sulphid of calcium, previously insolated, is very excellent for this purpose and is much used. Even phosphorescent bacteria can be used to detect the rays.

The sources of N rays are numerous, and new sources of these emanations are being discovered continually. As has been stated, they were first observed coming from a focus tube. Later it was found that they are emitted by an Auer incandescent gas mantle and by an ordinary gas flame, but not by the blue flame of a Bunsen burner. The sun emits them in abundance. The Nernst lamp is a prolific source, and the filament continues to emit them for several hours after the light is extinguished. A strip of metal, as silver or platinum, heated to redness is a very abundant source of the rays. Jegou found that a wire carrying an electric current was a source of N rays. He also observed that a simple means of producing them consisted in closing the circuit of a Leclanche element for a time. The liquid of the cell apparently absorbs the rays, and then becomes an energetic source of them. Compression, torsion and strain of many solids will cause an emission of the rays.

Of extreme interest are the physiologic sources of these rays. Charpentier showed that the luminosity of phosphorescent bodies was increased in the vicinity of a muscle, especially when contracting. The same is true for nerves and nerve centers, the brightness varying with the activity of the tissue. By this means it is possible to trace out the course of nerves, such as the median, the ulnar, or the fibers near the skin. The area of the heart and diaphragm can be mapped out, owing to the muscular activity of these structures. Interesting observations were made on the spinal cord. The course of the cord could be clearly traced. When the arm contracts, the emission of rays from the cervical enlargement increases the luminosity of the sulphid screen, indicating an increased activity of this part of the spinal cord. The area of Broca can be mapped out, and a difference observed between the right and left sides of the brain, the latter having the greater effect on the phosphorescent screen. It is interesting to note that inhibitory phenomena, such as the suppression of glandular activity or inhibition of the heart by the vagus, cause an increase in the emission of the rays. This is analogous to the heat given off at the moment of cardiac inhibition.

---

[1] See Comptes Rendus de l'Acad. des Sciences, 1903-04.

The eye is found to be a *prolific source of N rays.* On the other hand, the sensitiveness of the eye is increased under their influence. This effect can be produced also by allowing the rays merely to effect the ocular centers in the brain. In fact, it has been found that the other senses—taste, smell and hearing—all become more acute under their influence. Meyer has shown that the rays are emitted by plants. The active parts, such as the green leaves and the small roots, give them off in abundance. The colorless plants also emit them. He concludes that the emission of these rays is a *function of nutritional activity.* Lambert observed that they are emitted during the action of a ferment on albuminous substances. This may be the real explanation of their occurrence in living tissues, for in the cells processes controlled by enzymes are continually taking place, and, in fact, life may be dependent on such activity.

These radiations may be observed by making use of the following instructions, which we quote from the *Scientific American:*

> A quantity of sulphid of calcium (phosphorescent) is spread on a piece of black cardboard and fixed by collodion so as to form a thin layer; the spot should be at least 0.8 inch in diameter. It is then solarized moderately. The screen is observed in a dim light, darkening the room according to the brightness of the surface. The screen should be observed by indirect vision without looking at it too strongly. It must be remembered that the variations of brightness are produced gradually, with an inertia which depends on the thickness of the sulphid; it is therefore of advantage to diminish the thickness of the layer. The proper precautions should be taken for eliminating outside effects.

We propose to comment further on the subject next week.[2]

THE SCHOLAR AND THE STATE.

The old conception of the scholar as a man given over to debating such questions as to whether or not a crocodile is an insect, or as to how many angels can stand on the point of a needle, has long since passed away. The seclusion of learning within cloistered walls was an inevitable accompaniment of the feudal state of society. If, in that stirring age, a man with a frail body and a thoughtful mind was to live long enough to debate anything at all, it had to be within some such shelter as that afforded by the monastic life. This necessity left its impress on scholarship for generations after the conditions that had brought it into being had disappeared. In the eyes of the world the typical scholar has long been the absent-minded, myopic pedant whose harmless vagaries have been kindly tolerated by his more robust brethren of the real world. The Casaubons and the Dry-as-dusts have excited some amusement and a little pity for many generations.

The modern scholar, fortunately or unfortunately, is not of this type. For better or worse he has been drawn into the current of the life around him, and has come to share in large measure the thoughts and emotions of his fellow-beings. There are those who lament that the leisure of the college professor has given way to a multitude of appointments and engagements strictly comparable to those of a man of affairs; that the professor's study has given place to the "office," and that administrative efficiency rather than scholarly attainment is often the key to professorial advancement. Be that as it may, these features all mark the change that has taken place in the position of the scholar in the world around him. It is a curious fact that while no acute observer can doubt that such a change has occurred, the tradition of unpracticality and worldly inefficiency still lingers. This is particularly true in our own country, where the advice and opinion of the trained man and of the competent scholar are often flouted. Our newspapers, indeed, deliver brawling judgments all day long on all things unashamed, and it may be said of many of our public men, as John Morley said of Macauley, that they "seek Truth, not as she should be sought—devoutly, tentatively, and with the air of one touching the hem of a sacred garment—but clutching her by the hair of the head and dragging her after him in a kind of boisterous triumph, a prisoner of war and not a goddess."

The detachment of the scholar from the state, however, is not even here so marked as it once was. When one of the most eminent among the purely scientific members of the American medical profession consents to become president of a state board of health, when another is appointed director of public health in one of our largest cities, and when another undertakes as a public duty to direct the production of diphtheria antitoxin for a great state, it can no longer be charged that the American scholar is indifferent to the welfare of the state. The scientific man is coming to expect and the state to demand that he shall participate actively in securing for the state the benefit of the discoveries made by its individual members.

We owe our present encouraging outlook in this country very largely to the precept and example of men like Pasteur, Virchow, Koch and our recent guest, Professor Ehrlich. These men have never divorced the life of the scholar from that of the citizen, and while pursuing brilliant and recondite investigations, have still continued to apply to questions of public polity the latest and best results of modern scientific research. The conduct of a model municipal laboratory, the preparation and preservation of material for the exact standardization of diphtheria toxin and antitoxin, and the supervision and guidance of many lines of investigation undertaken for the public good are services of a kind that can be rendered only by a man who stands in the forefront of scientific investigation. They can be rendered only by one who possesses that genius for executive work which is no less necessary for the planning and carrying out of elaborate scientific researches than for the effective control of practical measures directly affecting the public health.

---

[2] Abstracts of articles on the N rays and editorial comments have appeared in The Journal, Jan. 23, 1904, p. 275, abstract 59; February 6, p. 404, abstract 14, and March 19, p. 804, abstract 34.

The services of the investigator to the state are in a measure their own reward, but it has also happened more than once in the history of science that investigations undertaken with a practical end in view have led ultimately to far-reaching theoretical advances. It is a familiar story how Louis Pasteur, a scholar who recognized in full measure his responsibilities to the state, became fired with the ambition to produce a French beer that should equal the best German beers. The outcome of this patriotic ardor was the germ theory of fermentation, which in turn gave birth to the germ theory of disease and revolutionized modern medicine. In the same way it is true that Professor Ehrlich's attempt to obtain an accurate standard for diphtheria toxin and antitoxin has not only successfully accomplished the immediate results sought for, but has led him on to brilliant and far-reaching theoretical considerations, which have already profoundly influenced medical thought and practice, and have opened up vistas of future progress along which the scientific imagination travels in excited anticipation.

THE OCCURRENCE OF THE WIDAL REACTION IN JAUNDICE.

From its earliest use it has been known that certain errors were liable to occur in connection with the Widal test for typhoid, especially with regard to the degree of dilution of the blood to be tested and the time-limit of observation, but these possible errors have been so frequently pointed out and are so easily avoidable that the profession in general has had a great deal of confidence in the reaction. Within the last two or three years a further source of error has been pointed out, namely, the fact that certain cases of jaundice give the Widal reaction, and seemingly with dilutions as high as those generally used in the diagnosis of typhoid fever.

This aspect of the question has been reviewed by Libman[1] in this country, and by Steinberg[2] in Germany. Libman comes to the conclusion that jaundice *per se* does not cause the agglutinating substances to appear in the blood. The reported cases in which jaundice was accompanied with the Widal reaction, he believes, were atypical cases of typhoid or cases in which certain sequelæ of the disease associated with the typhoid bacillus were present. In some cases in which this assumption was positively disproved, he thinks that there was an infection with some germ closely allied to the typhoid bacillus giving rise to the so-called group reaction, or that an improper interpretation of the reaction was made. In four cases of his own in which jaundice was accompanied by the Widal reaction, he was able to demonstrate the typhoid bacillus or some allied organism in every case.

The conclusions reached by Steinberg are very similar to those of Libman. He also points out that jaundice itself is incapable of producing the reaction, this fact being shown both by the negative Widal in many cases of human jaundice, and also by experimental work on the lower animals. Experiments made on animals by injecting them with the different constituents of bile also show that no single constituent or group of constituents of this fluid can cause the reaction. He argues from this that there must be some factor in cases of icterus with the Widal reaction which is not present in all cases of jaundice. His own work and his interpretation of the literature lead him to think that this factor is infection, and he urges that only in infectious icterus is the Widal reaction present. The infectious agent in most of these cases has been shown to be either the typhoid bacillus or a closely allied organism, as the colon, proteus or paratyphoid bacillus. In a few cases, according to Steinberg, this has not been the case, only the ordinary pus cocci having been found. Steinberg lays stress in these cases on the group reaction, just as Libman does, but he calls attention also to the great peculiarities of individual reaction, and thinks that they play an important part in some cases.

The results of these investigations should lead us to exercise greater care in the interpretation of serum reactions in general, and in jaundice cases in particular, though as typhoid cases with jaundice are relatively rare, they are not of surpassing practical importance.

MEDICAL ADVERTISING.

One of the hopeful features of the modern movement in advertising is the announcement from several important magazines that medical advertising is no longer to find a place in their columns. Some time ago we called attention to the fact that the managers of the *New York Times* had issued a card describing their policy with regard to advertising, and refusing to give place in their columns to medical advertisers of any kind. More recently the *Ladies' Home Journal* has made the same announcement. Through agents, it has now become well understood that certain other publications will not renew contracts for advertising space with patent-medicine houses.

This is certainly encouraging. Any sensible man who studies the advertising announcements of the proprietary medicine house, or of the advertising quacks and specialists, can not fail to be impressed with the idea that their only object is to make money and not at all to do any good to the deluded victims, who, urged on by illness, real or imaginary, apply to them with the hope of relief. There was a time when it was considered not improper to advertise lotteries of various kinds, until the amount of cheating and imposition involved in such concerns finally brought them under the governmental power which regulates the passage of matter through the mails. Modern medical advertising would remind one very much of lottery announcements written in alluring style, but with no prizes. Surely they, too, should come under governmental control in the same way.

---

[1] Medical News, No. 5, 1904.

[2] Münchener med. Woch., No. 2, 1904.

Often very little investigation would show that not only do the so-called patent medicines furnished by advertising firms accomplish no good, but that they actually tend at last to do harm. Consumptives, grasping at a straw, and discouraged by the progress of their disease, are tempted to try some of the highly vaunted remedies so alluringly brought to their notice by the newspapers, and as most of these remedies contain materials that disturb the stomach and lock up the secretions, consequently doing harm rather than good, precious time, in which the consumptive by means of fresh air and good food might really have been making headway against his disease, is lost, until finally further resistance to its progress becomes impossible. Only too often does one hear the story that women suffering from carcinoma of the uterus have taken for months some remedy for female troubles, which has delayed their application to a physician until operations are either hopeless or have become much less likely to prove life-saving.

Why, then, should not the restriction with regard to sending improper material through the mails apply to papers containing swindling patent-medicine advertisements as well as to attempts of swindlers of other kinds? Beside, many of them are so worded as to be actually obscene. There is the absurd stuff about sexual weakness, lost manhood, shrunken parts, about loss of virility and the like, sure to be the source of unhealthy curiosity on the part of young people, beside giving rise to many imaginary ailments that for a time make life miserable for young adults. Supposed abortifacients are paraded with the most nauseating publicity.

Reputable papers must, if they would keep their reputation, take up this newer policy of giving their readers truth, not only in the news columns, but also in the advertising columns, and there is seldom truth in patent-medicine announcements.

Unfortunately there are many religious newspapers that still seem to consider that they can accept medical advertisements without belittling themselves. The reason is very evident—money is needed to run a paper, and nowhere is it more plentiful nor can better terms for advertising space be obtained than among the medical advertisers. This very reason ought to stamp such demands as suspicious. Money is easily made where questionable means are employed and where value is not given for payments made. There is absolutely no excuse for the lax attitude of the managing editors of religious periodicals in this matter. Nothing can justify their lending of the influence which their spiritual position gives them to help conscienceless money-makers to exploit the sick and afflicted.

EDDYITES STILL TRIMMING.

Apropos to a recent death in Buffalo, N. Y., from diphtheria under Eddyite treatment, the Christian Science publication committee sends to a lay paper a communication quoting from the by-laws of the Christian Science church to the following effect: "If a member of this church has a patient that he does not heal, and whose case he can not fully diagnose, he can consult with an M.D. on the anatomy involved." This is a concession. It must be a recent one, as we doubt it was included in Mrs. Eddy's inspiration, and there probably will be many more such, including permission for consultation on the physiology, pathology, and even therapeutics in the future. The statement illustrates pretty well the fact that Eddyism is a cult that intends to live, whether its doctrines do or do not, and that the profitess will have her successors, probably in the money-making syndicate, which, we believe, at present controls the concern.

AMERICAN LITERATURE ABROAD.

Dr. C. A. L. Reed, a former president of the Association, is a contributor to the April number of the *Review of Reviews* in an interesting article on American literature abroad. From the inquiry which he has made he finds that the English language is but little cultivated in many continental countries, where American literature is hardly felt as an intellectual stimulus. He suggests a propaganda something on the order of the Alliance Francaise, an institution devoted to the spreading of the French language and literature throughout the world. Such an organization, he thinks, would go far to raise the opinion of American civilization and broaden the culture of the people among whom it existed. Dr. Reed is already known as a literary man by various contributions, and in this case has stepped well outside the medical line, but is as original and interesting in this as in everything else. We may sometime take occasion to notice more extensively the extra-medical contributions of American physicians, which are by no means insignificant, though the part that the profession takes in general literature is hardly recognized by the reading public.

LUMBAR PUNCTURE IN UREMIA.

Although lumbar puncture was originally introduced as a diagnostic rather than a therapeutic measure, cases have not been wanting to show that the proceeding is sometimes followed by improvement in symptoms. It has been frequently noted during the epidemics of cerebrospinal meningitis which have occurred in recent years, that a great improvement occurred in many cases following the removal of spinal fluid, and a similar improvement has also been noted in one or two cases of spinal hemorrhage. Seiffert[1] has just reported some remarkable results from the use of lumbar puncture in uremia. His experience covers only cases of uremia occurring as a complication of scarlatinal nephritis. In several such cases he withdrew from five to thirty cubic centimeters of spinal fluid with excellent results. Cases are reported with cramps, loss of consciousness and stertorous breathing, which, under this treatment, recovered consciousness in half an hour, and subsequently recovered entirely. According to Seiffert, one puncture is all that is generally necessary. He briefly quotes a French writer who has recently treated uremia from kidney lesions other than scarlatinal nephritis by this method, and urges that the results obtained strongly suggest that a more extensive trial be given the method.

THE COAGULATION OF STARCH.

Any question concerning the chemistry of starch can not fail to excite the interest of biologists, especially those interested in physiology. One of the difficult problems in botany has been the manner in which starch is formed and deposited in the cells of plants. Having once been formed its transformations into the dextrins and sugars is better known. Wolff and Fernbach[1] have performed some interesting experiments tending to throw much light on this problem. They have succeeded in extracting from grains in the course of germination, green leaves, etc., a diastase which they call amylo-coagulase, and which has the property of precipitating soluble starch from its solutions. This ferment seems to be an entirely different substance from amylase, which is also present in such substances, for its coagulating power is completely lost by heating to 65 C. for five minutes, whereas the liquefying and saccharifying properties of the amylase is retained even when heated to 70 C. The action, therefore, can not be explained as a reversible process due to amylase. The study of such substances may throw much light on the so-called reversibility of enzyme action, which apparently does not rest on an absolutely secure basis.

THE CORRECTION OF FECAL INCONTINENCE BY SUBMUCOUS INJECTION OF PARAFFIN.

Incontinence of feces is such an annoying complication of a number of disorders that any means promising good results in its correction should be cordially welcomed. In some instances the sphincter still retains some power, but not sufficient to close completely the anal orifice, while in other instances the paralysis of the sphincter is complete. It has been suggested that under the conditions first noted the lumen of the bowel can be narrowed by the injection of paraffin into the submucous tissues on the inner surface of the sphincter, and thus diminish the work of the latter, so that it may be adequate to occlude the remaining lumen. For the cases of the second group various plastic procedures have been recommended, with the object of surrounding the anus with muscular fibers diverted from their natural function, the gluteus maximus and the levator ani being the muscles ordinarily utilized for this purpose. Attempts, frequently unsuccessful, have been made to give the wall of the rectum a valvular action, by dissecting out this portion of the bowel, twisting it on its long axis and refixing it, or by producing a sharp curvature or kink in its lower portion. In two cases of the latter character Mr. H. A. Burgess[2] obtained good results by the injection of paraffin into the lower portion of the rectal wall. The condition was due in the first instance to operations for the relief of anal fistula, and it had not yielded to two corrective plastic operations. The second case, in a boy of seven, was complicated by a prolapse of the rectum, and both conditions had been present from infancy. In the latter, following correction of the fecal incontinence by the injection of paraffin, a plastic operation was successfully performed for the reduction of the abnormally large anus.

THE PROGNOSIS OF TYPHOID FEVER.

It seems certain that the prevalence of typhoid fever has been diminished in no small measure since its exciting cause has been demonstrated, and the necessary steps have been taken to restrict the dissemination of the typhoid bacillus. To this end care in the disposal of the discharges, particularly the feces and the urine, and the insurance of an uncontaminated water supply have largely contributed. It is equally certain that hand in hand with this reduction in the morbidity there has been a lowering of the mortality, as a result of the institution of rational therapeusis, including especially the practice of systematic cold bathing, according to the method of Brand. There is still considerable room for improvement in both of the directions named, and the amount of typhoid fever in a community may be considered as an index of its hygienic intelligence. While the prognosis of the disease in general is thus relatively favorable, it is by no means easy to predicate the outcome in the individual case. It may, therefore, be useful to note the conclusions reached in this connection by Dr. R. E. Sedgwick[1] as a result of observations made in 460 cases of typhoid fever. He finds that the younger the patient the more favorable the prognosis, as mild cases are commonest in the young, while fatal complications are more likely to occur in the old. If the onset of the disease be gradual, the case is likely to prove a mild one; but if the onset be sudden, a severe attack may be anticipated. If the case occurs during an outbreak of typhoid fever, the general character of the outbreak may be of guiding value in prognosis, consideration being given, however, to the age and the constitution of the patient. The degree of pyrexia need not of itself be regarded as unfavorable in a patient of strong bodily health. The pulse-rate is a good indication of the severity of the attack. Sudden changes in the pulse-rate are important as indicating the onset of complications. Constipation is to be looked on as a favorable symptom as contrasted with diarrhea, which is unfavorable. Meteorism is an unfavorable symptom, as it predisposes to perforation. Should perforation occur, operative measures hold out the best chance. Dryness of the tongue is a valuable guide in prognosis. Intestinal hemorrhage occurs chiefly in serious cases. The earlier it occurs the more serious its significance. Early nervous symptoms must be regarded with concern, as an indication either of the severity of the attack or lack of resistance on the part of the patient. Most of the complications —of which perforation, peritonitis and pneumonia are to be considered among the most serious—tend toward recovery. When perforation occurs the only treatment consists in abdominal section, with repair of the lesion. The chances of recovery are better in patients treated in hospitals than those treated in their homes.

VIVISECTION.

In the *Outlook* of April 9 appear two papers on the vivisection problem, both of which are somewhat noteworthy. The first, by Bishop Lawrence of Massachusetts, takes the stand which we think is held by most cultured and enlightened people at the present day, viz., that the benefits that vivisection has accomplished for mankind far outbalance any necessary suffering that may be inflicted on the lower animals; even the single matter of antitoxin in diphtheria, which is quoted by the Bishop, is enough to redeem it from the charges that have been made. The sacrifice of many of the lower animals for the sake of preventing mortality and suffering is justifiable in every sense of the word. The question arises whether this should be regulated, and Bishop Lawrence gives rational objections to the regulation as they appear to him. Dr. Leffingwell's paper is far more temperate than would be expected from the utterances that have been credited to him in the past. He does not deny the utility of vivisection, but claims that the practice of it is abused, and that it is carried on needlessly and with unnecessary cruelty to the subjects; therefore, legal regulation should be required, together with periodical inspection and publication of all experiments. He is studiously temperate in his language, and yet he says a few things which seem to indicate an unjudicial state of mind on the subject. The party, however, with which he trains at the present time certainly would not be fully satisfied with his utterances in this communication. One has only to read the editorials in the little anti-vivisection papers which are sent to nearly every publication in the country to appreciate this fact. Legal regulation, if brought about through the efforts of these individuals, would be more or less influenced by their opinions and scientific research would be seriously hampered. The objections to this are well stated by Bishop Lawrence, and he points out that in Great Britain, under the restrictions now required, the work of scientific research is notably crippled. The editorial notice in the *Outlook* discusses the subject in a thoroughly common-sense point of view, and gives what we believe is the consensus of opinion of thinking people on the subject at the present time. The world appreciates the benefits which vivisection has produced in the relief of disease, the lessening of human and animal suffering, for it is not mankind alone that benefits by these researches. One of the greatest of American writers, in perhaps one of his most striking productions, portrayed the narrowing and dehumanizing effect of a too self-concentrated devotion to a philanthropic hobby. There is nothing more tempting to human weakness than an overestimated self-conscious virtue, and its evil influences on the human character are amply portrayed in modern zoophily. Humanity is the last of their thoughts to all appearances, their sympathies are wrapped up in the lower creatures and the welfare of their own species is hardly considered. Even the ordinary moral requirements are sacrificed to the holy cause which has become their idol, as is shown in the recent misrepresentations abroad, the legal consequences of which were somewhat unfortunate to the leader of the British antivivisectionists. It is to be hoped that the common sense of the majority will not be overcome by the dictation of a fanatic and narrowed philanthropy or zoophily in this matter so important for the advancement of science and medicine and for the welfare of the world.

RATES TO ATLANTIC CITY SESSION.

As we go to press we learn that the Central Passenger Association has granted half rates to the coming session of the American Medical Association. Thus two of the most important passenger associations have granted this rate, and it is likely that the rate will now prevail all over the country.

Medical News.

ILLINOIS.

Societies Favor Heyburn Bill.—Will County and Jersey County medical societies have endorsed the Heyburn pure-food bill, and have signed a petition urging its passage.

Ill and Recovering.—Dr. Ezra H. Ferris, a retired physician of Champaign, is reported to be seriously ill.——Dr. Arthur F. Comings, Rockford, who has been ill since January, resumed practice April 4.

Elgin Hospital to Be Enlarged.—Sherman Hospital, Elgin, which is under the charge of the Elgin Woman's Club, is to have an addition to cost about $20,000. The greater part of this amount has been received by bequests or gifts.

Society's Golden Jubilee.—On April 7 McLean County Medical Society celebrated its semi-centenary by a banquet at Bloomington, at which about 150 were present. Dr. Franklin C. Vandervort, president of the society, was toast master. The following toasts were proposed: "Medical Organization," Dr. Otho B. Will, Peoria; "History of the Society, 1854-1879," Dr. Charles R. Parke, Louisville, Ky.; "History of the Society, 1880-1904," Dr. William E. Guthrie, Bloomington, and "The Future of the Society," Dr. James B. Taylor, Bloomington.

Chicago.

Easter Hospital Collection.—The Easter offerings in the Presbyterian churches of Chicago amounted to about $6,000, which goes to aid the Presbyterian Hospital.

No Prosecution.—The case against "Dr." A. W. Van Bysterveld of Englewood and Muskegon, Mich., was dismissed April 4 for lack of prosecution. He was charged with mistreating a defective girl patient whose father shot the alleged physician in the leg.

Decrease in Death Rate.—During the week ended April 9 562 deaths were reported, 14 less than for the previous week, and 64 less than in the week before, the respective annual rates per 1,000 being 15.03, 15.40 and 16.32. Pneumonia caused 127, or nearly 22.6 per cent., of the deaths; consumption, 65; heart diseases, 49; Bright's disease, 42, and violence, 33 deaths.

Alumni Dine.—Fifty members and invited guests of the Western Alumni Association of the University and Bellevue Hospital Medical College, New York, met at the annual banquet April 11. Dr. David W. Graham was toastmaster and toasts were responded to by Drs. Egbert LeFevre and Joseph D. Bryant of New York City; Dr. Green V. Woollen, Indianapolis, and Dr. John M. Ristine, Cedar Rapids, Iowa. Dr. Charles C. Hunt, Dixon, was elected president of the association.

Increased Mortality.—The record which the Department of Health calls its "sanitary balance-sheet," which at the end of 1894 covered a period of forty-four years—1857-1894—showed that, comparing the mortality of the first and last decades, the deaths from nervous diseases had increased 80 per cent.; from Bright's disease, 94 per cent.; from cholera infantum, 123 per cent.; from pneumonia, 160 per cent.; from bronchitis, 330 per cent.; from heart disease, 360 per cent., and from cancer, 812 per cent.

Decreased Mortality from Nervous Diseases.—Comparing this decade with the previous one, there is shown a decrease of 40.2 per cent. in the mortality from all forms of nervous disease, and of nearly 60 per cent. in the deaths from convulsions. Better hygiene of child life, better milk supply, better knowledge among mothers, sufficiently account for this latter reduction; the Department of Health remarks that it is not so obvious what has caused the reduction of more than one-fourth in the deaths of adults from nervous diseases.

MARYLAND.

Regulation of Barber Shops.—A bill has passed both branches of the legislature regulating the practice of barbering, establishing a state board of barber examiners and providing for the sanitary inspection of barber shops.

Sewerage Bill Passed.—The sewerage bill has passed the legislature after a hard struggle extending over twenty years, and it is ready for submission to the people. It provides for a ten-million-dollar loan. As a six-million-dollar loan has already been provided for improvement of wharves and docks destroyed by the fire, and as the sewerage loan will have to be provided by direct taxation, it will have to be deferred for the present and submitted later to popular vote.

New-Made Laws.—The governor has signed the following bills: Authorizing Hagerstown to build a hospital and to borrow money for drainage system; authorizing Washington County to levy money for a hospital at Hagerstown; state registration of nurses; creating barber inspectors; to incorporate sewer company of Salisbury; to protect the citizens from certain communicable diseases, especially tuberculosis of lungs and larynx; omnibus appropriation bill. The items of the omnibus bill were published in The Journal, April 2, p. 900, April 9, p. 963. It passed with the following changes: Increase appropriation of Baltimore Eye, Ear and Throat Hospital from $2,000 to $5,000 annually, and cut off appropriation of $10,000 for new building; allow $5,000 annually to Union Hospital of Cecil County, provided an equal amount is subscribed privately; allow $5,000 per annum to pay indebtedness of Springfield Hospital for the Insane; allow St. Agnes Hospital $3,000 annually, and Franklin Square Hospital $3,000 annually and $1,000 additional for 1905 to aid in equipment and furnishing.

Baltimore.

Fined for Contempt of Court.—Dr. Frank G. Moyer, for failing to appear as witness, after having been summoned, was fined $27.50, in the Court of Common Pleas, March 29.

Resumes Practice.—Dr. Alexander Hill, formerly fire department physician, has recovered his health after two operations for a large growth involving mouth, throat and neck, and will resume practice.

Physician Wins Suit.—The suit in the Superior Court against Dr. William H. Burch, for alleged incompetent setting and treatment of a broken limb, $5,000 damages being claimed, has been decided in favor of the defendant.

Distinguished Frenchmen Visit Baltimore.—Drs. Jean Louis Faure and Stephen Merlin of France were the guests of Dr. Howard A. Kelly last week. The former, who is a surgeon of note, lectured and operated at the Johns Hopkins Hospital. They left for Florida, April 8, and will make a tour of the country.

Personal.—Dr. H. Lee Franks has resigned as health warden, and the health commissioner has appointed Dr. Clarence P. Erkenbrack to the vacancy.——Dr. Dudley Williams, Boston, will make Baltimore his home.——Prof. George M. Stratton, associate professor of psychology in the University of California, has accepted the professorship of experimental psychology in the Johns Hopkins University, and will enter on his new duties in the fall. He has done much original work on the senses, especially vision, and is also said to be a successful teacher and very effective lecturer.

Deaths and Smallpox.—There were 229 deaths last week, an annual rate of 21.43 per 1,000. The principal causes were consumption, 36; pneumonia, 30; heart disease, 21; Bright's disease, 18; congestion of brain, 11; cancer, 10, and influenza, 8. Two cases of smallpox were reported. The health commissioner has been allowed $1,000 for expenses in fighting smallpox. He stated that there had been 15 cases since January 1, and that 25 persons were now quartered at the quarantine detention barracks who had to be cared for. He expected to have 15,000 persons vaccinated last week.

Medical Club Anniversary.—The Rush Medical Club, a students' club of the University of Maryland, held its fifty-fourth anniversary celebration, March 26. It was founded in April or May, 1850, by seven students as a quiz club, and has kept up an unbroken existence to the present time. The present membership is 20. It is one of the oldest, if not the oldest, of the students' medical clubs in this country. The founder of the club, Dr. William J. Wroth, Baltimore, now in his seventy-fifth year, was present, and addresses were made by him, Drs. Randolph Winslow, Harry Adler, Hiram Woods, W. T. Watson, and A. S. Matthews. Dr. E. F. Cordell read a historical sketch of the club.

Endowment for University Medical School.—The Alumni Association of the Medical Department of the University of Maryland is endeavoring to secure a permanent endowment fund for the school of medicine. The following constitute the present board of trustees of this fund: Judge Henry D. Harlan, Gen. Lawrason Riggs, Dr. Samuel C. Chew, Dr. I. E. Atkinson, Mr. Clayton C. Hall, Mr. Allan McSherry, Dr. Thomas A. Ashby, Dr. Charles G. W. MacGill and Dr. Eugene F. Cordell. Last year the will of Dr. W. H. Crim bequeathed directly to the medical department his entire estate after the decease of certain beneficiaries. The sale of the renowned Crim antiques amounted at that time alone to over $70,000. However, this bequest for many years will not be available to assist the university.

The Rockefeller Gift to the Johns Hopkins Hospital.—As announced last week, Mr. John D. Rockefeller has given $500,000 to the Johns Hopkins Hospital to prevent the curtailment of usefulness of that institution by the losses incurred by the great fire. The money is given outright and will be turned over to the trustees in whatever form they elect. A few days after the fire the matter was brought to the attention of Mr. Rockefeller by Drs. William Osler and William H. Welch, and Mr. Rockefeller sent his attorney to Baltimore to investigate. The attorney spent two days in Baltimore. Nothing further was heard until April 5, nearly two months, and the friends of the institution began to lose heart. On that day a letter was received by Dr. Osler from Mr. Rockefeller, Jr., saying that "in view of the high character of work which the hospital and medical school are doing in medical instruction and research, including the training of nurses, which work, he understands, will be otherwise materially curtailed because of losses," his father had determined to give the amount named to the hospital. Mr. Rockefeller's attorney estimated the losses at about $499,137. It is said that Mr. Rockefeller could not have been more careful in his investigation of the affairs of the hospital if he had contemplated investing money in it for the purpose of gain. Every item in the annual statement of the hospital was carefully gone over by the agent, and every one of its investments was carefully scrutinized. Judge Harlan, president of the board of trustees of the hospital, had prepared a list of well-known philanthropists with a view of appealing to them, but on the advice of Dr. Welch no action was taken until Mr. Rockefeller was heard from. The value of the property destroyed aggregated about $1,300,000, and the net loss to the institution was about $500,000. The gift will not permit of extension of the operations of the hospital; it will not, therefore, be devoted to any special purpose, but to the continuance of the work hitherto done without any curtailment. The burned property will be rebuilt and it is hoped that its value will increase and the good work of the hospital be thus augmented. The credit of this great benefaction is ascribed to Drs. Welch and Osler. It is said that Mr. Rockefeller became interested in medical research through a copy of Dr. Osler's "Practice of Medicine," which was sent him by his agent, Mr. Gates, and that the influence thus exerted led him to the gifts of the $200,000 to the Rockefeller Institute, supplemented later by $1,000,000 for the permanent home of the institute in New York, and also the gift of $1,000,000 made to Harvard University Medical School. The Rockefeller Institute for Medical Research was incorporated in June, 1901, under Dr. Welch as president, and others. The work has been carried on in a number of university laboratories. Last year it was decided to secure a permanent home, and three blocks of land in New York City, extending from Sixty-fourth to Sixty-seventh street, along Avenue A, were purchased for $700,000. Dr. Simon Flexner, formerly connected with the University of Pennsylvania, and Johns Hopkins Medical School, is in charge of it. Dr. Osler is of the opinion that Mr. Rockefeller's gift to the Hopkins Hospital will be followed by other gifts which will enable the work of the hospital to expand. The hospital has not received many gifts, compared with other institutions. Dr. Howard A. Kelly gave about $20,000 for a new operating room and an addition to the gynecological wards. Two ladies of Baltimore gave $6,000 for the tuberculosis work, and Mr. Henry Phipps' recent gift of $20,000 for the same object is fresh in memory. The governor of Maryland and the mayor of Baltimore have both expressed to Mr. Rockefeller the thanks of state and city for his noble benefaction.

MASSACHUSETTS.

Will Filed.—The will of the late Dr. J. Henry Robinson, Southboro, has been filed. The estate is appraised at $76,000.

Golden Wedding.—Dr. and Mrs. Joshua B. Gould, West Somerville, celebrated the fiftieth anniversary of their marriage March 23.

Bequests.—The late Senator Tyner, Holyoke, in his will devised $10,000 each to the Holyoke City Hospital and to the House of Providence Hospital.

Dealers in Impure Milk Fined.—Two milkmen, who sell to stores and private houses, and four store-keepers were fined, April 4, in the Charlestown Court, for the poor quality of the milk in their possession.

Visiting Nurses.—The Instructive District Nursing Association reports that their 15 nurses cared for 7,657 patients in 1903, making 75,000 visits. The expenses were $15,053, leaving a deficit of about $1,300.

The Emergency Hospital in Salem is flourishing. A new wing containing four wards is nearly ready for occupancy, and property in another part of the city has been leased for a branch, which will be established at once.

To Establish Tuberculosis Hospital.—The committee of public charitable institutions has introduced in the Massachusetts legislature a bill to establish the Massachusetts hospital for consumptives with a board of five trustees and an appropriation of $150,000.

Eventual Bequest.—Under the will of Mrs. Hannah K. Grant her interest in a Salem estate is awarded to her sister, after whose death it is to go to the Salem Hospital Corporation. On similar conditions the hospital eventually will receive one-fourth of the residue of her estate.

Personal.—Dr. Orville W. Collins, South Framingham, has been appointed assistant surgeon for the Boston and Albany system, between Riverside and Westboro.——Dr. Edward Roth, Vineyard Haven, has qualified as medical examiner for the northern district of Duke's County.

NEBRASKA.

Schools Closed.—Owing to the prevalence of diphtheria in the country round about Bertrand, the public schools have been ordered to be closed for two weeks.

Mishaps to Physicians.—Dr. Andrew D. Nesbit, Tekamah, is recovering from a serious operation on the ear, performed a month ago.——Dr. Marshall D. Bedal, Blair, has been declared insane, and committed to the insane hospital at Lincoln.

Healer Cast Out.—"Dr." Frank H. Peters, a so-called "magnetic healer" of Beatrice, against whom 30 charges of practicing medicine without a license had been filed, was found guilty on one count and fined $50 and costs. On his promise to leave the state, the other charges against him were dismissed.

Tuberculosis Must Be Reported.—According to a ruling of the State Board of Health physicians are required to report promptly all cases of consumption, so that they may be quarantined when necessary. Any physician, householder or landlord who fails to comply is subject to a fine of $100. Consumption is thus formally included in the list of contagious diseases.

NEW HAMPSHIRE.

Quarter of a Century Old.—The Portsmouth Medical Association celebrated the twenty-fifth anniversary of its organization, April 5, by a banquet, at which 22 were present.

Hospital for Dover.—The executors of the late Arioch Wentworth of Boston have paid over to the authorities of Dover $100,000, for the establishment of the New Wentworth Hospital in that city.

Personal.—Dr. Percy Bartlett has been made instructor in anatomy in the Dartmouth Medical College, Hanover.——Dr. A. E. O'Connell has secured the position of house physician at the Mary Hitchcock Memorial Hospital, Hanover.——Dr. and Mrs. Moses C. Lathrop, Dover, recently celebrated their golden wedding anniversary.

Society for Prevention of Consumption.—The New Hampshire Society for the Prevention of Consumption was organized with headquarters at Concord, "to instruct consumptives in the ways and means to prevent the spread of the infection, and to better their physical condition." Dr. Orlando B. Douglass, Concord, was elected chairman; Dr. John H. Neal, Rochester, treasurer, and Dr. Henri T. Fontaine, Concord, secretary.

NEW JERSEY.

Against Consumption.—Orange has an anti-tuberculosis committee and has started an active crusade against the disease. A free dispensary for tuberculous patients, with daily clinics, is one of the weapons.

Medical Examiners Reappointed.—On March 25 Governor Murphy reappointed the following physicians members of the New Jersey Board of Medical Examiners: Drs. Armin Uebelacker, Morristown; William Perry Watson, Jersey City, and William H. Shipps, Bordentown.

Thousands for Hospitals.—The total appropriation for the State Tuberculosis Sanitarium amounts to $265,000.——Nearly $13,000 has been received for the building fund of the North Hudson Hospital, Union Hill.——The building fund of the Mountainside Hospital, Montclair, now amounts to $36,542.25.

Personal.—Dr. James M. Stewart, Paterson, was appointed a member of the tenement house commission by the governor.——Major Charles R. Blundell, Paterson, surgeon Fifth Infantry, has resigned.——Dr. Talbot R. Chambers, for nine years in charge of the eye, ear, nose and throat department of the Jersey City Hospital, has resigned, and Dr. Wallace B. Pyle has been elected his successor.——Dr. Archibald Mercer, Newark, is recovering from an operation for appendicitis, performed March 30.——Dr. L. Eugene Hollister has been appointed a member of the Newark Board of Health, vice Dr. David L. Wallace, deceased.

NEW YORK.

Smallpox in Buffalo.—Several smallpox cases have been found by the Buffalo Health Department.

Bill for a Letter.—The senate has passed Senator Whitlock's bill to change the name of the Bushwick Hospital, Brooklyn, to Bushwyck Hospital.

Typhoid in Vassar Hospital.—There are 25 cases of typhoid fever in the Vassar Brothers' Hospital, Poughkeepsie. The source of the infection has not yet been determined.

Erie County Society Ratifies.—A special meeting of the Erie County Medical Society was held in Buffalo, April 9, at which the report of the joint committee of conference on consolidating the Medical Society of the State of New York and the New York State Medical Association was approved.

Preventable Epidemics Expensive.—Dr. Daniel Lewis, state health commissioner, calculates the loss in the state during 1903 from five preventable diseases at $94,960,000, estimating the value of a life as $5,000. He does not consider in this aggregate the losses from injury to business due to quarantining localities where infectious diseases exist.

New Health Officers.—The following are among recent appointments as health officers: Dr. William Taylor, Canastota; J. Spencer Purdy, Seneca Falls; Dr. Cyrus Kay, Herkimer; Dr. Charles V. Patchin, Dansville; Dr. John H. Doughty, Matteawan; Dr. I. C. Washburn, Chatham; Dr. Jacob A. Rich, Greenwich; Dr. William N. Campaigne, Green Island; Dr. William T. Tanner, Oneida; Dr. Bentley S. Bourne, Hamburg; Dr. John F. Carleton, Waterloo; Dr. George F. Rogan, Medina, and Dr. Thomas E. Spalding, Salamanca.

Personal.—Dr. Charles W. Pilgrim, superintendent of the Hudson River State Hospital for the Insane, Poughkeepsie, has been appointed president of the State Commission in Lunacy. His acceptance of this position was dependent on the assurance that partisan politics would not shorten his term of office.——Dr. Philip C. Washburn, Watertown, who has been in charge of the High School Typhoid Hospital, has been appointed to the staff of the Manhattan State Hospital, Ward's Island.——Dr. B. C. Johnson, Buffalo, has returned from Jamaica.

Dr. Orton's Semi-Centennial.—The physicians of Binghamton and Broome County, April 5, presented to Dr. John G. Orton of Binghamton a loving cup, accompanied by their greetings and congratulations, on the fiftieth anniversary of his ending the practice of medicine in Binghamton. Dr. Orton's experience is almost unique, for he has passed by more than a score of years the average age attained by physicians, and for a half century has not only been in active practice, but during all these years has not changed his location. His record is most honorable, and the physicians of the state of New York showed their appreciation when in 1890 they elected him president of the

New York State Medical Association. So far as known, there is only one other survivor, beside Dr. Orton, of those who practiced medicine in Binghamton fifty years or more ago. The exception is Dr. N. S. Davis, now of Chicago, who is Dr. Orton's senior by nearly 11 years.

Coroner's Bill Passed.—After four years of constant effort Senator Elsberg's bill to substitute medical examiners for coroners was passed by the assembly almost without objection. The bill does not affect the coroners now in office, except that as each coroner's term expires, a successor is not to be elected. The proposed new statute provides for the appointment of a chief medical examiner and six medical examiners for Manhattan Borough, four for Brooklyn, three for Queens and two each for the Boroughs of Bronx and Richmond. They are to be physicians, and are to be appointed by the mayor, to take office Jan. 1, 1905. They are to be appointed, as far as practicable, from the coroner's physicians in office December 31, 1904. The salary of the chief medical examiner is to be $6,000 a year, and those of the medical examiners are to be $3,500 each. The medical examiners are to be a part of the department of health. They are to assume all the duties of the coroners with the exception that they are to make their reports in all suspicious deaths to the city magistrates, and if an examiner is not satisfied with the result of examination into the cause of death, he is to notify the district attorney and make an autopsy. This new bill will save $60,000 annually to the city in salaries.

New York City.

Bogus Doctor Fined.—"Dr." C. F. Starken was found guilty of practicing medicine without a license and was fined $100.

Gift to Infirmary.—Mrs. John E. Parsons has given $1,000 toward a permanent endowment fund for the New York Eye and Ear Infirmary.

Dr. Conrad Sentenced.—Dr. E. Conrad, who was convicted of attempting criminal operation, was sentenced to state prison for not more than two years nor less than one.

Fire Department Physicians.—Dr. Linnaeus J. Hunter has been appointed surgeon of the fire department for the boroughs of Manhattan and the Bronx, and Dr. James B. Kennedy for the boroughs of Brooklyn and Queens.

Smallpox on Atlantic Steamer.—The steamer *Sicilia*, which arrived off New York from Naples, April 6, with 1,118 passengers, was detained at quarantine with one case of smallpox. The patient was sent to Kingston Avenue Hospital; about 150 of his fellow passengers will go to Hoffman Island for observation, and the steamer will be disinfected.

Contagious Diseases.—For the week ended April 2, 1,265 cases of measles were reported to the sanitary bureau with 28 deaths; 343 of diphtheria and croup, with 39 deaths; 393 of scarlet fever, with 30 deaths; 56 of varicella, with no deaths; 289 of tuberculosis, with 185 deaths; 19 of typhoid fever, with 12 deaths, and 31 deaths from cerebrospinal meningitis were reported.

Annex to St. Luke's Hospital.—Plans for the large pavilion to be built for St. Luke's Hospital have been filed with the building bureau. The new pavilion is to be ten stories high, and will adjoin the present hospital building. It is to be fireproof, fully equipped for general hospital purposes, and is to have a roof garden. It is the gift of the Plant estate, and will cost about $400,000.

Personal.—Dr. William T. Bull, professor of surgery in the College of Physicians and Surgeons, has resigned.——Dr. John B. Knapp was the recipient of $5,000 "in grateful remembrance of his devotion" to the husband of Julie F. H. Nevins.——Dr. John A. Hill has been elected surgeon-in-charge of the eye, ear, nose and throat department of the Harlem Dispensary, vice Dr. Edward Fridenberg, deceased.

OHIO.

License Revoked.—The State Board of Medical Registration and Examination has revoked the license of Dr. S. V. Young, Washington.

Society Endorses Pure Food Bill.—Highland County Medical Society, at its meeting held in Hillsboro, April 6, unanimously adopted a resolution urging the passage of the Heyburn pure food and drug bill, and instructed the secretary to inform Senator Heyburn of its action.

Decrease in Infectious Diseases.—But 48 cases of infectious diseases were reported for the week ended April 10 in Cincinnati. This shows a great diminution from previous weeks, and it is hoped that the various epidemics, typhoid, measles, *and influenza*, that have been raging for so many weeks past, are now at an end.

Cincinnati Hospital Internes.—*The competitive examination for internes to the Cincinnati Hospital for the ensuing eighteen* months was decided at a meeting of the staff, April 9. The winners in order of average were as follows: Jesse S. Wyler, Medical College of Ohio; Joseph L. Ransohoff, Medical College of Ohio; Charles W. Smith, Medical College of Ohio; George S. Mytinger, Miami Medical College; Oscar Behrman, Medical College of Ohio; Oscar Berghausen, Medical College of Ohio; A. E. Osmond, Medical College of Ohio, and E. B. Reemelin, Medical College of Ohio. Alternates were elected as follows: O. D. Barber, Medical College of Ohio; Alvin D. Heavenrich, Miami Medical College; Charles D. Hersel, Medical College of Ohio; and George H. Holt, Miami Medical College. There were in all nineteen contestants, thirteen from the Medical College of Ohio and six from the Miami Medical College.

PENNSYLVANIA.

Isolation Hospital Closed.—For lack of smallpox patients the Hospital for Contagious Diseases at Chester was closed March 22.

Donation to Westchester Hospital.—P. M. Sharles donated to the Chester County Hospital $4,562, to be used in the erection of two receiving rooms and a fireproof elevator and stairway.

Half a Century in Practice.—Dr. Richard Armstrong, who has been in practice 50 years, 48 of which were spent in Lock Haven, was the guest of honor at a banquet given by the medical profession of the city, March 11.

Not Chicken-pox.—Boswell has been having a mild epidemic *diagnosed as "chicken-pox" by the local physicians. The town* is now under strict quarantine on account of smallpox, of which 18 cases have been located.——Several cases of smallpox have been discovered in Clifton Heights, Delaware County. *Every effort is being made by the local authorities to prevent* the spread of the disease.

Personal.—Dr. Jonathan C. Biddle, Fountain Springs, has been appointed assistant surgeon, and assigned to the Eighth Regiment, N. G. Pa.——Dr. Andrew H. Halberstadt has resigned as president of the Pottsville Board of Health.——Drs. J. Guy McCandless and Joseph E. Willetts, Pittsburg, have been reappointed members of the State Medical Board.——Dr. Robert F. Trainer has been appointed smallpox physician of Williamsport, vice Dr. Edward Lyon, resigned.

State Health Conference.—The next meeting of the Associated Health Authorities and Sanitarians of Pennsylvania will take place at Gettysburg, Franklin County, May 26 and 27. This will also constitute the thirteenth annual sanitary convention. The subjects of smallpox and typhoid fever, and of proper legislation for the prevention of the spread of these diseases will be very fully discussed. The registration of vital statistics and its importance to the well-being of the state will be presented in an address by Dr. Cressy L. Wilbur, the statistician of the United States Census Bureau, who for many years has been at the head of the Department of Registration of Vital Statistics of Michigan.

Philadelphia.

Personal.—Dr. Melvin M. Franklin, *a member of the major-surgical* staff of St. Joseph's Hospital, has been appointed to a similar position in the Jewish Hospital.

Summer Course at University.—The Medical Department of the University of Pennsylvania will conduct its usual summer course in medicine, beginning May 9 and extending over six weeks.

Hospital Physicians Chosen.—The trustees of Frankford Hospital, at their meeting April 2, elected the following physicians to the general staff: Drs. William H. Morrison, Charles M. Nassau and S. K. Bolton, to the major-surgical staff; E. E. Kieser to the major-medical staff, and George C. Hanna to the neurological staff.

Bequests.—Simon Muhr, in his will, left a large portion of his estate to benevolent *institutions. The following have* been benefited: Jewish Hospital, $5,000; Jefferson Medical College, $1,000; Philadelphia Home for Incurables, $1,000; Philadelphia Polyclinic, $500; Philadelphia Lying-in Charity, $400; Woman's Hospital, $400; Children's Hospital, $400, and Philadelphia Hospital for Women, $200.——By the will of Herman Stolze, the Episcopal Hospital is a beneficiary to the extent of $3,000.

Hospital Reports.—During the month of March, 79 patients were admitted to the Methodist Episcopal Hospital, and 501 were treated in the dispensary. The total visits made to the dispensary were 1,996. The Medico-Chirurgical Hospital treated 297 patients in the hospital *proper, 418 in the accident* room and 5,218 in the dispensaries.——Germantown Hospital admitted 114 patients and discharged 97. During the month 1,425 cases were treated in the dispensary.——St. Joseph's Hospital admitted 222 patients, with 141 remaining from the month of February, making a total of 363. There were 2,092 patients treated in the dispensary service.

Dr. Faure in Philadelphia.—Dr. J. L. Faure, the eminent *French surgeon and* chief of the major-surgical department in the Cochin and Trousseau hospitals at Paris, has been the guest in this city of Dr. John G. Clark, professor of gynecology in the University of Pennsylvania.' Dr. Clark gave a dinner in his honor, and those present were Drs. William W. Keen, J. Wm. White, John H. Musser, Alfred Stengel, Robert Le Conte, Hobart A. Hare, B. C. Hirst and Charles H. Frazier. Dr. Faure *and* Dr. Howard Kelly of Johns Hopkins University were also guests at a reception given at the Woman's Hospital. In a brief address Dr. Faure paid a glowing tribute to the proficiency of *women physicians in America, and deplored the fact that no* such opportunity for the study of medicine and surgery by women existed in France.

Typhoid Still Raging.—*There were 389 cases of typhoid fever* reported during the week. This is the greatest number ever reported in a similar period. The deaths from the disease reached the record-breaking number of 30, which indicates that the fever is not of a mild type. Last week there were 321 cases and 24 deaths. *That section of the city now being supplied* with filtered water seems to be particularly free from the disease. The health authorities are persuaded that the disease has reached its height. There have been 2,445 cases of typhoid fever reported in the city since January 1. The total number of deaths this week *reached 597, an increase of* 9 over those of last week, and an increase of 97 over the corresponding period of last year. The deaths from pneumonia, which have been abnormally high since January 1, numbered 90 for the week.

GENERAL.

The American Medico-Psychological Association *will meet in* St. Louis, May 30 to June 3, only morning sessions being held. Dr. C. B. Burr, *Flint*, Mich., is secretary.

City Death Rates for the Quarter.—*In the six cities having* populations of more than half a million each, viz., New York, Chicago, Philadelphia, Boston, St. Louis and Baltimore, the five mentioned below, from which statistics are furnished to the Chicago Department of Health, have the following estimated *mid-year populations* (1904), *total deaths during the first* quarter and annual death rates:

City.	Population.	Deaths.	Rate.
New York	3,437,202	21,538	25.22
Chicago	1,950,000	7,675	15.77
Philadelphia	1,408,154	8,205	23.39
Boston	517,950	2,924	18.95
Baltimore	541,000	3,058	22.73

London has a death rate very near that of the lowest one above mentioned. The bulletin of the Chicago Department of Health says that a table of vital statistics for London during 1903 gives the death ratio per 1,000 as 15.62. This is the lowest ever recorded for that city—recent previous years having rates of 17.8 for 1902, 17.4 for 1901, 19.2 for 1900 and 19.5 for 1899. The marked decrease of the last three years is accounted "a fact probably very intimately associated with the mild winters of those years."

FOREIGN.

Prosecution of a Physician by a German Court of Honor.—A certain physician of Dresden has been fined by the medical court of honor for Saxony to the extent of nearly $400 and *costs for contracting* with a charlatan.

Gratuitous Distribution of Antiseptics.—Since 1901 antidiphtheria serum has been distributed free to the poor in the province of Luxemburg. By a recent decree antiseptics are also to be dispensed free of cost to the poor.

Death of a Patient from Negligence.—Dr. H. of Ulm, has been sentenced to three months' imprisonment on account of the death of a patient in a hot air bath in his private sanitarium. The apparatus was not properly managed and the patient was burned to death.

Personal.—Dr. Roswell Park, Buffalo, N. Y., *who is in Germany* attending the German Surgical Congress, was the guest of honor, April 9, at the regular weekly meeting of the Anglo-American Medical Association of Berlin.——Dr. J. M. Swan, *surgeon in charge* of the Canton (China) Hospital, visited the Philippine Islands in March.

The Colonial Congress.—Paris is to hold a congress for general hygiene and international prophylaxis, in the week of May 29. It will be presided over by Prof. A. Charrin, with Prof. Brault of Alger as vice-president. The officials connected with any branch of the government service in the colonies are entitled to membership in the congress *ex officio*.

Anniversary of the First Injection of Calomel.—On April 7, 1864, Professor A. Scarenzio of Pavia made the first injection of calomel. His friends celebrated the fortieth anniversary of this event by presenting him with a gold medal at a banquet tendered him by Italian dermatologists and syphilologists, presided over by Professor Golgi, dean of the university.

Radium-Bearing Ore.—The Austrian authorities have set aside about 50,000 pounds of the radium-bearing pitchblend at Joachimsthal and have divided this amount between the Vienna Academy of Sciences and Professor Curie of Paris, the latter paying for his consignment. Both of the recipients must agree to use the pitchblend and its products solely for scientific purposes and *not market any of it.*

Philanthropy of the Milan Savings Bank.—The Milan Savings Bank has recently distributed nearly two million dollars among the small hospitals throughout the province of Lombardy. This benefits also indirectly the Milan hospitals, relieving *them from the influx of patients from the country* districts. The bank announces that its income is derived in large measure from the country districts, and it wants them to share *to some extent in the profits.*

Memorials to Gussenbauer and Cramer.—The little town in Carinthia where Gussenbauer was born has issued an appeal to his friends and pupils to aid in the erection of a worthy memorial to him there. Subscriptions will be received by *Prof. von Eiselsberg, Vienna 1, Mölkerbastei 5. A portrait* bust is also to be erected in memory of Prof. F. Cramer in the hospital at Wiesbaden, the seat of his labors. Subscriptions are received by the banking house of M. Berlé and Co., Wiesbaden.

Compulsory Disinfection of Rented Apartments.—The authorities of Buenos Ayres are considering an ordinance proposed by the department of health which provides that every householder must notify the board of health the moment when a tenant leaves. The board will then send an inspector and *the place can not be rented again* until the sanitary measures he deems necessary have been taken and the place disinfected. The house owner pays only for the expense of disinfection, but neglect to comply with the ordinance entails a penalty.

Legal Responsibility of Editor for Charlatan Ads.—The Breslau courts have recently inflicted a severe penalty on the advertisement editor of the *Breslauer Generalanzeiger*, a daily paper. He published several ads of a quack named Malisius, who offered to treat all abdominal and sexual affections without interfering with the patient's occupation, and without diagnosis, promising a rapid cure. The court assumed that the editor must have known the fallacy of such promises, and fined him $750. An appeal to a higher court was refused.

Decreasing Numbers of Blind Persons in Prussia.—The proportion of the blind to 100,000 inhabitants has fallen from 92.09 in 1871 to 61.95 in 1900. Out of a total number 4,932 were *blind from early* childhood, 15,183 became blind later, and the history was not known of 1,181 others. Nearly 5,000 are engaged in some occupation, including 1,275 employed on farms or in gardens and 1,263 in wood-working. The number of deaf mutes has slightly increased, although the proportion to populace is a trifle less. More than half are self-supporting, 6,281 in farming and 5,387 in the clothing and cleaning industries. The number of blind mutes has diminished from a total of 288 to 215.

The Common Communion Cup.—The president of the German imperial board of health has recently officially requested the secretary of the interior department to suggest to clergymen that they turn the *communion cup a little* as they pass from one person to the next, thus bringing a fresh place on the rim to the next person communing. He states *that* this is the general custom in Berlin, supplemented *sometimes* by wiping the rim with a napkin from time to time. He begs *that* the secretary will use his influence to have this simple but perfectly adequate precautionary measure generally adopted. One of the Berlin clergymen in whose *church the individual* cup has been introduced gives the history of the movement in favor of the individual cup in a communication *quoted* at length in the *Allg. med. Ct.-Ztg.* for March 19, 1904. He cites extensively from American literature.

Official Warnings from the Carlsruhe Board of Health.—The local board of health at Carlsruhe, Germany, has issued a warning, published in the daily press, against a certain plaster advertised to cure rheumatism, etc. The warning states that the plaster contains lead oxid and hence should be dispensed only in drug stores. The warning further cautions against the "Interstate Department of Health in Chicago," which is sending out circulars claiming to cure all the diseases hitherto incurable or only cured with difficulty. Treatment is by letter and medicine is sent on payment of the fee of $6 to $12. A few months ago the board of health issued a similar warning against the oxygen institute, Novavita, of Berlin. The proprietor of the institute sent an insulting letter in reply to the president of the board of health, and the latter at once instituted suit against him on the ground of defamation in his public capacity. The court decided for the plaintiff, fining the proprietor $7.50 and costs.

The Medical Insurance Company in Belgium.—About three years ago a certain number of physicians in Belgium decided to found an accident insurance company. The aim was to *pocket* the profits of such an enterprise instead of serving merely as the packhorse contract doctors while the profits were being poured into the laps of outsiders. La Médicale, as the new corporation was called, has succeeded beyond all anticipations. It has now nearly $25,000 annual income from premiums, an unparalleled growth in three years for such an undertaking in Belgium. A 5 per cent. dividend may be declared this year, although the medical officers of the society are remunerated much more justly than in ordinary insurance companies. The success of the enterprise is due in large part to Dr. L. Merveille of Chênée, editor of the *Gazette Médicale Belge*, now in its sixteenth year. He with the other nine directors of the society have demonstrated that it is possible to conduct an insurance company on a paying basis without necessarily grinding down its medical officers to starvation remuneration.

Positions for German Physicians in Foreign Lands.—An office was established at Hamburg a few years ago in connection with the local medical society to supply information in regard to medical positions on ships, and in the German colonies and elsewhere. The government has recently formally notified all the consuls and vice consuls and urged their coöperation. The aim is to obtain information of good openings and also to prevent their being usurped by unworthy or incapable incumbents. Question blanks were sent to the consuls to be filled out in case an opening offers and mailed to the Hamburg office. The questions ask the population of the place where a physician is desired; how many Germans or others are there in the place who would be liable to give the newcomer practice; what special qualifications are desirable; familiarity with what languages; what examination will have to be taken; if so, in what language; what hospitals are there and their capacity; would a German physician be able to perform operations in them; how many physicians are there in the place and vicinity; how many German physicians and their names; what is the climate; what epidemic diseases prevail and how is the place best reached, and what are the traveling expenses? How much capital is required for the first settling down, and for support during the first two years? What parties desire the presence of a German physician? Names and addresses of these persons and corporations? Are any inducements offered for a physician to locate there? Is a settled income guaranteed?

The Trance Dancer.—Medical circles in Germany are much interested at present in a certain Mme. Magdeleine G., a Russian, who gives a most artistic dancing performance in a hypnotic sleep. The performance is a musicale, but after being hypnotized by her manager, Magnin of Paris, the sound of the music impels her to dance, while she falls into a cataleptic condition the moment the music ceases. Our current German exchanges contain a number of articles on the subject. Fürer writes to the *Deutsche medicinische Wochft.* that the entertainment seems like a revival of the barbarous practice of exhibiting insane patients to the gaping public. Grünwald in a letter to the *Münchener med. Wochft.* takes much the same stand. He expresses the hope that the Munich Medical Society, which is the first scientific society before which the trance dancer has appeared, will insist on the pathologic character of the performance and *protest against its being permitted,* as a public entertainment. Loewenfeld contributes an article showing the features which stamp the performance as genuine, citing in detail the facts which speak against simulation of the hypnotic condition, or rather of the catalepsy from indirect suggestion. Schlagintweit, on the other hand, is convinced that the hypnotic setting is merely an advertising trick. This difference of opinion and the various discussions have been duly exploited in the lay press, and the *Schlaftänzerin* is the sensation of the day in Munich. The laws in Germany forbid exhibitions of hypnotism for profit, but her manager, Magnin, has succeeded in evading the law to date by some legal quibble. He is a professional magnetic healer and has exhibited the trance dancer only in a few private circles hitherto, mostly in artists' studios at Paris.

LONDON LETTER.

Dr. Jameson.

Dr. Jameson, the leader of the famous raid into the Transvaal, once more, by a turn of the wheel of fortune, occupies a commanding position. He has been appointed prime minister of Cape Colony. The career of this extraordinary man can be compared only with that of the heroes of romance. In turn he has been a successful colonial surgeon, the conqueror of a savage country, a colonial administrator, the leader of a troop of raiders, a felon condemned to death by the Boers, sentenced to imprisonment by his own countrymen, a vigorous parliamentarian, and now at last a prime minister. His disposition is particularly amiable, and not even his opponents deny his honesty. The fact that he has survived the hideous blunder of the raid speaks volumes. Like many other colonists who have made their mark, he is a Scot.

Chicken-pox Mistaken for Smallpox.

A serious outbreak of smallpox is reported in a Yorkshire town. February 10, 9 cases had occurred among young women employed in clothing establishments in Hebdenbridge. After three weeks the disease was thought to have been stamped out, but a number of cases then arose simultaneously, principally in school children. They were supposed to have been infected by one family in whom the disease lingered unknown. Of 45 patients sent to hospital 35 were unvaccinated. Some unnecessary delay in the removal of the patients occurred in consequence of the parents hoping that the disease was chicken-pox. Indeed, some attempted to pass the disease off as chicken-pox because of the supposed slur on their cleanliness. An outbreak of smallpox has occurred in the east end of London. There are 129 cases in hospital and in fifteen days 42 cases have been removed to hospital. Most of the cases have occurred in common lodging houses. The London County Council is on the alert to check the disease and has re-enacted the order, made during the last epidemic, making chicken-pox a notifiable disease so that cases of smallpox which may be mistaken for chicken-pox shall not escape the attention of the health authorities. The council has also appointed two experts as consultants, whose opinion any physician can obtain free of charge in a doubtful case of smallpox.

Plague in Johannesburg.

The latest returns show four fresh cases and one death, all in colored persons. A particularly sad feature is that among the five deaths of Europeans which have occurred since the beginning of the outbreak are those of Dr. Marais, who contracted the disease in the discharge of his duties, and of his wife and daughter, and of Dr. Macneil, who attended them. The sanitary authorities have dealt promptly with the outbreak. A board has been appointed to take charge of all the arrangements. At a special meeting of the town council $25,000 was voted as the initial expenditure. The whole town, especially the native quarters, is subjected to the strictest sanitary supervision. The coolie location, where the outbreak was discovered, will be burned to the ground as soon as the inmates can be removed. Meanwhile a cordon has been drawn round it and all ingress and egress prevented.

Mediterranean Fever.

The annual report of the health of the army on the whole is satisfactory, but Mediterranean fever shows a considerable increase. In forces amounting to 18,470 there occurred 315 cases, of which 238 cases were contracted at Malta.

Medical Graduates' College and Polyclinic.

The fifth annual meeting of the Medical Graduates' College and Polyclinic has been held. The report is most satisfactory and shows that a successful effort has been made to overcome the serious financial difficulties of the institution. A great accession of members has recently taken place and the total now reaches 927. Four sessions of practical classes, each of six weeks' duration, and a vacation of three weeks were held. Three hundred and fourteen clinical investigations were carried out in the laboratory and this department is receiving steadily increasing support. A course of 186 lectures by various men of eminence has been established and is open to members without extra fee.

A Revaccination Bill.

A revaccinantion bill, promoted by the Imperial Vaccination League, has been introduced into the house of commons by Sir John Batty Tuke, M.D. It provides for the revaccination of all children between the ages of 12 and 13 except those who obtain certificates of exemption in the way provided by the act of 1898 or those who may be exempted on medical grounds. The bill is backed by all the medical members of parliament and by other prominent politicians. Among the reasons given for the passing of the bill are the following: By the age of 12 the protection of primary vaccination is greatly diminished. Protection against smallpox by revaccination would be much cheaper than by providing costly hospitals and attempting to deal with epidemics by isolation. The provision of smallpox hospitals in London has recently cost $4,500,000 and the current expenditure is enormous.

Correspondence.

That "Neurasthenia" Foolishness.

Toledo, O., March 30, 1904.

To the Editor:—Your editorial of March 26 under the title "The Tyranny of Words in Medicine," wherein you refer to the unscience of the word neurasthenia as at present used in medicine, is in harmony with an extreme tiredness which has grown on me from the use of that word. The word started high in the medical profession and so was entitled to respectful consideration, but I believe that it long since had its full mete of attention, and I believe too that now both the physician and the sick man are better off without it.

I feel relieved and grateful to any one who gives even a plausible cause, like "eye strain," for the conglomeration of nervous symptoms and their functional manifestation which are now bunched together under that alleged nosologic entity. Within my time this varying jumble of symptoms has been said to be "uric acid diathesis," chronic malaria, and "autointoxication," and have been indexed under these different heads. For a time each of these substitutions of one unknown quantity for another has satisfied the medical mind, or at least has furnished a working hypothesis for the treatment of the sick. But no one ever succeeded in curing a patient by treating the symptoms, not any more than a child can be cured by treating the train of nervous symptoms which are dependent on an irritating prepuce. Spectacles would do such a child no good even though the eyes had become secondarily affected, and it is equally as silly to try to cure a similar complex of symptoms in one who is suffering from defective vision without giving him appropriate lenses.

A diagnosis of neurasthenia is on a level with a diagnosis of "neuralgia," and a diagnosis of "cutting teeth." I am not an oculist, but I think that articular rheumatism is a very common affliction of astigmatic school children. I think, too, that such children have better health during vacation, when they, presumably, use their eyes less.

I do not make any money by sending patients to oculists, but in obscure nervous troubles, or in unaccountable functional derangements of any kind I have learned, or possibly it has become a hobby of mine, to have the eyes examined before prescribing for them. Of course, I do not intend to say that I do not look for other exciting causes for the troubles, nor that I always find the real cause; nor that when the oculist says the patient needs lenses that the symptoms always rapidly disappear. What I am trying to say is that I do not make a diagnosis of neurasthenia. I would rather any time say outright that I do not know. To diagnose neurasthenia is to beg the question, and what is worse and still more unscientific, is to say that neurasthenia is the cause of some local trouble, like "asthenopia," for instance.

J. L. Tracy.

The Common House Fly as a Carrier of Typhoid.

Chicago, March 29, 1904.

To the Editor:—In The Journal, March 10, 1903, I published the report of certain investigations carried on in the Memorial Institue for Infectious Diseases, which apparently showed that the bacillus of typhoid fever could be found on the legs of flies which had visited vaults containing typhoid discharges. The organisms which were isolated, five in number, corresponded morphologically and culturally with the bacillus of Eberth and also were agglutinated by the serum of a rabbit immunized against the latter. The weak link in the chain of evidence, however, was the fact that agglutination could not be obtained in dilutions higher than 1-200. It is true that two control organisms, isolated from the blood of typhoid patients, also failed to agglutinate in higher dilutions, but the opinion generally held now, that it is only sera of high potency which will serve to differentiate the typhoid bacillus from closely allied organisms, renders this control inadequate. At that time no stronger serum was available and as it was desirable, for many reasons, to publish the report as soon as possible, the additional experiments needed to establish the identity of the bacillus isolated from flies were necessarily postponed. Later in the spring the serum from an immunized goat was obtained with the following result: (The organisms are named as in the original report.)

Control	1-7,500 + 1-10,000 incomplete.
A 1	1-7,500 + 1-10,000 incomplete.
A 2	1-7,500 + 1-10,000 incomplete.
A 3	1-5,000 + 1- 7,500 incomplete.
P 1	1-5,000 + 1- 7,500 incomplete.
P 2	1-7,500 + 1-10,000 incomplete.

These tests were all made macroscopically, in test tubes.

The immunization of guinea-pigs with the different bacilli was interrupted by an absence of several months, and when it was resumed in the fall the two tubes containing the cultures of A 3 and P 2 had become contaminated during frequent transplantations and the work had to be confined to the remaining three.

At first Pfeiffer's method was followed; one-half a platinum loop of an agar culture killed by heat was injected subcutaneously; five days after, the same dose was injected into the peritoneum and then, at intervals of five days each, two half-loopfuls of living bacilli were injected into the peritoneum. The animals were bled in twelve to fifteen days after the last injection, but the sera of all four (the fourth being the control, injected with typhoid bacilli), proved feebly agglutinative, the action ceasing after the dilution of 1-150 had been reached. One c.c. of a twenty-four-hour bouillon culture was then given by intraperitoneal injection, and after a week 2 c.c. and the animals bled a second time. The sera now agglutinated in dilutions of 1-800 or more as follows:

Control serum	+ Typh. b.	1-1,000 + 1-1,500
Control serum	+ A 1	1-1,000 + 1-1,500
Control serum	+ A 2	1-1,000 + 1-1,500
Control serum	+ P 1	1-1,000 + 1-1,500
Serum A 1	+ Typh. b.	1- 800 + 1-1,000
Serum A 1	+ A 1	1-1,000 + 1-1,500
Serum A 1	+ A 2	1- 800 + 1-1,000
Serum A 1	+ P 1	1-1,000 + 1-1,500
Serum A 2	+ Typh. b.	1- 800 + 1-1,000
Serum A 2	+ A 1	1-1,000 + 1-1,500
Serum A 2	+ A 2	1-2,000 + 1-2,500
Serum A 2	+ A 2	1-1,000 + 1-1,500
Serum P 1	+ Typh. b.	1-2,000 + 1-2,500
Serum P 1	+ A 1	1-1,000 + 1-1,500
Serum P 1	+ A 2	1-1,000 + 1-1,500
Serum P 1	+ P 1	1-1,500 + 1-2,000

The variations found in these agglutinative tests are no greater than may be observed if different strains of typhoid bacilli are tested with the same serum. For instance, a certain typhoid culture which had been in use for some months in the laboratory was agglutinated by the serum of the control animal only in a dilution of 1-800, but the serum of animal P 1 agglutinated it in a dilution of 1-1,200.

So far, therefore, as our present understanding of the question goes, the three organisms (if not the five) isolated from the legs and bodies of the flies which were caught in and around the privy vaults and yards of houses containing typhoid patients, have been proved to be true typhoid bacilli.

Alice Hamilton.

The Vienna Anglo-American Medical Association.

Vienna, March 29, 1904.

To the Editor:—The Anglo-American Medical Association of Vienna was organized Feb. 6, 1904, with 56 members, and now has a membership of 80. The object of the organization, as stated in the constitution, is to promote social intercourse among the English-speaking medical men studying in Vienna, to advance the scientific interests of its members and to aid in quickly acquainting the newcomer with the medical and scientific courses given in Vienna.

The association meets every other Saturday evening for supper, after which there is a scientific and social meeting, the former consisting of an address on some medical topic by one of the professors or teachers connected with the university. Professors Ortner and Finger and Private-Docent Sternberg have delivered very interesting and instructive addresses.

Inquiries addressed to the secretary, Dr. F. G. Harris, 8 Schlösselgasse No. 2, Vienna, will be cheerfully answered.

F. G. Harris.

[The officers of this organization were mentioned in The Journal, March 19, 1904, p. 779.—Ed.]

Anesthol.

New York City, March 29, 1904.

To the Editor:—We beg to state that the use of the name of Dr. Willy Meyer of New York on the label of the new anesthetic anesthol was introduced without his knowledge, though in entire good faith on our part.

At his request the label has been changed and, in order to protect the medical profession against unreliable imitations, it will henceforth bear the name of Dr. Weidig, the originator of the new compound.

Queries and Minor Notes.

Anonymous Communications will not be noticed Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE DOCTOR'S THREE FACES.

Brooklyn, N. Y., March 31, 1904.

To the Editor:—Can you give me the verse in which occurs the reference to the three faces of the doctor; one when it looks like an angel's, one like a god's and the other like the devil's? R. T.

Answer.—Our correspondent probably refers to the epigram written by Enricus Cordus, a physician of the early part of the Sixteenth century. It was in Latin as follows:

> Tres medicus facies habet; unam quando rogatur.
> Angelicum; mox est, cum juvet, ipse Deus.
> Post ubi curato, poscit sua prœmia, morbo
> Horridus apparet; terribilisque Satan.

This is freely translated as follows:

> Three faces has the doctor; when first sought,
> An angel's—and a God's, the cure half wrought;
> But when the cure complete he seeks his fee
> The devil looks less terrible than he.

WHERE ARE WE AT?

A new avenue of usefulness in life has opened before the man who fails to make a success in some other way. We can not question the matter, since it comes with the authority and weight of New York and Boston literary culture behind it. In the *Boston Medical and Surgical Journal*, March 31, in an article on "The Partial Passing of Neurasthenia," by Dr. C. L. Dana, New York, occurs this sentence: "They (cases of dementia precox) are seen in college men and young professional men who break down suddenly after starting out brilliantly and are never heard of, becoming perhaps, breadwinners and fathers and mothers of families, but never amounting to anything, and always working at a disadvantage."

REVOKING OF LICENSES.

Dr. S. M. Mason, Clarksburg, W. Va., asks for information regarding the revoking of licenses by the medical boards of the different states for such causes as malpractice, immoral conduct or criminal practices.

Marriages.

Eugene H. Pool, M.D., to Miss Esther Hoppin of New York City.

J. T. Bradbury, M.D., to Miss Alerta Kissick, both of Cody, Wyo., April 4.

Kellogg Speed, M.D., to Miss Adelaide Brown, both of Chicago, April 12.

John C. McEnery, M.D., Jacksonville, Ill., to Miss Mary Milligan of Chicago.

Paul Louis Reiss, M.D., to Miss Louise Castanedo, both of New Orleans, April 6.

Otto Baumrucker, M.D., to Otilia Olga Zelezny, M.D., both of Chicago, April 7.

Clarence Haecker, M.D., Marshalltown, Iowa, to Miss Anna May Zelezny of Chicago April 7.

Walter E. M. Ranchous, M.D., to Miss Bertha May Buchman, both of Columbus, Ohio, April 7.

John Nuttall, M.D., Newcastle, Ky., to Miss Anna Brinker of Wilmette, Ill., at Hammond, Ind., April 5.

Jacob Webber, M.D., Louisville, Ky., to Miss Ethelyn Mack of Kansas City, Mo., at Bardstown, Ky., March 28.

William Calvin Kennerdell Berlin, M.D., Cleveland, Ohio, to Miss Bessie Lee Koen of Mannington, W. Va., April 6.

Deaths:

Charles Gilbert Chaddock, M.D. University of Michigan, Ann Arbor, 1885; of St. Louis; a member of the American Medical Association, the American Medico-Psychological Association, and St. Louis Medical Society; fellow of the American Academy of Medicine; professor of nervous and mental diseases Marion-Sims-Beaumont Medical College, surgeon of the Seventh Michigan Volunteer Infantry during the Civil War, died at his winter home in Berkeley, Cal., April 1, aged 76.

Crawford E. Fritts, M.D. College of Physicians and Surgeons, New York, a member of the American Medical Association, New York State Medical Association, New York State Medical Society, visiting surgeon of Hudson City Hospital, consulting physician to the Hospital of the State House of Refuge for Women, died April 6 at his home in Hudson, N. Y., from neuralgia of the heart, aged 53.

John Higgins, M.D. Indiana Medical College, La Porte, Ind., 1846, during the Civil War surgeon of the Twelfth Illinois Volunteer Cavalry, and surgeon-in-charge of the General Hospital, Camp Stoneman, near Washington, D. C., died at his home in Crown Point, Ind., where he had practiced for 40 years, from apoplexy, April 6, aged 82.

Dennis Denman Loop, M.D. University of Buffalo, N. Y., 1864, of North East, Pa., sometime president of the Erie County Medical Society and of the Medical Society of Northwestern New York, and a member of the Medical Society of the State of Pennsylvania, died, April 2, from apoplexy, after an invalidism of six years, aged 76.

Judson Wade Garnett, M.D. College of Physicians and Surgeons, Baltimore, 1871, a member of the American Medical Association and North Texas Medical Association, and local surgeon for the M., K. & W. and St. L. & S. W. railways, died recently at his home in Greenville, Texas, aged 56.

Louis A. Crist, M.D. University of Pennsylvania, Philadelphia, 1896, a member of the Medical Society of the State of Pennsylvania and the Lackawanna County Medical Society, died at his home in Scranton, Pa., April 3, from pneumonia, after an illness of ten days, aged 33.

Douglas J. Cameron, M.D. University of Edinburgh, Scotland, of New York City, died in Phoenix, Ariz., March 14, aged 31. He practiced chiefly among the east side poor, and was commonly known as the "Good Samaritan."

Josiah C. Campbell, M.D. Howard University, Washington, D. C., 1877, formerly a member of the Vermont legislature, died at his home in Attleboro, Mass., March 24, from pneumonia, after a short illness, aged 60.

George G. Griffin, M.D. Jefferson Medical College, Philadelphia, 1859, a surgeon in the Confederate service during the Civil War, died at his home in Covington, Ga., April 4, after an illness of two weeks, aged 69.

Floyd F. Hollister, M.D. Syracuse University (N. Y.) College of Medicine, 1900, of Weedsport, N. Y., died, March 28, at the home of his father in Mexico, N. Y., from influenza after an illness of one week.

John Albert Gray, M.D. University of Michigan, Ann Arbor, 1902, of Scottsville, Mich., died in Dallas, Texas, where he had gone in hope of regaining health, April 3, from pulmonary tuberculosis, aged 28.

Francis Rush Skinner, M.D. Castleton (Vt.) Medical College, 1854, the earliest resident physician of Eau Claire, Wis., who retired from practice in 1884, died at his home in Eau Claire, March 28, aged 72.

Charles M. Garrison, M.D. College of Physicians and Surgeons, New York, 1884, of Salt Lake City, state medical inspector, died in Salt Lake City from cerebral meningitis, March 26, aged 45.

Peleg Wadsworth, M.D. National Medical College, Washington, D.C., 1863, for many years city physician of Malden, Mass., died suddenly at his home in that place, April 2, from heart disease, aged 69.

Elisha Crowell, M.D. University of Pennsylvania, Philadelphia, 1851, who had practiced in West Philadelphia for 53 years, died at the home of his son in Philadelphia, April 5, aged 75.

Robert A. Warnock, M.D. University of Nashville, 1857, a surgeon in the Confederate service during the Civil War, died at his home in Inverness, Fla., from paralysis, January 30, aged 72.

John L. Gleason, M.D. Harvard University Medical School, Boston, 1866, of Hannibal, Mo., died at a sanitarium in St. Louis, March 30, from disease of the stomach of long standing, aged 66.

J. Carroll Monmonier, M.D. University of Maryland, Baltimore, 1866, died at his home near Franklin, Baltimore County, April 6, aged 57. He was a member of the Maryland legislature in 1892.

John Philip Young, M.D. Medical Department of the University of Iowa, Keokuk, died suddenly at his home in Oakdale, Cal., March 14, from pulmonary hemorrhage, aged 61.

Atticus Grattan Whitehead, M.D., twice president of the Medical Association of Georgia, died at his home in Waynesboro, Ga., March 24, after a long illness, aged 63.

Addison W. Taylor, M.D. University of Pennsylvania, Philadelphia, 1871, died at his home in Beverly, N. J., April 3, from paralysis, after an illness of five weeks, aged 58.

Edward A. Walter, M.D. the University and Bellevue Hospital Medical College, New York, 1899, died at his home in New York City, February 27, from pneumonia.

Charles R. Sexton, M.D. Tulane University, New Orleans, 1875, died from pneumonia at his home in Birmingham, Ala., April 2, after an illness of three weeks, aged 58.

William H. Heller, M.D. Rush Medical College, Chicago, 1855, died recently at his home in Abingdon, Ill, aged 82. He was the oldest practitioner in Knox County.

Jacob B. Engle, M.D. Indiana, 1897, of Lagrange, Ind., who was recently committed to Longcliff Asylum, Logansport, died in that institution recently, aged 66.

Henry G. Souder, M.D. Hahnemann Medical College, Philadelphia, 1875, died suddenly at his home in Woodstown, N. J., April 1, from apoplexy, aged 58.

T. T. Ferree, M.D. College of Physicians and Surgeons, Baltimore, died at his home in Asheboro, N. C., March 20, after a lingering illness, aged 52.

George H. Hammond, M.D. New York University, 1872, died at his home in Freeport, Long Island, N. Y., March 28, from pneumonia, aged 57.

William A. Eutravella McKee, M.D. University of Maryland, Baltimore, 1883, died at his home in New York City, March 28, from pneumonia.

A. Smith Mays, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1875, died at Wharton, Ohio, March 29, from dropsy.

Jeremiah S. Hetrick, M.D. Washington University School of Medicine, Baltimore, 1873, died recently at his home in New Freedom, Pa.

Edson S. Munger, M.D. University of Vermont, Burlington, 1882, died at his home in Windsor, Vt., from pneumonia, March 29, aged 47.

Walters Burrows, M.D. College of Physicians and Surgeons, New York, retired, died at his home in Elizabeth, N. J., April 2, aged 75.

John D. Young, M.D. Penn Medical University, Philadelphia, 1864, died suddenly at his home in Winthrop, Mass., March 25, aged 62.

John S. Powell, M.D. Jefferson Medical College, Philadelphia, 1853, of Occoquan, Va., died at Alexandria, Va., March 12, aged 74.

James D. Archer, M.D. Starling Medical College, Columbus, Ohio, 1884, died at his home in Holgate, Ohio, February 26, aged 45.

Andrew J. Cunningham, M.D. Columbus (Ohio) Medical College, 1888, died at his home in Jasper, Mich., March 4, aged 54.

Robert Mackinlay, M.D. University of Edinburgh, Scotland, 1882, died at his home in Santa Barbara, Cal., February 28, aged 43.

William H. Latham, M.D., for 52 years a teacher of the deaf and dumb, died at his home in Indianapolis, April 5, aged 89.

H. F. Myers, M.D. Kentucky School of Medicine, Louisville, 1883, died at his home in Rosepine, La., March 7, aged 60.

Edward J. Fowlkes, M.D. Medical College of Virginia, Richmond, 1856, died at his home in Winterpock, Va., March 9.

Luther D. Scherer, M.D. Chicago Medical College, 1875, died at his home in Los Angeles, Cal., March 2, aged 57.

Vastine C. Lunn, M.D. Rush Medical College, Chicago, 1896, died at his home in La Grange, Texas, March 5.

Felix Fettig, M.D. Detroit Medical College, 1877, died at his home in Detroit, Mich., March 11, aged 68.

Alfred B. Kibbe, M.D. University of Buffalo, 1880, died at his home in Seattle, Wash., March 27.

C. H. Roberts, M.D., died suddenly from heart disease at his home in Wolfe City, Texas, March 26.

James H. Bryant, M.D. Indiana, 1897, died at his home in Gentryville, Ind., March 22, aged 82.

Marion Lewis Mayo, M.D., late of Huntington, W. Va., died at Richmond, Va., April 6, aged 82.

William Mulherne, M.D., died of heart disease at the home of his father in Philadelphia, April 9.

Philip D. Carper, M.D. Iowa State University, died at Los Angeles, Cal., March 4, aged 41.

William D. Hill, M.D. Indiana, 1900, died at his home in Martinsville, Ind., March 22.

Linus Squires, M.D. Iowa, 1880, died recently at his home in Mitchell, Iowa, aged 72.

Joseph B. Frazier, M.D., died at his home in Baltimore, March 5.

Book Notice.

THE COMMONER DISEASES OF THE EYE, How to Detect and How to Treat Them. For Students of Medicine. With 250 Illustrations, Many of Them Original, of Which 7 are Colored Plates. By Casey A. Wood, C.M., M.D., D.C.L., Professor of Clinical Ophthalmology in the University of Illinois, and Thomas A. Woodruff, M.D, C.M., L.R.C.P. Lond., Professor of Ophthalmology in the Post Graduate Medical School, Chicago. Cloth. Pp. 499. Price, $1.75. Chicago: G. P. Engelhard & Co. 1904.

A better title for this book would have been "Ophthalmology for the General Practitioner," for this would have expressed exactly what it is. The authors have done more than to simply discuss the common diseases of the eye; they have given its anatomy and physiology, especially the latter, and the methods of examination, and in fact have treated the subject from the broad standpoint of the needs of the physician. The first three chapters are devoted to the examination of the eye and to errors of refraction and their correction. Then follow chapters on the common diseases of the eyelids, the conjunctiva, the cornea, the iris, the crystalline lens, etc. The chapter on "How to Preserve the Eyesight" is especially worthy of note. In it are considered the questions, at what age a child should be sent to school, the arrangement of school rooms, the color of window shades, arrangements of seats, blackboards, etc., from the standpoint of the pupil's eyesight. "Ophthalmology in General Medicine and Surgery," "The Ocular Complications of Certain Systemic Diseases," Headache, etc., from Eyestrain," and "Remedies in Ophthalmic Practice," are the subjects of other chapters, and indicate the practical scope of the work from the standpoint of the general practitioner. Every subject is discussed fully, yet while the book contains nearly 500 pages, it is free from padding It is scientific, but the matter is presented in such simple language, and in such an elementary manner, that even a layman could understand it The book is well illustrated, and an unusually complete index adds to its value On the whole, for the general practitioner, it is one of the most satisfactory books on the eye of which we know

State Boards of Registration.

COMING EXAMINATIONS

Illinois State Board of Health Chicago, April 25 27, and East St Louis, May 4 6 Secretary, J A Egan, Springfield

Board of Medical Examiners for the State of Texas, Austin April 21 23 Secretary, M M Smith, M D Austin

State Board of Medical Examiners of Iowa, April 14 15 at Keokuk April 20 21 at Des Moines, May 2 3 at Sioux City Secretary, J F Kennedy, M D, Des Moines

Nebraska State Board of Health, Lincoln, April 21 23 Secretary, Geo H Brash, M D, Beatrice

Nevada State Board of Medical Examiners Carson City, May 2 Secretary S L Lee M D, Carson City

Louisiana State Board of Medical Examiners, Tulane Medical College New Orleans, May 6 7 Secretary, F A Larue, M D New Orleans

Mississippi State Board of Health, Jackson May 10 11 Secretary, J F Hunter, M D, Jackson

State Board of Medical Examiners of South Carolina, State House, Columbia, May 17 Secretary, S C Baker, Sumter

University of the State of New York, State Medical, Homeopathic and Eclectic Boards, New York, Albany, Buffalo and Syracuse, May 17 20

Board of Medical Examiners of the State of North Carolina, Raleigh, May 18 Secretary, G W Pressly, Charlotte

The Ohio State Board of Medical Examiners will hold examinations at Cincinnati, Cleveland and Columbus this year, instead of at Columbus alone, as in the past This will be a great accommodation to the 1904 graduating classes of Cincinnati, which are the first classes to be affected by the new law The examinations will be held June 13, 14 and 15

District of Columbia Report—Dr W C Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports that at the examination held at Washington, D C, Jan 14 18, 1904, 80 questions were asked on 17 subjects, and a percentage of 75 was required Of the 11 who were examined, 7 passed, 3 failed and 1 withdrew before the end of the examination The latter graduated from Columbian University in 1903

Moncure J A, A A surgeon Department letter granting leave of absence for thirty days from April 1 1904, amended so that said leave shall be effective from April 10

BOARD CONVENED

Board convened at Stapleton, N Y April 4 1904 for the physical examination of officers of the Revenue Cutter Service Detail for the board P A Surgeon A C Smith chairman, Asst Surgeon T W Salmon recorder

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from April 1 to April 9, 1904:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, March 26-April 2, 1 case.

Illinois: March 26-April 2, Chicago, 5 cases; Danville, 6 cases.

Indiana: South Bend, March 26-April 2, 1 case.

Kentucky: Covington, March 26-April 2, 2 cases.

Louisiana: New Orleans, March 26-April 2, 4 cases, 2 imported.

Maryland: Baltimore, March 26-April 2, 4 cases.

Massachusetts: Lowell, March 26-April 2, 1 case.

Michigan: at 75 localities, March 19-26, present.

Missouri: St. Louis, March 26-April 2, 15 cases.

New York: March 26-April 2, Buffalo, 3; Niagara Falls, 1 case.

Ohio: Cleveland, March 25-April 1, 6 cases, 2 deaths; Dayton, March 26-April 2, 5 cases.

Pennsylvania: Carbondale, March 24-31, 1 case; March 26-April 2, Erie, 2 cases; Philadelphia, 32 cases, 7 deaths; Pittsburg, 4 cases, 3 imported; Reading, March 28-April 4, 1 case.

South Carolina: Charleston, March 26-April 2, 2 cases; Greenville, March 19-26, 2 cases.

Tennessee: Nashville, March 26-April 2, 5 cases.

Virginia: Pocahontas, March 24-31, 6 cases, 2 deaths.

Wisconsin: Milwaukee, March 26-April 2, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, March 6-12, 2 cases.

Belgium: Antwerp, March 12-19, 16 cases, 4 deaths.

Brazil: Rio de Janeiro, Feb. 28-March 6, 45 cases, 3 deaths.

Canada: Quebec, March 12-19, 1 case.

Colombia: Barranquilla, March 7-20, 3 deaths.

Formosa: Jan. 1-31, 9 cases.

France: Paris, March 12-19, 15 cases, 1 death.

Great Britain: March 12-19, Edinburgh, 8 cases, 1 death; Hull, 6 cases; Leith, 1 case; Manchester, 3 cases; Newcastle-on-Tyne, 7 cases; Nottingham, 13 cases; South Shields, 1 case; Glasgow, March 18-25, 46 cases, 4 deaths; Leeds, March 19-26, 2 cases; London, March 12-26, 84 cases; Sheffield, March 6-19, 3 cases.

India: Bombay, March 1-8, 19 deaths; Calcutta, Feb. 20-March 5, 7 deaths; Karachi, Feb. 28-March 6, 16 cases, 2 deaths.

Mexico: City of Mexico, March 13-20, 11 cases, 6 deaths; Vera Cruz, March 19-26, 1 case.

Netherlands: Amsterdam, March 19-26, 3 cases.

Russia: March 5-12, Moscow, 5 cases, 1 death; St. Petersburg, 10 cases, 1 death.

Straits Settlements: Singapore, Feb. 20-27, 1 death.

Turkey: Constantinople, March 13-20, 5 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 28-March 6, 9 cases.

Mexico: Merida, March 13-19, 1 case; Tehuantepec, March 19-26, 3 cases, 1 death.

CHOLERA.

India: Bombay, March 1-8, 1 death; Calcutta, Feb. 20-March 5, 77 deaths; Madras, Feb. 13 March 4, 7 deaths.

Turkey in Asia: Bassorah, Feb. 9-12, 6 cases, 4 deaths.

PLAGUE.

Africa: Port Elizabeth: Feb. 27-March 5, 8 cases, 4 deaths.

Australia: Brisbane, Feb. 6-20, 5 cases: Sydney, March 10, 1 case.

Brazil: Rio de Janeiro, Feb. 28-March 6, 1 case.

India: Bombay, March 1-8, 968 deaths; Calcutta, Feb. 20-March 5, 294 deaths; Karachi, Feb. 28-March 6, 106 cases, 90 deaths; Madras, Feb. 27-March 4, 1 death.

Peru: Lima, March 23-30, 23 cases 4 deaths.

Medical Organization.

Florida.

Citrus County Medical Society.—This society was organized at Inverness, April 4, on the standard plan, with the following officers: Dr. Joseph D. Bennett, Crystal River, president; Dr. James F. Miller, Inverness, vice-president; Dr. Henry O. Snow, Floral City, secretary-treasurer; Drs. R. A. Lowrey, Floral City, Walter E. Armstrong, Crystal River, and Taylor, Crystal River, censors, and Dr. Joseph D. Bennett, Crystal River, delegate to the state association.

Illinois.

Menard County Medical Society.—A society has been organized at Petersburg with the following officers: Dr. Joseph W. Newcomer, Petersburg, president; Dr. Stith T. Hurst, Greenview, vice-president, and Dr. Berton W. Hole, Tallula, secretary.

Louisiana.

Bossier Parish Medical Society.—This society was organized on the standard plan in Shreveport, March 24, with an initial membership of 7, by Dr. Norwood K. Vance, Shreveport, councilor for the Fourth District. Dr. John L. Scales, Alden Bridge, was elected president; Dr. David J. McAnn, Atkins, vice president, and Dr. Clifford H. Irion, Benton, secretary-treasurer.

Avoyelles Parish Medical Society.—Dr. Charles A. Gardiner, Bristol, councilor for the Seventh District, met the physicians of the parish at Bunkie, and assisted in the organization of a medical society on the standard plan, with a charter membership of 19, and the following officers: President, Dr. Cleophas J. Ducote, Cottonport; vice-president, Dr. William G. Branch, Bunkie; secretary, Dr. E. Stanley Matthews, Bunkie; treasurer, Dr. Emil Regard, Mansura, and chairman of committee on scientific work, Dr. David B. Davis, Bunkie.

Mississippi.

Good Work in Mississippi.—Dr. John F. Hunter, secretary of the State Board of Health, is receiving a number of very encouraging reports of the organization of county medical associations in affiliation with the state and national associations. He says that the establishment of these organizations indicates a larger attendance at the annual meeting of the Mississippi Medical Association, to be held in Jackson, April 20, than for many years. Within the past few days six county medical societies have been established and officers chosen for the next year. Closer bonds between members of the medical profession in Mississippi will be established by the launching of these county societies, and the work of the state association greatly facilitated.

Covington County Medical Society.—Physicians of the county met at Collins, March 23, and organized a society with the following officers: Dr. Alexander Fairley, Mount Olive, president; Dr. W. N. Blount, Collins, vice-president, and Dr. Harvey F. Garrison, Seminary, secretary and treasurer.

Newton County Medical Association.—At a special meeting held in Hickory, March 22, at which Dr. J. J. Haralson, Forest, represented the state association, the county association voted to accept the standard plan of reorganization, and chose its president, Dr. G. H. McNeill, Newton, as delegate to the state association.

Clarke-Wayne County Medical Society.—This society was organized at Quitman, March 28, with the following officers: Dr. William H. Boykin, State Line, president; Dr. William J. McNair, Quitman, vice-president, and Dr. J. M. Guthrie, Quitman, secretary and treasurer. Eleven physicians were present at the meeting.

Washington County Medical Society.—This society was organized in Greenville, March 16, with the aid of Dr. Edward H. Martin, Clarksdale, councilor for the First District, with about twenty-five charter members. Dr. Jefferson D. Smythe, Greenville, called the meeting to order, and was made temporary chairman, and Dr. Andrew G. Payne, Greenville, was made temporary secretary. After the adoption of the constitution and by-laws the following officers were elected: President, Dr. Elbert A. Cheek, Arcola; vice-president, Dr. Owen W. Stone, Greenville; Dr. M. O. Shivers, Greenville, secretary and treasurer; Dr. Jefferson D. Smythe, Greenville, delegate to the state association, and Drs. Emmett C. Smythe, Greenville, Owen W. Stone, Greenville, and A. S. Lee, Dudley, censors.

New Mexico.

Chaves County Medical Society.—On March 7 this society was organized at Roswell with 14 members, including all save two of the physicians in the county. The constitution and by-laws for county medical societies prepared by the committee on organization of the American Medical Association was adopted and the following officers were elected: President, Dr. William T. Joyner; vice-president, Dr. John W. Kinsinger; secretary, Dr. William W. Phillips; treasurer, Matthews W. Flournoy, and censors, Drs. Charles M. Mayes, Charles I. Beeson, and T. C. Blackwelden, all of Roswell. The society announces that it is ready to do its part in reorganizing the Territorial Medical Society.

Texas.

A Typical Letter from a Good Councilor.—The following letter to Dr. J. N. McCormack, from a councilor in Texas, is a sample of those that have been received from the councilors in many states:

Greenville, Texas, March 12, 1904.

Dear Dr. McCormack:—. . . I have organized societies in 20 of the 22 counties in my district, taking in Raines County with Hunt. Only two counties remain out, and I will visit both of these this week.

I find nothing in the way of this plan of organization, when it is understood and the work placed in the hands of earnest, enthusiastic men. It has been easy for me to show the profession in my district that it marks an epoch in the history of organized medicine in this country. They are especially pleased with the feature of it which brings membership in the American Medical Association home to the county societies, so that every man's character is passed on by his home people.

I have found no case of strife or individual differences that the parties have not heard me willingly, and which has not yielded readily after mutual explanations. I have given 50 days of my time to this work since I met you at San Antonio. Time after time I have seen physicians meet, discuss and agree to go to work under these plans of organization who had not spoken to each other for years. I have seen the good effect of breaking bread together this year as I have never seen it before.

I shall write to each county secretary in a few days to get a list of the new members since my last visit to them. We will have more than 600 members from my district before the next meeting of the state association. I have visited some of the counties two or three times, have written over 3,000 letters, and yet my expense account for railway fare and everything else has been less than $120. . . . Yours very truly,

C. E. Cantrill, M.D.,
Councilor No. 14, Northern District.

Wisconsin.

Trempeleau and Jackson County Medical Association.—Dr. Wilbur T. Sarles, Sparta, councilor of the Seventh District, recently met the physicians of these two adjoining counties at Galesville, and organized an inter-county association on the standard plan, with the following officers: Dr. George N. Hidershide, Arcadia, president; Dr. William E. Parker, Whitehall, vice-president; Dr. Henri A. Jegi, Galesville, secretary and treasurer, and Drs. George H. Lawrence, Galesville, W. E. McFarland, Trempeleau, and Judson A. Palmer, Arcadia, censors.

Society Proceedings.

COMING MEETINGS.

Medical Association of the State of Alabama, Mobile, April 19.
Medical Society of the State of California, Paso Robles, April 19-21.
Florida Medical Association, Live Oak, April 20.
Medical Association of Georgia, Macon, April 20.
Mississippi State Medical Association, Jackson, April 20.
Texas State Medical Association, Austin, April 26.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 26-28.
Arizona Medical Association, Tucson, April 27-28.
Arkansas Medical Society, Texarkana, May 3-5.
Louisiana State Medical Society, Lafayette, May 3-5.
Nebraska State Medical Society, Omaha, May 3-5.
Kansas Medical Society, Topeka, May 5-7.

CHICAGO LARYNGOLOGICAL AND CHICAGO MEDICAL SOCIETIES.

Joint Meeting held March 9, 1904.

The President, Dr. John Edwin Rhodes, in the chair.

When to Operate and When Not to Operate on the Mastoid Bone.

Dr. Henry Gradle read a paper with this title in which he reviewed the literature, and said that the reports contained therein teach, first, that suppuration of the middle ear, both acute and chronic, involves danger to life. Secondly, that even in the desperate cases reported greater success attends mastoid operations, although many of them must extend into the cranial cavity, and, thirdly, that properly timed surgical intervention would have prevented this serious extension of the disease.

In at least one-third of all instances acute mastoiditis subsides gradually after a climax of three or four days, provided there is free drainage from the middle ear. In chronic cases, a simple opening of the mastoid antrum, although often curative, is generally not the proper operation. In most cases a cure is obtained quicker and with greater certainty by the radical operation, which converts the antrum, the attic and the middle ear proper into one continuous and accessible space with exenteration of contents. A prompt radical operation is the only safe course in all instances in which irritative symptoms indicate active extension of the disease. This immediate indication is given in all chronic instances of otitic suppuration by persistent dizziness, pain or local tenderness, one-sided headache, or any symptoms suspicious of intracranial involvement.

Treatment of the Suppurative Diseases of the Accessory Sinuses of the Nose.

Dr. E. Fletcher Ingals read this paper. He said that in acute cases of suppuration of the antrum the patient should be kept quiet, the pain relieved by hot or cold compresses over the cheek, and the swelling and turgescence relieved by local applications in the region of the ostium maxillare. In chronic cases Christopher Heath recommends entering the antrum above the alveolus through the canine fossa; the tendency to closure being obviated by making an opening a centimeter or more in diameter. The radical operation consists of opening through the canine fossa and curetting thoroughly the lining of the antrum, removing at the same time any dead bone or obstructing septa.

Some cases with suppuration of the ethmoidal cells recover spontaneously, but most of them continue for many months, and even years, unless thoroughly treated. In acute cases relief may frequently be obtained by local medication that will reduce the swelling and thus allow the pent-up secretions to escape. Kiaer and Lapelle, in 364 autopsies on bodies dead from various diseases, found over 13 per cent. affected by suppuration of the sphenoidal sinus, which would indicate that the affection is very generally overlooked. On account of the dependent position of the ostium frontale and the direction of the canalis naso-frontalis, not a few patients affected with acute suppuration of the frontal sinus will recover spontaneously. In others the cure is much facilitated by local remedies which reduce the swelling, such as suprarenalin and cocain, which may be used several times daily, in the same manner as recommended for suppuration of the ethmoidal cells or for closure by swelling of the ostium maxillare, but in a considerable number of these cases the obstruction is due to nasal mucous polypi or to chronic thickening of the middle turbinated body, so that it will not be relieved in this manner. In such cases the polypi should be removed or the anterior end of the middle turbinated cut off, or both.

If the canal is completely closed, and in any case in which the disease does not yield within four or five months to treatment, it is probable that partial septa cause pus pockets in the frontal sinus, or that the walls of the cavity are much diseased. In these conditions a radical operation by an external opening through the anterior wall of the sinus is necessary.

The Symptoms and Diagnosis of the Suppurative Diseases of the Accessory Sinuses of the Nose.

Dr. Norval H. Pierce pointed out those symptoms which are common to suppurative disease of all the accessory sinuses, and followed the lines of description laid down by Hajek. Under local symptoms he discussed headache, neuralgias, secretion, etc. Under general symptoms he referred to fever, congestion and depression, nasal discharge, objective symptoms, and also spoke of atypical hypertrophies of the middle meatus, and dilatation of the maxillary sinus.

In speaking of the diagnosis reference was made to the value of transillumination. The symptoms of disease of the frontal sinus were detailed and its diagnosis discussed; also disease of the ethmoid cells, latent or closed empyema, open empyema, disease of the sphenoidal sinus, and, lastly, attention was directed to only one complication of sphenoidal empyema, namely, the extension of the inflammatory process to the orbit.

Miscellany.

MEXICO AND YELLOW FEVER.

The Yellow Fever Situation on the Mexican Border—What Is Being Done to Protect the United States.

The history of the epidemic of yellow fever which prevailed last fall in Laredo and other towns in southern Texas is detailed in the report of Surgeon G. M. Guiteras, of the Public Health and Marine-Hospital Service. This report shows the efficiency of our Public Health Service, and incidentally adds the weight of its testimony to the now scarcely contestable theory of the transmission of yellow fever solely by the mosquito.

Yellow fever appeared in Tampico, Mexico, in May, 1903, and from this starting point was carried along the line of the Mexican National Railway to Victoria, Linares, Monterey and other towns betwen Tampico and the Rio Grande. The quarantines established by the Mexican sanitary officials were perfunctory and inefficient, and the authorities in these infected Mexican towns persistently denied the existence of yellow fever, thus *creating a sense of false security* which greatly favored the rapid spread of the disease. There is strong evidence to show that the disease was introduced in Nuevo Laredo from Victoria, Mexico, early in August. Inasmuch as the two Laredos are practically one town, and that the Plaza of Nuevo Laredo, Mexico, is a popular resort and is frequented daily by Americans from Laredo, Texas, the infection of the latter town could not have been long delayed.

The first cases in Laredo, Texas, probably appeared in the latter part of July or the first week in August. Laredo physicians, with one or two exceptions, were unacquainted with yellow fever and inclined to be skeptical of its existence. The large peon population of Laredo, made up of the lowest class of Mexicans, ignorant and superstitious, seldom called a physician because of fear of being quarantined or sent to a hospital. Hence these first cases went unrecognized, and, allowing the usual time for the mosquito cycle and period of incubation, the second group of cases, which must have appeared about the third or fourth week of August, also were not recognized, or at least were not reported.

The disease was not officially reported until the third week in September, and when the officers of the Public Health and Marine-Hospital Service, detailed for the suppression of the disease, arrived on the scene, September 25, a very serious condition of affairs confronted them. Cases of yellow fever were reported in rapid succession from widely separated points, this probably being the period of the third mosquito cycle of infection, showing that the disease had already obtained a firm foothold and was widely disseminated among a population almost entirely non-immune. Add to this an abundance of stegomyiæ, thousands of unscreened water tanks and other breeding places, and an entire lack of police or other authority to enforce sanitary measures, and some idea of the difficulties of the situation can be conceived. In addition, there was the extreme difficulty of preventing infected persons crossing from the Mexican side, where the Rio Grande was not only spanned by bridges, but had ferries and innumerable skiffs along its banks, and was also easily fordable at many points. There was always the possibility of infected mosquitoes being blown across the narrow river, as the prevailing winds, before the beginning of the northers, were from the south or southeast.

In spite of these discouraging conditions, the U. S. medical officers set to work, and while the time left before the coming of cold weather was too short to expect, under these conditions, the complete eradication of the disease, some remarkable results were accomplished. These results are best shown by comparing the statistics of the epidemic in the two Laredos—Nuevo Laredo, Mexico, and Laredo, Texas. In Nuevo Laredo, Mexico, where very little anti-mosquito work was done, and that little attempted late in the season, 50 per cent. of the population contracted the disease. In Laredo, Texas, where, after the first of October, fever cases were screened, water tanks and other possible mosquito breeding places were oiled, and infected premises and surrounding abodes disinfected to kill mosquitoes, 1,050 cases developed in a population of over 10,000, constituting only about 10 per cent. of the population.

So thoroughly was the work of destroying mosquitoes, and especially the work of oiling containers and other breeding places performed, that an officer of the Public Health and Marine-Hospital Service, detailed in November to study infected yellow fever mosquitoes, could not find in Laredo, after diligent search, enough stegomyiæ in the adult, larval, or pupal stage to carry on his work.

To prevent a recrudescence of the epidemic of last year, it is necessary to clean up our towns in the vicinity of the danger line, and to induce the Mexicans to do the same in their territory. With these ends in view, the Public Health and Marine-Hospital Service has maintained throughout the winter in the towns on the Texas border an active prophylactic campaign directed toward destruction of mosquitoes and the elimination of breeding places. The surgeon-general also visited the City of Mexico in January and conferrea with the president of the Superior Board of Health of Mexico. As a result of this conference, co-operation in the work of eradicating yellow fever has been promised by the Mexican health officials, and an excellent plan of campaign has been mapped out and inaugurated in the infected Mexican towns by Dr. Liceaga, president of the Superior Board of Health.

The force of medical officers along the Texas border has recently been increased, and these officers are now making house-to-house inspections in Laredo and other towns near enough to the infected territory to be in danger of infection. The city of Laredo has been divided into 30 sections and an inspector is assigned to each of these sections. Under this system daily inspection is possible, cisterns and water tanks are being oiled and covered, and where the residents are too poor to buy the necessary covering, it is furnished at the expense of the United States government. The city authorities of Laredo are actively assisting the officers in minimizing the possibility of a recurrence of the fever, by municipal ordinances which tend to improve sanitary conditions and strengthen sanitary control.

In his instructions to officers engaged in this work, as shown in a recent number of the *Public Health Reports*, the surgeon-general lays particular stress on the necessity of screening at once all cases of fever of whatever origin, and of maintaining this protection until the danger of infecting stegomyiæ is past.

Officers of the Public Health and Marine-Hospital Service have been stationed at Vera Cruz, Tampico, and other Mexican ports, who will keep in touch with local conditions and furnish valuable information to the bureau. The work of oiling and screening water tanks and destroying mosquitoes and their breeding places goes on without remission, and the health authorities of the state of Texas are giving the hearty co-operation and support which are necessary for success. On March 31 Dr. George R. Taber, state health officer of Texas, called a meeting of the health officers of the state at Austin, and resolutions were adopted to report promptly all cases of illness, and to maintain an active anti-mosquito campaign.

The vigilance of the Public Health and Marine-Hospital Service, the evidence of harmony between federal and state officers working for a common result, and the apparent sincerity of the Mexican health authorities in taking proper precautions in their towns, all make for a solution of the problem, and the real prevention of this preventable disease seems to be at least within the bounds of probability.

The Dose of a Trustworthy Drug Is "Enough."—It is often suggested that the physician must not cling too closely to the maximum and minimum dosage statements of the Pharmacopeia. The object of medication in any case is the achievement of some definite physiologic effect. The physician should be able to expect and secure a definite uniform result every time a medicinal agent is used—allowing for the conflict of intercurrent forces or of idiosyncrasy. Drugs or measures that can not be so used are still in the domain of empiricism or experimental medicine. They have their use and their place, but the physician should not add to their number by the misuse of drugs, by using impure preparations or by the administration of a crude drug when the effect desired is the result of one of the active principles that may be isolated. We agree with the editor of the *Alkaloidal Clinic*, who remarks that physicians should deem of greater importance than they do the securing of drugs of definitely known strength and of uniform physiologic results. On such a basis the physician may make deductions from his clinical experiences; without such a basis his path will be beset with discouragements and he will be in danger of the heresy of therapeutic nihilism. With such a drug, a remedy which he can trust to produce a certain effect, a physician should give it boldly until that result is produced.

Remote Results of Ventrofixation.—T. Dolbert analyzes the remote results in 79 cases in which ventrofixation was performed during the last six years at St. Petersburg clinics. (*St. Petersburg. med. Wochenschrift*, Vol. 28, No. 20, 1903.) In 43 it was done on account of retroversio-flexion, and in 36 for prolapse. The patients in the first group were mostly slender young women, generally undernourished, nulliparæ or primiparæ. In 3 the retroflexion was movable; 18 fixed, complicating some affection of the adnexa in 34, the latter being the main indication for operative intervention. The remote results establish that ventrofixation is no more dangerous nor liable to be followed by hernia than any other laparotomy. The uterus remains permanently in its new position. In only one instance did it slip back again, and this was a much enlarged organ which should not have been fastened in this way. The fine objective results were not paralleled by the subjective, as the latter returned in more than a third of all the cases. This indicates that the neurosis apparently attributable to the displacement is in reality more or less independent of it, as is liable in all subjects with a tendency to neurasthenia or hysteria.

The Courage of the Surgeon in Emergencies.—In the *New York Times*, "a Boston physician" speaks thus of General Wood: "I remember an instance in direct proof of what I mean when I say that his successes are mainly due to his magnificent courage, his determination to do what he believes to be right, even in the face of certain punishment. In 1884, then a recent graduate from the Harvard Medical School, he was an interne at one of the Boston hospitals. An interne, I may say in explanation, is required by rule to send for the visiting surgeon in all cases requiring immediate operation, and is himself forbidden to do the work. One day an infant was brought in, suffering from membranous croup. The case was so far advanced that any delay would almost certainly result in death for the little one. Dr. Wood did not hesitate a moment. He began to work at once, carefully, fearlessly, promptly, and successfully. Five minutes later, and while both mother and patient were still in the room, the surgeon, who should have had the case according to rule, walked in. The young physician explained, but would not apologize, as he was asked to do. He had done right, and he was not going to tell any man he was sorry for it, he said. The result was that he was first suspended and then dismissed. And I call that courage."

Military Hygiene.—"The military authorities of India are exceedingly proud of the morale and the hygienic condition of their troops, and the records of the judge advocates and medical departments show a remarkable improvement in these respects, which is largely due to the scientific construction of the barracks, to the enforcement of discipline and regulations framed to suit climatic conditions, a better knowledge of the effect of food and drink, and the close observance of the laws of hygiene. The climate is very severe, particularly on Europeans, who must take good care of themselves or suffer the consequences. The death rate in all armies in time of peace should be much lower than in the ordinary community, because recruits are required to submit to physical examinations, and none but able-bodied men are enlisted. The death rate in the army of the United States before our soldiers were sent to the Philippines was remarkably low, only three or four per 1,000 per year. Some years ago in the army in India the mortality from disease was as high as sixty-nine per 1,000, but by the introduction of the reforms mentioned the rate had been reduced to nineteen per 1,000 in 1880, and for the last ten years has been less than sixteen per 1,000." The above, from the *Chicago Record Herald*, is in contrast to the reports about the French army. It is said that during 1903 50,000 cases of sickness occurred in the barracks of the French army. There were 3,500 deaths and 19,000 men were discharged because of physical disabilities. This very high rate is said to be due to the unsatisfactory state of the barracks in which the men live. According to the medical reports, only a very small part of the barracks had a proper allowance of air. Tuberculosis and typhoid are increasing with alarming rapidity. It is a noteworthy fact that the French army has only 1,500 physicians while the German army has 3,000.

Outbreaks of Sore Throat Due to Milk from Diseased Udders.—In England there have recently occurred outbreaks of sore throat due to milk obtained from cows with diseased udders. In an outbreak which occurred in Surrey the patients suffered from severe sore throat, with constitutional symptoms and enlargement of the cervical glands, which sometimes suppurated. The cases varied in severity. Ulcerated sore throat, follicular tonsillitis, and quinsy occurred. In several cases the cervical glands were markedly enlarged and they sometimes suppurated. In some cases after a few days pains in the joints occurred, which were possibly due to spread of the infection. Unlike an epidemic of diphtheria adults suffered in greater numbers than children. It was found that four of the cows in a herd which supplied the milk taken by the patients were suffering from mammitis and yielded pinkish-colored curdy milk, which in the case of two formed a layer resembling pus. Bacteriologic examination showed the presence of organisms—streptococci and staphylococci—similar to those usually associated with severe cases of sore throat and similar to those found in swabs taken from the throats of the patients. A noteworthy point was that external examination of the udders gave no indications of the condition such as would have been yielded by tuberculous udders. It was only on milking the cows that the mammitis was discovered. In another outbreak of sore throat which took place at Finchley, a London suburb, very similar symptoms were observed. About 100 cases occurred. After an incubation period of about 24 hours the patients complained of sore throat, malaise and enlargement and tenderness of the cervical glands. The tonsils were frequently inflamed and sometimes suppurated. In some cases the posterior cervical and supraclavicular glands were enlarged. The complications were gland abscesses, cellulitis, and neuralgia. In a few cases a measly eruption was observed on the lower limbs. Two of the cows which supplied the milk were found to have contracted a chill, with the effect that their milk was curdled. It is suggested that the only way to prevent such outbreaks is regular and frequent veterinary inspection of milch cows.

The Small Medical Society.—The size of a medical society may indicate somewhat its strength and importance. From the standpoint of the society, growth is a good sign. The more members brought to join it, the wider its influence, the larger the number benefited by it. But from the standpoint of the individual member who goes into a medical society to learn something, or for the opportunity of seeing things from other men's points of view, the benefit is not at all proportioned to the size of the society. What any one of us can hear, does not depend on how many others are listening to the same speaker. What one can understand or what new ideas will be awakened in him, depends but little on how many others are present. In any well-conducted meeting, there can be but a single speaker at a time. For the purpose of the member who is learning anything, one speaker and one hearer constitute the active participants, even in the largest gatherings. In many respects the ideal conditions for learning exist only when there are but two present. So that there can be question and immediate answer, and the speaker's words can be addressed exactly to the thought of that particular hearer. One might wonder why any one should prefer to listen in a large medical gathering rather than in a small one. Of course, if one goes to a medical meeting solely for the benevolent purpose of instructing his fellow-members, or for the less benevolent purpose of advertising his skill in some specialty, or to hear himself talk, or to get his name in the papers, the larger the meeting he can get to listen to him the better. But the mass of those who go to medical meetings are listeners. Even of those who talk, fewer can do so in the larger meetings. This has led to the breaking up of the largest medical gatherings into "sections," and always with increased interest and benefit. In view of these facts there should be no hesitation about organizing a county medical society because its membership would be small. When physicians will not do so, or will not attend their county medical society because its meetings are small, they do not understand the value of contact with others of their profession. They do not realize that modern medicine has been built up by the contact of one mind with another. A vital difference between the physician and the quack is that one recognizes the importance of working with his fellows, while the other does not.—Edward Jackson in *Colorado Medicine*.

The anti-malarial operations in India, at Mian Mir, which were initiated by the members of the Royal Society's Malarial Commission to demonstrate that malarial fever can be prevented by destruction of the particular mosquito which is the definite host of the parasite, have been partly successful. Mian Mir was chosen as a very malarious station, and as one in which a marked reduction in the number of mosquitoes could be affected. The season of new infection begins in July, and the number of new infections increase until October, when the maximum is attained. The *Anopheles culicifacies* is the chief, if not the only carrier of malaria. It breeds in the irrigation watercourses, which run more or less throughout the year. Only two forms of malarial parasite have been found—the benign tertian and the malignant tertian. A high percentage of children in the various bazaars are infected, and as they are not treated, form the chief source from which anopheles become infected. The prevalence of malaria is greatest near the breeding place. In April, 1902, operations were commenced. They consisted of destruction of the anopheles, removal of a number of infected persons from the breeding places, destruction of the parasites in infected persons by quinin, and administration of prophylactic doses of quinin to the troops. The operations against the mosquitoes were principally directed against the larvæ. They consisted in keeping the sides of the watercourses smooth and free from grass for many months, in lining one of the watercourses with brick and plastering it with cement, in drying out and cleansing each branch watercourse every ten days, and in pouring kerosene oil on the watercourses, and in filling in pools and emptying out water from the surface drains. Bricking in of the old watercourses was not successful in destroying the breeding grounds. To achieve this a very narrow channel had to be built in the bed of the old one to secure a swift running stream. In the hot season the oiling of pools had to be repeated at least every three days as the larvæ developed rapidly and the oil quickly evaporated. The *Anopheles culicifacies* appears to survive the Punjab winter solely by "hibernating larvæ." It was attempted during the winter to kill all such larvæ within a wide area. By the end of February, 1903, all larvæ had been killed within a radius of two miles, and no adult insects were present in the houses. Nevertheless, the number of adults present in the houses and the number of larvæ in the breeding places increased month by month to a maximum in October, and then quickly decreased, although operations were discontinued. It seems doubtful whether anything short of permanent extermination of all breeding places will produce a marked reduction. However, these experiments, which were carried out in the bazaars and military lines, prove that even a slight reduction affects the amount of malaria. The number of cases of malarial fever among the troops was the lowest on record.

Physical Culture.

Jay W. Seaver, M.D., of Yale University, president of the Chautauqua School of Physical Education and of the American Institute of Physical Culture, spoke before the physicians of Boston and vicinity, at the rooms of the institute, March 12. Dr. Seaver referred to exercise as being as necessary for health as sunlight, fresh air, and food; no healthy animal grows into vigorous maturity without performing many movements that are in themselves useless and unnecessary so far as accomplishing work is concerned; but the movements are taken from an innate restlessness that makes the young child play instead of rest. All play is founded on physical activity, and this activity becomes recreative, restful and helpful, according to the needs of the body.

Exercise is a therapeutic means that can not be ignored. For years attention has been given to what has been called medical gymnastics in the treatment of various forms of disease, and the method has gradually grown in the estimation of medical men until it is the chief agent used in treating many cases of deformity, malnutrition and nervous conditions.

Exercise may be looked upon from the esthetic standpoint, as a means of producing a more symmetrical and artistic physical development, but more especially in producing a graceful carriage and a control of the body. Emphasis, however, was laid on exercise as a developmental and therapeutic measure, a means of securing such strength and activity as is characteristic of health and ability to do the work of life. This is accomplished largely through the influence that exercise has on the nervous system, in giving it a normal outlet for the force that is generated in the brain; as it were, putting an implement in the hands of the brain for the accomplishing of its purpose; and, in the second place, it improves the circulation, so that each part of the body has its due amount of nutrition, and its waste material is swept away, so that the tissues are not poisoned by the products of ordinary wear and tear.

The problem of nutrition to-day is not so largely a matter of abundance of food as it is an economic use of food by the system, and this economy is carried out by adequate circulation that eliminates waste and overcomes local stagnation. Modern life has its decided tendency to limit the physical activities, and many of the ills that require the attention of physicians are due to the physical restraints that encumber life. The modern business man does not get his morning walk to his place of business, his communications with other business men are carried on over the telephone, and the brain in general attends to a multitude of details that in previous generations would have been mixed in with a large number of physical activities that would have reacted favorably on his general nutrition.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Empyroform.

Skarlek, *in Amer. Med.*, recommends empyroform in the treatment of eczema to calm the itching and check the secretion. It can be used where tar can not be tolerated by the patient.

It may be combined as follows:

℞. Empyroform
Amyli, āā ....ʒvi 24
Vaselini ....℥iss 45
M. Ft. unguentum. Sig.: Apply locally; or:

℞. Empyroform ....ʒiv 15
Glycerini ....ʒiiss 10
Aq. destil. ....℥i 30
Alcoholis ....ʒiiss 10
M. For external use; or:

℞. Empyroform ....ʒi-ʒiiss 4.-10
Spts. chloroformi
Tinct. benzoini, āā............................℥ii 60
M. Sig.: To be applied locally to the affected areas.

Dysmenorrhea.

The following combination is recommended to relieve the pain in dysmenorrhea:

℞. Dionin ....gr. xv 1
Aq. laurocerasi............................℥i 30
M. Sig.: Thirty drops in water three or four times daily.

Tapeworm.

The following outline of treatment is recommended by C. Query in the treatment for the removal of tapeworm:

℞. Pepo (seeds) ....ʒx 40
Ext. granati ....ʒiiss 10
M. Sig.: Divide into twenty parts and take five every half hour, after fasting for twenty-four hours. One-half hour after the last dose the following should be given:

℞. Tinct. jalapæ co.
Syr. frangulæ, āā............................ʒvi 24
M. Sig.: At one dose.

Rheumatism in Children.

The diet and the digestive organs must be carefully observed in the treatment of rheumatic conditions in children. according to J. E. Winters in *Med. Rec.*. Calomel should be given, followed by rhubarb and soda. The latter should be continued as long as the tongue is furred. The dose of the rhubarb should vary with the condition of the bowels. Soda should be given in twenty-grain doses before each meal. Milk should be the sole food as long as evident symptoms remain. The proteid of the milk contains no nuclein, and yields no uric acid. It does contain potassium phosphate and citric acid.

Cereals must be eaten without sugar.

Sweets and animal broths, alcohol and sweets in adults are the bane of rheumatic patients.

Vegetable soups—pea, asparagus, celery, potato, bean, or tomato—are very nutritive. Animal broths or cereals are valuable, as adjuncts, to stimulate the appetite, and not for their food value. As soon as the symptoms of rheumatism have vanished, strained cereals, vegetable soups, baked potato, bread, green vegetables and fruit may be added to the diet. The failure in the dietetic management lies in the excessive use of broths and other animal food, sugar and sweet desserts, the use of alcohol, and the withdrawal of fruits and cereals.

Thrush.

Thrush, according to Illoway in *Med. News*, is a disease of filth and uncleanliness on the part of the mother or nurse, and is contracted through the bottle, breast or nipple, and the parasite is always introduced from without. In the lighter forms of thrush, where the epithelial layer has not been penetrated, sodium borate made up with honey into a paste and applied locally, is of value. The hyposulphite of soda is recommended by the author, on the basis that the parasite thrives only in an acid medium, as asserted by some authors. He combines it as follows:

℞.	Sodii hyposulph.	gr. xx	1	30
	Aq. destil.	ʒv	20	
	Glycerini	ʒiii	12	

M. Sig.: One teaspoonful every two hours, to be taken internally. And it should be applied locally with a camel's hair brush.

In the severer forms silver nitrate is recommended by some authors.

The following combination is also recommended as of great value as an antiseptic and astringent:

℞.	Zinci sulph.	gr. ii-v		12-.30
	Aquæ rosæ	ʒii	60	

M. Sig.: Apply locally.

A weak solution of the bichlorid of mercury in alcohol and applied with the finger is said to effect a cure after one or two applications. This, however, should be applied only by the physician.

Baginsky recommends the application of potassium permanganate topically in a 1 to 25 solution, and resorcin internally in solution of 1 to 100; one to four teaspoonfuls being given daily. The author places the greatest faith in the application of iodin combined as follows:

℞.	Tinct. iodi	ʒss	2	
	Glycerini	ʒiiiss	14	

M. Sig.: Apply locally with a camel's hair brush pencil.

By this latter treatment the author states that the disease is completely eradicated within three or four days after the first treatment. He does not ascribe all the curative properties to the iodin, but regards glycerin as a very important factor. This treatment surpasses any treatment heretofore instituted; it is harmless and rapid in its action.

In cases where aphthæ occur in the mouths of adults the following combinations are of service:

℞.	Formalin	m. viii		50
	Aq. camphoræ	℥iii	90	

M. Sig.: As a mouth wash; or:

℞.	Pot. chloratis	ʒss	2	
	Tinct. myrrhæ	m. xx	1	30
	Elix. calisayæ q. s. ad	℥iii	90	

M. Sig.: One teaspoonful in water every three hours.

Or as a local application:

℞.	Acidi salicylici	gr. x		65
	Acidi borici	ʒss	2	
	Glycerini	ʒii	8	
	Aquæ q. s. ad	℥ii	60	

M. Sig.: To be applied locally to the ulcers.

Anal Fissure.

Katzenstein, in *Merck's Archives*, gives the following outline of treatment in fissure of the anus: Anesthetize the nerve ends in the fissure by applying cocain and overcoming the spasmodic contraction of the sphincter with belladonna and disinfecting the parts by applying ichthyol, combined and applied as follows:

A piece of cotton is twisted into a cord about the size of a knitting needle and dipped into a solution composed of:

℞.	Ext. belladonnæ	gr. viii		50
	Cocainæ hydrochlor.	gr. i		06
	Ichthyol	ʒiss	6	

M. Sig.: Insert the cotton in the rectum along the wall opposite the fissure, where it is left until expelled spontaneously. According to the author this application repeated twice a day will effect a cure within a week or two weeks.

Local Medication in Diseases of the Throat and Nose.

The following combinations are recommended by Ball in his "Dis. of Nose and Pharynx," as local antiseptic applications in the treatment of throat and nasal troubles:

℞.	Acidi carbol.	gr. iv		25
	Aquæ calcis	℥i	30	

M. Sig.: As an antiseptic gargle in diphtheritic sore throat; or:

℞.	Liq. hydrarg. perchlor.			
	Glycerini, āā	ʒi	4	
	Aquæ q. s. ad	℥i	30	

M. Sig.: As an antiseptic gargle; or:

℞.	Liq. potass. perman.	m. ii		12
	Aquæ	℥i	30	

M. Ft. solutio. Sig.: To be used locally in the form of a gargle.

The following combination containing tannin may be used locally as a spray or gargle:

℞.	Acidi tannici	gr. x-xx	.65-1	20
	Glycerini	ʒss-i	2.-4	
	Aquæ	℥i	30	

M. Sig.: As a spray or gargle, or combined as follows:

℞.	Aluminis	gr. viii		50
	Acidi tannici	gr. vi		40
	Aquæ q. s. ad	℥i	30	

M. Sig.: As a local application.

In inflammatory, ulcerative and diphtheritic sore throats the following combination is recommended by the author:

℞.	Tinct. iodi	gtt. iiss		15
	Sodii chloridi	gr. v		30
	Aquæ	℥i	30	

M. Sig.: As a gargle, to be repeated several times through the day.

In chronic pharyngitis the following is recommended:

℞.	Iodi	gr. x		65
	Potass. iodidi	gr. xx	1	30
	Glycerini	℥i	30	

M. Sig.: To be applied locally on a swab.

About three minims of the oil of peppermint may be added to the foregoing if an anesthetic effect on the mucous membrane is desired.

In the treatment of ozena the following is recommended:

℞.	Thymol	gr. ss-i		03-.06
	Spts. vini rect.			
	Glycerini, āā	ʒss	2	
	Aquæ q. s. ad	℥i	30	

M. Sig.: To be used as a stimulating spray.

As an insufflation to be used in chronic rhinitis and nasopharyngitis the following is of service:

℞.	Acidi tannici	gr. x		65
	Pulv. camphoræ	ʒi	4	
	Pulv. amyli q. s. ad	℥i	30	

M. Sig.: To be insufflated two or three times daily.

A stimulating powder, recommended in atrophic rhinitis and some of the forms of chronic rhinitis, may be composed as follows:

℞.	Acidi salicylici	ʒi	4	
	Magnesiæ ponderosæ	℥i	30	

M. Sig.: To be used in the form of an insufflation.

Quinin Subcutaneously.

The following combination containing quinin is recommended by Aufrecht, administered hypodermically:

R.	Quin. hydrochlor.	gr. viiss	50
	Urethani	gr. iv	25
	Aquæ destil.	ʒi	4

M. Sig.: At one dose hypodermically.

The urethane, according to the author, increases the solubility of the quinin and consequently lessens the *quantity of fluid necessary to hold the quinin in solution.*

[Urethane is an ethyl ether of carbamic acid obtained by heating a salt of urea with ethyl alcohol.]

Erosions of Cervix Uteri.

According to an abstract in the *N. Y. and Phil. Med. Jour., Lutaud recommends the following combination as a local application in the treatment* of simple erosions of the cervix accompanied by slight inflammatory changes:

R.	Tinct. iodi	℥ss	15
	Morph. hydrochlor.	gr. x	65

M. Sig.: Apply to the cervix with a small brush every *second day, tamponing in the meantime* with cotton.

Small ulcers may be touched with a stick of silver nitrate. If large or chronic and co-existing with *endometritis and* leucorrhea, the following powder should be applied locally:

R.	Iodoformi	ʒx	40
	Acidi salicylici		
	Bismuthi subnit., āā	ʒiiss	10
	Camphoræ	gr. lxxv	5

M. Sig.: Apply with an insufflator, followed by *a tampon.* The camphor is used to mask the odor of the *iodoform.*

If gonorrhea is suspected, wash the surface of the ulcer with hot water and apply the following:

R.	*Fuchsin*	ʒiiss	10
	Alcoholis		
	Aquæ, āā	℥ii	60

M. To be painted over the ulcers.

A tampon should be subsequently inserted, consisting of iodoform gauze and permitted to remain for twenty-four hours. If a fetid discharge appears, inject potassium permanganate 1 to 5,000 solution.

Medicolegal.

Not Evidence of Insanity.—The Supreme Court of Idaho holds, in the case of Curtis vs. Kirkpatrick, that the fact that one is a believer in spiritualism, and makes many statements apparently unreasonable, is not evidence of insanity.

Act as to Manufacture of Clothing Valid as Health Law.—The Court of Appeals of Maryland, in the case of State vs. Hyman, holds constitutional, as a health measure, the legislation of 1902 regulating the manufacture in tenement and dwelling houses of wearing apparel intended for sale. It says it supposes that it is a matter of fact of which a court may take judicial notice that the manufacture of wearing apparel in improperly ventilated, unsanitary and overcrowded apartments will likely promote the spread of, if it *does not* engender, disease, and it is obviously within the police power of the state to regulate the number of persons who may be employed in any tenement or other establishment where this manufacture is carried on, so that the public health may be conserved. Again, referring to a statutory provision that at least 400 cubic feet of clear space should be allowed in each room for each occupant in manufacturing establishments, and that a permit be secured setting forth the number of persons allowed to be employed in each room, the court says that it certainly requires no discussion to show that such a regulation is strictly and essentially *a* health regulation.

Trial Too Soon After Surgical Operation.—The Supreme Court of New Jersey says that, in the personal injury case of Searles vs. the Elizabeth, Plainfield & Central Jersey Railway Co., the company sought *a new trial on the* ground of excessive damages. If the disability resulting from the injuries was likely *to* be permanent, the damages would not be regarded *as* so excessive as to warrant an interference with *the* verdict, which awarded to the wife $12,000 damages, and to the husband $3,000, for injuries to the former, who sustained severe bruises of the head, limbs and spinal column. But it appearing that the *trial was* brought on so soon after a surgical operation on the patient, namely, a couple of days *over a* month after the removal by an incision of the coccyx, that sufficient time had not elapsed to enable the physicians to determine as to whether the operation would result in her complete or partial recovery—a result which they regarded, however, as highly *probable*—and it thereby appearing that justice *had not* been done by the verdict, it was held that, in the exercise *of* its sound discretion, it became the duty of the reviewing court to set aside the verdict and grant a new trial.

Death from Poison Taken for Coercion or in Experiment.—The Supreme Court of Michigan says of the case of Courtemanche vs. Supreme Court of the Independent Order of Foresters that it was a peculiar one. Perhaps none could arise where the act of the deceased (if the defendant's *claim* was true that his death was due to the voluntary taking of carbolic acid, not with the intent of causing death, but to frighten his wife into giving him money) could present a more pusillanimous act. But it holds that such act would not prevent a recovery of benefit insurance by the widow, though the certificate stated that it did not include assurance against self-destruction or suicide. Perhaps, it says, the word "culpability" is a proper one to use if not enlarged to include negligence, in which no moral question is involved, but it thinks such a question would be more appropriately raised under a provision excepting cases of death caused while engaged in an unlawful act—a provision found in most policies, and regarding which the authorities *are numerous.* It was urged that a policy which in express terms should contemplate and provide insurance against the danger resulting from the voluntary taking a chance of death, as in this case, would be void, as opposed to public policy. The court answers that, if the proofs showed that this was an experiment to determine whether death would follow *the taking of the drug,* showing that *the contingency* of death was not overlooked, *it* is possible that it might be justified in saying that such act, if followed by death, was not within the intent of the parties to the contract; but there was nothing in this case to indicate a design to take life, or that deceased thought that he was courting danger of death.

Dying Declarations Not Altered by Call for Relief.—In Hawkins vs. State, where the Court of Appeals of Maryland affirms a conviction of manslaughter by an abortion, an exception was taken to the admission of certain declarations on account of the testimony of a physician that when he was called in the declarant said: "Oh, doctor, I am dying. I want you to relieve me." It was argued that this was rather a cry for help than the utterance of an abandonment of *hope.* Again, it was said that she continued to repeat she was dying, and that he must help her—must relieve her in some way. But the court says that to assume, in the face of all testimony in the case, that her cry for relief disproved the sincerity of her statement that she knew she was dying, would be to deny to her the privilege of asking the alleviation of what *the* doctor said he knew as soon as he saw her was intense *agony.* Nor, the court continues, was it a natural or reasonable conclusion that the doctor did not think death impending because he gave her a hypodermic injection, and told her she would be relieved in a little while. This injection was plainly given to relieve the agony, and it is common knowledge that such treatment does mercifully render suffering or dying persons insensible to pain. The relief the doctor promised *was* what she asked—a respite from agony, not an escape from death. And it must not be forgotten that it is not material the physician may think the patient may or will recover if the latter fully believes death is actually impending. The court says further that it can not adopt the view of the Kentucky court in Matherly vs. Commonwealth, 19 S. W. Rep. 977, that the desire to have a physician sent for clearly indicates in any case that the deceased had hope of living, though he said he was going to die. This inference must be controlled by all the circumstances of the case.

April 2.

1 *Fifteen Years' Experience with Uterine Fibroids. Willis E. Ford.
2 *Electricity in Medicine. James J. Walsh.
3 Preliminary Report of a Series of Metabolism Observations Made in Atrophic Arthritis, Hypertrophic Arthritis, Osteitis Deformans and the Normal. (To be concluded.) Joel E. Goldthwait, Charles F. Painter and Robert B. Osgood.
4 *Sarcoma of the Nasal Passages. An Inductive Study Based on the Records of 150 Cases. J. A. Watson.
5 Toxemia Associated with Tuberculosis of the Cervical Lymphatic Glands, with Report of a Case. Arthur W. Elting.
6 Acquired Hydrophthalmus. Edward Stieren.
7 Use and Abuse of the Imagination in the Experiments and Observations in Medicine. John C. Hemmeter.

1. **Uterine Fibroids.**—Commencing with the history of the surgery of fibroids, Ford relates his own experience. The total number of cases he has treated and of which he has been able to ascertain the subsequent histories has been 162. Of this number 96 were treated by galvanism; 26 were improved as regards hemorrhages; pain, etc., and 7 recovered. Some few of the above improved relapsed. Twenty-five patients were improved, that is, the tumor became smaller, and in only one case was there any accident or injury from the use of the heavy current of electricity. Of the 31 cases treated by tying the uterine arteries through the vagina and by curettement, together with medicinal treatment by ergot, thyroid, etc., 24 were temporarily improved and 7 unimproved, though in the improved cases the tumors were not appreciably diminished in size. He thinks the method of tying the arteries is not advisable. The number of cases operated on was 61. Six of these were by abdominal section and external treatment of the stump; 2 died. In one case the patient died from cerebral apoplexy, which she had suffered from previously, the other had a very large tumor, the fibroid sloughed and death was due to septicemia. Since then all his abdominal operations have been done by supravaginal amputation after Baer's method, with 4 deaths in 34 operations. By vaginal hysterectomy he has removed 10 with one death. The number of operations was rather larger than would be the case ordinarily, and he thinks there are many cases in which operation is not called for, and quotes Hirst in respect to the indications for operation. He thinks that fibroids have a definite period of growth, though not according to any well-understood rule. In many cases they disappear. His rule now is to operate and remove any fibroid that is threatening life by hemorrhage, any soft, rapidly-growing myomas, any very large tumor causing pressure on the adjacent organs so as to produce invalidism, and any tumor which seems to be undergoing degenerative change. Many small fibroids have remained stationary under his observation for 15 years. A few tumors have disappeared without his knowing the cause. While no treatment other than surgical is of much service, if it is declined then galvanism will do more than any other method.

2. **Electricity in Medicine.**—Walsh apparently thinks that electricity is over-estimated, and that much of its effect is due to mental suggestion, yet there are certain results, such as an increase of blood pressure from static electricity, which may produce great improvement, and the relief of neuralgia by the Roentgen ray treatment, etc. He believes that we are only on the threshold of our knowledge in regard to radioactivity. It may yet bring us physical remedies as powerful as the chemical substances which we have used empirically.

4. **Sarcoma of the Nasal Passages.**—Watson finds from an analysis of 150 cases, so far as it goes, that there seems to be a greater liability to nasal sarcoma in the fifth decade than at other periods. Otherwise age seems to have little effect. Males are much more commonly affected than females. He thinks that it is not at all improbable that sarcoma arises from malignant transformation of nasal polypi, and gives his arguments for this view. Stenosis is necessarily the most common symptom. Spontaneous hemorrhage is next. Pain is mentioned but twenty-four times in the records of the series, though he thinks it is much more frequent than this. When it occurs it may vary in type and location. Commonly it is referred directly to the growth, but is sometimes widely radiated. Offensive discharge and external deformity add to the inconveniences. Serious impairment of the general health is often postponed until late. He discusses the diagnosis, and remarks that it is probable that sarcoma of this region is less malignant than that occurring elsewhere. The occurrence of metastasis is extremely rare; he has found it mentioned but three times. The average duration of life in the fatal cases appears to be about two years from the first appearance of the symptoms. Outside of surgery the only hopeful treatment is that by toxins, either of *Streptococcus erysipelatis* or Coley's fluid. He is convinced that the restriction of the growth in his own third case was due to the attacks of erysipelas. In 64 cases treated by intranasal operation, the percentage of recoveries was 54.68, and he thinks that this proportion indicates the propriety of the adoption of the milder operative measures in selected instances, at least. There is little justification, he holds, in the objection on account of the possibility of exciting the growth to greater malignancy. In any event there can certainly be no justification for primary external operation on small pedunculated sarcoma in an easily accessible region.

Medical Record, New York.

April 2.

8 *Hip and Thigh Amputations for Sarcoma of the Femur. George F. Shrady.
9 *Diagnosis of Thoracic Aneurism. Charles E. Nammack.
10 *Modern Treatment of Dacryocystitis. Alfred Wiener.
11 *Thymic Tracheostenosis with Report of a Fatal Case. William W. Carter.
12 The Kollmann Five-glass Test. George T. Mundorff.
13 Antistreptococcic Serum in the Treatment of Smallpox. Alfred C. Smith.
14 Importance of Treatment in the Early Stages of Arterial Degeneration. Louis F. Bishop.
15 Five Laparotomies on One Patient. Howard Crutcher.
16 Our Rural Water Supplies. A Word for the Thoughtful. Harvey B. Bashore.
17 A Radiographic Surprise. W. I. LeFevre.

8. **Sarcoma of the Femur.**—Shrady reports a case of amputation for sarcoma of the femur which, on account of the patient's objections, was not performed at the hip-joint, but as near to that point as was safe without sacrificing the joint. The patient has remained well for over twenty-one years. He remarks from this case and from other facts that, considering the small number of recoveries altogether, this speaks well for the possibility of suspending the extreme operation in some selected cases. There are few objections, he says, to thigh amputation, which do not apply to complete removal of the femur, and while he does not oppose hip disarticulation for sarcoma on general principles, he is still inclined to think that in some cases simple thigh operations may succeed, as in the case reported.

9. **Thoracic Aneurism.**—Nammack describes the symptoms of thoracic aneurism and remarks that while sometimes the diagnosis is easy, in other cases it may be exceedingly indefinite and obscure. It is determined by the recognition of the causative conditions, the symptoms and physical examination, not assuming the existence of aneurism in the absence of expansile pulsation. Aneurism of the ascending aorta gives better physical signs than that of the descending portion. Aspiration may be required in some cases. The value of the *x*-ray in diagnosis is considerable. The condition, he thinks, is not as rare as has been considered in the past. He enumerates other thoracic conditions which may give rise to confusion, such as solid intrathoracic growths, carcinoma, mediastinal abscess or tumor and pulsating empyema. Other conditions such as aortic regurgitation with dilatation of arch, aortic stenosis, and cardiac hypertrophy may be differentiated by careful reading of the physical signs. It is a mistaken notion in clinical medicine that aneurism will furnish an invariable thrill and mur-

mur. While the prognosis is bad, cure may occur from obliteration of the sac by coagulation of the blood, and the aim of treatment is to secure this by retarding the circulation and lowering the blood pressure. Absolute rest in bed, restriction of food and drink and the use of iodids in fair but not large doses will accomplish all that can be done.

10. **Dacrocystitis.**—Wiener pleads for more radical operation in this condition—extirpation of the sac. He thinks the aftereffects have everything in favor of extirpation and nothing against it: it has the advantage of destroying the source of infection and is in experienced hands a simple procedure. The indications are long-continued suppuration, chronic blenorrhea of the sac, chronic catarrh of the sac, with an organic stricture, disease of the bone with caries, and blennorrhea, and in relatively recent cases, with ulcus serpens or when an operation for cataract or glaucoma is contemplated or in fresh injuries of the cornea and in tuberculosis of the sac. He thinks this operation is growing in favor among continental surgeons.

11. **Thymic Tracheostenosis.**—This term is used as differentiating the condition caused by pressure of a hypertrophied thymus on the trachea, from an enlargement of the gland downward, interfering with the circulation. Carter reports a case which leads him to make the following observations and suggestions:

1. In all cases of laryngeal stridor it should be determined whether or not the thymus is enlarged.
2. On account of surgical shock being badly borne by infants, and especially those in this condition, if the symptoms are not urgent, postural treatment should be tried, and if, in any position of the head and neck, relief is afforded, that position should be maintained by suitable apparatus until Nature has effected a cure by enlargement of the thorax, strengthening the tracheal rings, and diminution in the size of the gland.
3. Intubation, tracheotomy and artificial respiration do no good.
4. The surgical procedure of opening the mediastinum, bringing forward the gland and stitching it to the tissue over the sternum, should be performed immediately if there is danger from asphyxia.

Medical News, New York.

18 *Specific Therapy of Tuberculosis and Vaccination Against the Disease. Eduardo Maragliano.
19 *Treatment of Neurasthenia. Howell T. Pershing.
20 Abdominal Ascites with 150 Tappings. E. K. Browd.
21 *Home Treatment of the Tuberculous "Is Just As Good"--But It Is Not. Henry Levien.
22 *Importance of Dropsy as a Symptom. A. C. Morgan.

18. **Tuberculosis.**—This article is noticed editorially and in the news department last week.

19.—This article appeared elsewhere. See The Journal of February 20, ¶39, p. 558.

21. **Tuberculosis.**—Levien criticizes the home treatment of tuberculosis, which he thinks fails through lack of proper hygienic control, the indulgence of friends and the want of facilities to meet the conditions. He reports two cases, which he thinks illustrate its failure. It is our duty, he says, to have the public impressed with the importance of fresh air, nourishing food, and above all of rigid supervision by physicians and nurses. These needs are best met by establishing sanatoria in sufficient number to supply the demands. The home treatment as a treatment is meaningless and a step backward, and may prove a menace to consumptives and mislead the public mind in believing it to be a new treatment.

22. **Dropsy.**—Morgan points out the importance of dropsy as a symptom, the cause of which, he thinks, must always be sought for and removed.

New York Medical Journal.

April 2.

23 *Critical Review of Some of the Recent Literature of Tuberculosis. Jonathan Wright.
24 *When Should the Tuberculous Patient Be Sent from Home? C. P. Ambler.
25 Laboratory Diagnosis. (To be continued.) M. P. Overholser.
26 Skiagraphic Errors; Their Causes, Dangers and Prevention. (Continued.) Lewis G. Cole.
27 Case of Infection with the Bacillus Aerogenes Capsulatus. S. W. Sappington.
28 Some Drug and Alcoholic Habitués. Samuel B. Lyon.

23. **Tuberculosis.**—Wright's paper is largely a review of Behring's theories, which are criticised in some detail. He thinks that Behring minimizes heredity too much, and that the majority of patients with phthisis will be found to have phthisical ancestors.

24. **Tuberculosis.**—Ambler discusses the climatic and sanatorium treatment of tuberculosis. He thinks the congregation of a number of patients in a sanatorium or carefully conducted boarding-house is preferable to allowing them to go to houses where hygienic regulations are not sufficiently considered. The advantages of change of climate may be summed up in better nutrition. The patient should endeavor to remain in the region where the improvement has occurred, and months should elapse after all signs of the disease have subsided before he returns to his own home.

Boston Medical and Surgical Journal.

March 17.

29 *Forcible Correction in Lateral Curvature of the Spine. Fourth paper. Robert W. Lovett.
30 *Hydrotherapeutic Prescriptions. Joseph H. Pratt.
31 An Account of the Work, Including Obstetrical Technic, at the Lying-in Hospital of the City of New York. Charles H. Bradley.

29. **Lateral Curvature of the Spine.**—Lovett criticises the methods that have been adopted, showing their disadvantages, and claims that the best chance for improvement in cases of severe scoliosis seems to be first, in the use of severe force to secure an improved and, if possible, over-corrected position temporarily and, second, to retain as much as possible the position thus secured during some part of the growing period. For this purpose a high degree of force is required. He deals with the subject theoretically, and describes the apparatus which has been constructed by Dr. E. B. Adams of the Boston City Hospital. It consists of a strong oblong frame fitted with a movable cross-bar, holding clamps for the pelvis, and a series of three rings, likewise movable, at the poles of which are inserted screws by which great pressure can be exerted on the different points as desired. He illustrates the apparatus, and its effects on the patients, claiming the following advantages:

1. The most economical use possible is made of the corrective force by applying it sideways, and thus less force is required or the same amount of force will do more than in extension of the spine. 2. The force is applied to the spine while slack and not made tense by extension. 3. Side correction is made by one part of the appliance. 4. Correction of rotation is made by another part of the appliance. 5. The pelvis is held in a position which ensures some flattening of the lumbar curve, which in the upright position tends on account of the balance of the patient to bring about straightening of the dorsal curve. 6. Finally, it may be said that general pathologic considerations would seem to indicate that retention in the corrected position should induce changes in the shape and relations of the misshapen bones.

30. **Hydrotherapeutic Prescriptions.**—Pratt reviews the uses of hydrotherapy in the different forms of disease, and concludes with a series of some thirty-five methods of its application.

Cincinnati Lancet-Clinic.

April 2.

32 *Uses of the Gastrodiaphane in the Diagnosis of Certain Gastric and Abdominal Affections. Frank L. Rattermann.
33 Some Few Observations on Hamlet—Was He Sane or Insane? If Insane, Was He Responsible? A. N. Ellis.

32. **The Gastrodiaphane.**—Rattermann gives the history of the invention of the gastrodiaphane and the methods of its use. He thinks it is not more difficult for the patient to swallow than the ordinary stomach tube. It works best in lean persons. The operator should pass an ordinary stomach tube for several days to a week prior in order to accustom the pharynx to the sensation which is at first produced. In case of gastric ulcer the instrument should be used with caution, and never when blood has been vomited or passed by the bowels within a few weeks. It should never be used in severe cases of heart disease or chronic bronchitis, in the aged or very weak, or in any advanced cases of tuberculosis or immediately after hemorrhage from any internal organ. Six weeks at least should elapse before any attempt at gastrodiaphany. The light should not be burned continuously; it is well to cut it off and allow the lamp to cool. He contradicts Kuttner and Einhorn's assertion that the lamp never becomes too hot as not agreeing with his experience. The method can be practiced with the patient in either an upright or horizontal position. A dark room is not necessary, though preferable. It is not necessary to have the stomach completely empty. The size of the picture depends on the amount of water in the stomach. The shadow view on the abdomen moves upward and downward as the lamp is pushed down into the stomach. The picture during respira-

tion moves upward and downward on the abdominal wall as the result of the connection of the stomach with the diaphragm. He finds that one is enabled not only to recognize the transverse colon by the dark shadow line lying below the greater curvature of the stomach, but likewise the dark shadow of the liver above and to the right side, and even, under favorable circumstances, those of projections, as tumors, gall bladder or dislocated spleen, etc. Frequently the recti muscles produce certain shadows on the picture, and it has been noticed that the view darkens and brightens with each pulsation of the heart. He claims that the gastrodiaphane under favorable conditions can be of valuable service in differential diagnosis of certain tumors of the gall bladder and carcinoma of the pylorus or a completely descended kidney fixed by adhesions and on a level with a normally located pylorus, pyloric carcinomas, or a dislocated spleen or tumors. Lastly, in certain cases to clinch the diagnosis of carcinomatous infiltrations in the anterior wall of the stomach. While a simpler means may often be effective, nevertheless there are cases in which the instrument may be of very great assistance.

Southern California Practitioner, Los Angeles.

March.

34 Relationship of Diseases of the Bronchi and Lungs to Those of the Nose and Throat. Frank W. Thomas.
35 *Management of Pneumonia with Special Reference to Hydrotherapy. Simon Baruch.
36 Cotton Mather, Zabdiel Boylston and Inoculation. James G. Mumford.

35. **Management of Pneumonia.**—The plan of treatment recommended by Baruch consists : 1. In absolute rest and isolation. 2. Thorough ventilation, abundance of fresh air; plenty of oxygen in this manner will avoid the necessity of later oxygen inhalation. 3. Drink. The patient should receive from four to six ounces of water at 40 F. every hour. He often orders a few drops of hydrochloric acid or other placebo to be taken in four to six ounces of ice water every hour to insure regular administration. 4. Stimulation. This is unnecessary, except in alcoholics who are accustomed to it. Such cases may receive from ½ to 1 ounce of brandy every three or four hours, according to the previous habits. 5. Medication. Baruch is still in the habit of beginning the treatment of all cases of pneumonia with 8 or 10 gr. of calomel so as to clear out the system, given dry on the tongue and the mouth well rinsed with water mixed with calomel before it is swallowed, so as to prevent ptyalism and destroy diplococci in the mouth. Several copious movements of the bowels should follow this, if not, citrate of magnesium is administered. He says avoid the small doses of 1/10 of a grain so frequently administered. They disturb the patient and irritate the intestinal canal. Strychnin is sometimes useful when the first sound of the heart becomes feeble, and should be given hypodermically in doses of 1/60 to 1/30 gr. every six hours. Small doses of the coal tar preparations are sometimes good calmative agents. One dose of from 6 to 8 grains of ammonol will produce sleep and quiet the patient. It should not be given oftener than once in twenty-four hours. 6. Hydrotherapy. In children he uses the tub bath, not less than 85 F. with constant friction, for six to ten minutes whenever the rectal temperature is over 102. Sleep, if natural, should not be disturbed In adults he does not use the tub bath because of the disturbance to the patient. The toxemia in pneumonia is rarely so intense as in typhoid, and the temperature yields more readily. He therefore uses wet compresses consisting of three thicknesses of old linen in the shape of an old-fashioned oil-silk jacket or loose waistcoat, open at the shoulders: This is wrung out of water at 60 F., applied around the entire chest and snugly covered with a similarly shaped piece of flannel, a little larger in size, without any impervious covering. This is repeated every hour while the patient is awake until the rectal temperature reaches 99.5. It is never removed from the chest unless thoroughly warm. This application fulfills the following therapeutic indications: The gentle shock and reaction following it produces a refreshment of the nervous system; inspiration is deepened, dyspnea, which Baruch thinks is a sign of diplococcus infection rather than pulmonary obstruction, is relieved. The patient brightens up and feels refreshed. Heart failure is prevented. It acts as a direct tonic to the heart. The elimination of toxins is furthered by improvement in the circulation and the quantity of urine increased. Perspiration is another elimination process which is favored. The alkalinity of the blood has been shown to be increased. The temperature is reduced after each cold compress. The abstraction of heat is followed by a reaction which warms the damp linen. He says see to it that the nurse does not apply oiled silk over the compress and make a poultice of it, relaxing the vasoconstrictors and making the cutaneous circulation sluggish, which is not desirable. He thinks with this management the crisis is not often observed; lysis is the ordinary resulting process. After the acute manifestations have subsided, the temperature and pulse being normal, the patient may be allowed to rise, and after a few days ride out if the weather is propitious, even though the physical signs indicate that resolution is not complete. He has reduced by this method the mortality in his hospital practice from 50 per cent. down to only 12 per cent., which, considering the desperate character of the cases, many of them being poor Italians and persons of bad habits, is a very excellent percentage. He claims that this method is based on the conservative tendencies of the human organism, which must not be embarrassed by powerful medicine, but aided and encouraged. Careful watching of the patient and earnest attention to the minutest details are essential to success.

37. **Eye Defects in Students.**—The subjects of Swift's study were students in the State Normal School at Stevens Point, Wis. The tests included the usual ones for vision, the card test for astigmatism, the Maddox multiple rod test for muscle insufficiency, and diagnosing errors of refraction by means of the ophthalmoscope. All these methods were used for each subject, and their results are classified in groups. A summary of the observations is stated as follows:

> 1. Only 22.22 per cent. of the 216 students examined had normal vision. 2. Of those with normal vision only one failed to disclose some manifest error of refraction or muscle insufficiency. 3. Thirty-five of the 48 with normal vision showed manifest compound hyperopic astigmatism in one or both eyes, while of the remainder, 4 had simple hyperopic astigmatism and 4 others hyperopia. In most of the cases more or less muscle insufficiency was evident. 4. In 30 per cent. of those examined the vision of one or both eyes—the most defective where there was a difference—was below 20/30, while between 19 and 20 per cent.—nearly as many as had normal vision—were unable to read the 20/40 line at a distance of twenty feet.

39. **Eye Hygiene in Mexican Schools.**—Troncoso has inspected the eyes of the pupils in the Normal School of Mexico City, including more than 500 students, and reports the results. He finds that pure hypermetropia diminishes in proportion to the age, but hyperopic astigmatism becomes more frequent. The number of cases of myopia amounts to 19 per cent. The proportion of myopic cases in Mexico in proportion to some other countries is not considerable. The influence of race, he says, is notable. In place of the widely separated orbits of the broad-faced German, who has difficulty in obtaining convergence, we find the head of the Mexican native narrow, and convergence easy. The abundant and prolonged daylight, even in the winter time, also has a bearing on the comparative infrequency of myopia in Mexico, but the proportion of cases of ametropia is considerable. Fully 42 per cent. of the pupils in the Normal School have not sufficiently clear vision to enable them to follow the teacher's explanations on the blackboard, and 25 per cent. require such close approximation that it is incompatible with the functional integrity of the organ. A reform in school building it was supposed would relieve the condition. but this has not proved the case, and the detection and

correction of ocular and aural defects is necessary to check diseases of these organs in their incipiency. He pleads for the general adoption of systematic school inspection and a warning sent to parents of the defective children, calling on them to secure proper medical advice.

41. **Small Shot Injuries of the Eyeball.**—Moulton calls attention particularly to two forms of shot injury, those in which the shot perforates the lid or the orbit wall and impinges at a tangent on the sclerotic without perforating it, but with such force as to cause rupture of intra-ocular vessels and hemorrhage within the vitreous chamber. Another form is where the shot makes a puncture and counter-puncture in the globe, that is, passes directly through the orbit. In the first of these the prognosis, if guarded, is relatively good; in the second not absolutely bad, especially if the point of entrance does not involve the "dangerous region." Five cases are reported illustrating these injuries. His idea, he says, is to encourage in suitable cases the adoption of a reasonable conservatism in the treatment where a wound has been made by a body more likely than any other to have passed through the orbit or glanced off from it.

45. **Corneal Ulcer.**—The advantages of the Saemisch cut are noted by Gifford and the supplementing of the cut in severer cases with burning of the ulcer. In mild cases he would prefer to scrape it thoroughly and apply one of the milder caustic acids, with re-opening of the cut every twelve hours at least. If after twenty-four hours the progress of the ulcer is not certainly stopped, the edges of the cut should be cauterized so as to open into the anterior chamber. If this, in connection with a pressure bandage, does not produce constant leakage of the aqueous or a certain cessation of the infection, enough tissue should be burned out to insure leakage. He thinks the advantages of the Saemisch cut are due not only to the relief of tension, but also to the flooding of the parts with alexins or natural antitoxins and bacterolysins of the blood contained in the aqueous. He endorses the recommendation of Fox and Bulson of trichloracetic acid for the milder forms of ulcer. Since using it he has almost discontinued the use of iodin. In the severer forms, however, it is not to be relied on. If after a single application, however, it is evident that the infection continues, it is better to use the galvano- or Paquelin cautery. He thinks this latter is not used enough in eye surgery. It has the advantage of greater penetrating power and that it does not require to be so hot as to dazzle the eye of the operator and embarrass accurate use. He thinks it also of value in the removal of epithelioma; for burning out the stump of the optic nerve, and in the few cases when it is necessary to destroy the tear sac.

51 Mastoid Disease and Cerebellar Abscess. Seymour Oppenheimer.

47. **Septal Deviations.**—The modification of Krieg's operation here proposed by Stubbs is as follows: After the usual preparation and cocainization,

> With an ordinary scalpel an incision is made perpendicularly along the entire anterior edge of the triangular cartilage or side of convexity, this being facilitated by drawing the fleshy part of septum sharply to opposite side. With a small, flat, somewhat curved on the flat, perichondritome or elevator the muco-perichondrum is separated over the convexity. Then beginning at anterior edge of cartilage do the same on side of concavity. The field of vision is improved by having the assistant, who stands behind the patient to steady head, use one or two blunt hooks or retractors to open naris in place of nose speculum. If desired a stitch can be taken in fleshy portion of septum, which will include a strip of gauze. This will help to retract anterior edge of septum to opposite side. When both sides of cartilage are stripped the mucous membranes generally balloon to opposite sides and expose the cartilage in its entirety. The cartilage is now cut out preferably with a pair of Grünwald's alligator scissors. If more is desired to be removed superiorly or inferiorly, it can be trimmed down with a pair of Krause's fenestrated cutting forceps. Should there be a bony involvement in the deviation, continue the separation backward of periosteum, and remove the bone with a pair of fenestrated cutting forceps, preferably those of Laurent. If deviation involves only posterior half of cartilage, the incision in same can easily be made in front of convexity and muco-perichondrium separated only over concavity of deviation. With all deviation removed the linear incision can be stitched *or not*, as suits the operator, while moderate snug packing on both sides brings the muco-perichondrial walls firmly together and prevents an accumulation of blood between them.

He mentions the advantages of this operation as shortening the time, giving a better command of the field of operation, less hemorrhage, no flap being made that can be injured, preservation of entire intact mucous membrane, resulting straight and even septum, need of but few instruments, and these not special ones, the non-occurrence of perforation if the membrane is punctured on side of concavity, shortening of time of repair and the successful removal of the obstruction.

48. **Platinum Rhinitis.**—This condition has been observed by Lockard. The patient was a photographer and the attacks had been diagnosed as hay fever. They occurred only after he had taken up the use of platinum paper for photographic prints, and in the beginning never appeared unless he had been at work in the dark room for thirty to ninety minutes, and rapidly subsided, but at present they occur in a few minutes and never completely subside. On handling other prints the symptoms do not occur. As they are elicited by the use of the dry paper their chemistry need not be considered. He has seen four other cases, with almost identical histories. In all of them the absence of any ulceration or necrosis would indicate that the platinum action is of purely mechanical origin. He knows of no effective treatment except change of profession and discontinuance of work with this particular substance.

57 *Septum Narium in Aborigines and the Cause of Deviations of the Septum in General. W. Freudenthal.
58 *Case of Objective Tinnitus Auri. Arthur I. Weil.

53. **Antral Disease.**—Berens reports a case where an extensive operation of opening the anterior wall of the antrum was performed and the cavity was found full of myxomatous masses, granulation and pus. After freeing the antrum the sphenoidal cavities were also found involved, and had to be thoroughly cleared out. The operation is described in detail on account of the advantages which the author thinks it offers over the nasal route. The results have been so far good, though the age of the patient was not favorable, the condition of long standing and the damage extensive.

54. **Tuberculosis of the Larynx.**—Yankauer's article is a review of the recent literature on the subject.

55. **Middle Turbinate Hypertrophy.**—In this article by Brown disorders of the middle turbinate are considered as a very probable cause of many cases of hay fever, supporting Bosworth's contention. Brown has carefully examined the condition of this organ in his cases, removing the hypertrophied growths. He says few nasal operations are followed by such brilliant results as are often met with here. His own practice has been to remove a part of the bone in nearly all cases, and while he has regretted this in some instances, he has quite as often regretted that he did not remove more. He is doubtful whether any antitoxic or any other local or systemic medication will render unnecessary the intelligent surgical treatment of most of these cases.

57. **Septal Deviations.**—Freudenthal finds that deviations occur not only in civilized but in uncivilized races. Trauma may be eliminated as the cause in many instances, and the high arched palate has been disproved as a causal factor by Talbot. The most plausible explanation, and one that he has held to for a long time, is that of Chiari, that human individuals are asymmetrical. This asymmetry is most evident where the two halves of the body join together as in the septum. The side on which the growth is strongest will develop the most tissue, and convexity will take place and increase more and more until deflection results. In practice, however, we see

cases where the septum is almost as thin as paper in its convex part, and here he thinks the deposition of tissue must have stopped and a rarefying process set in on the concave side. The cause of this is hard to explain, but he thinks it is probably due, like the other condition, to an increased tissue building by the various human customs.

58. **Objective Tinnitus Auri.**—In the case observed by Weil the connection of the ear of the observer with that of the patient revealed a loud systolic murmur, synchronous with the heart beat, varying in intensity. The patient, of course, experienced symptoms much more actual and the hearing was impaired on both sides. The cause for these objective symptoms was not found. The heart, lungs, and chest were apparently normal. No signs of aneurism could be detected anywhere, no anemia and no venous hum in the neck. The ears, nose and pharynx are normal and also the appearance of the ocular fundi. He discusses the literature of this condition, and the causes that have been assigned to it, and shows how they have failed to explain it. He remarks, in conclusion, that where no aneurism can be determined and no marked anemia exists, the cause of persistent objective tinnitus will remain a mystery.

60. **Pneumococcal Bronchiolitis.**—Clark and Batman report a fatal case of pneumonia in which the examination showed that the large bronchi were free from inflammation and the alveoli were little affected. Bronchopneumonia in this case must be considered secondary. The bronchioles were the seat of the infection. The case should be regarded as one of capillary bronchitis, or preferably bronchiolitis, occurring in a young man aged 21. The inflammation was bilateral, affected all the bronchioles, and extended into the minutest subdivisions. The bacteriologic examination showed the *Diplococcus lanceolatus* to be the essential etiologic factor. The clinical diagnosis was pneumonia, probably associated with miliary tuberculosis. The case is also of interest in that it occurred during an epidemic of lobar pneumonia, in which over 3,000 individuals died in six months, and, in the great majority, of consolidation pneumonia, while in this case there was a diffuse affection practically free from consolidation.

62. **Bacillus Mucosus Capsulatus.**—Perkins finds that under this name are indicated a number of organisms described otherwise under various names, and closely related morphologically and culturally, but differing in certain characteristics. Fermentation experiments showed constant results that may be used as a basis for the separation of the different members of the group according to their ability to ferment lactose and saccharose. The organisms of the group are widespread, and have been found in almost all pathologic lesions which may be caused by bacteria. Such infections are exceedingly frequent in Cleveland, and appear to be almost exclusively due to the members of the *Bactrium aerogenes* division. These organisms may form gas from the body carbohydrates, either during life or just after death. The portal of entry of the infection appears to be the nose and mouth, and secondarily, the digestive tract.

64. **Pneumococcus Infections.**—Rosenow gives the following conclusions as justifiable:

1. With improved technic, using for inoculation large quantities of blood, the pneumococcus can be recovered in practically all cases of croupous pneumonia, and in obscure cases of pneumococcus infection blood cultures may be a diagnostic method of positive value. 2. Pneumococcemia in pneumonia does not mean an especially unfavorable prognosis, and it is to be regarded here, as in subcutaneous pneumococcus infections of the rabbit, not as an especially ominous or agonal process, but rather as an integral part of the infection. 3. There seems to be a diminution either in the number or viability, or both, of the pneumococci in the blood at the time of crisis. 4. The number of leucocytes in pneumonia in man and in the pneumococcus infection of the rabbit is an index to the degree of resistance, and the leucocytes probably constitute an important factor in combating the infection. The clinical observation that a high leucocytosis means a favorable prognosis irrespective of the presence of pneumococci in the blood is undoubtedly correct. 5. The hypoleucocytosis developing on a previous hyperleucocytosis during the course of many fatal cases of lobar pneumonia (and in pneumococcus infection of the rabbit), can not be looked on as due to the entrance of the pneumococcus cells into the blood stream, but probably rather as the result of an exhaustion of the resisting powers. 6. The leuoocytosis may be incited, at least in part, by soluble substances liberated by pneumococci. 7. It was not possible to establish any appreciable difference in the degree of virulence of the pneumococcus isolated early or late in the course of the disease, nor in the fatal or non fatal cases. 8. Fresh normal and pneumonic blood and serum have no bactericidal influence on the pneumococcus. Whatever other differences they may have, so far as this point goes, the serum from pneumonia patients behaves exactly as does normal serum. 9. The interesting question whether lobar pneumonia is the primary result of a direct local infection of the lung, or a secondary localization of a primary blood invasion, is as yet hardly ripe for final discussion, but that the latter does occur, at least in some instances, is not altogether unlikely. 10. Agglutination of the pneumococcus by pneumonic serum is constant, but the conclusion drawn by certain investigators that the voluminous sediment and the early clouding of certain immune sera in which the pneumococcus is cultivated are due to a rapid lysis of the cocci seems incorrect. It seems to concern a precipitate the result of acids which appear when pneumococci are grown in pneumonic serum. 11. The production of acids by pneumococci in pneumonic serum suggests that some of the toxic symptomss of pneumonia may be due to acid intoxication. This needs further study. 12. Since the viability and the virulence of the pneumococcus are preserved for a remarkably long period on blood agar, we have in this medium an important aid to all investigations of this micro organism. The constituent of the blood which has this rather remarkable effect is probably the hemoglobin. Blood-agar plates are valuable for differentiation of pneumococci and streptococci. 13. That the pneumococcus by its growth in rabbits produces a soluble hemolysin for the corpuscles of this animal is probably true. That this is either small in amount or unstable, or both, is likely.

72 *Local Treatment for Varicose Ulcers. Fred Fletcher.
73 *Shall Consumptives Be Excluded from the Schools? C. O. Probst.
74 Typhoid Fever in Columbus. Report of Commission.

71. **Vital Statistics.**—Wilbur calls attention to the importance of vital statistics, and illustrates the inconveniences of their absence by cases observed by the Chicago Health Department and the author's own observations in Michigan. He urges physicians to favor legislative action in the matter.

72. **Varicose Ulcers.**—Fletcher recommends for the treatment of varicose ulcers the saturation of a good-sized piece of gauze with bovinine, and its application to the ulcer, covering it over with gutta-percha tissue, and changing it every six hours. This, or a modified form of treatment, using gauze with bovinine or salt solution, is applicable to all varieties of varicose ulcers.

73. **Consumptives, Shall They Be Excluded from the Schools?**—Probst discusses the question whether consumptive teachers or scholars should be excluded from schools. He remarks that if consumption were transmitted as smallpox or scarlet fever, there would be no need to discuss the question, but it is not. It is not necessary to enforce absolute rules excluding consumptives, but it is essential that they should be educated to carry out necessary measures to prevent the communication of the disease. They should also be dissuaded from attending school for their own sake. If teachers and children were thoroughly instructed in regard to this matter, much good could be done.

75 *Serum Treatment of Summer Diarrhea. John Zahorsky.
76 *Physicotherapy in the Cure of Cancer. J. A. Riviere.
77 *Experiments on the Preservation of Milk. C. A. Snodgrass.
78 *Brief Note on Frost-bite in Young Children. W. A. Hardaway.
79 Pregnancy Complicated with Cyst of Ovary. Operation, Recovery. Report of Case. Charles H. Dixon.

75. **Serum Treatment for Summer Diarrhea.**—Zahorsky used two forms of anti-dysentery serum prepared by Parke, Davis & Co., the first in which only one race of the micro-organism was used, which was called monovalent, and the other in which several varieties of dysentery bacilli were employed, called polyvalent. He reports cases treated with both, and concludes that the monovalent anti-dysentery serum was too uncertain in its action for general use, but the polyvalent serum should be given a trial in all cases of summer diarrhea.

76. **Cancer.**—The physicotherapy used by Riviere consisted in radiotherapy, static breezes, franklinization, high frequency currents, static baths, arsonvalization, etc. The effects were the disappearance of the edema, engorgement and indurations, cessation of pain, cicatrization, disappearance of cachexia and disappearance of the tumor. He thinks it a useful method to obtain retrogression of malignant tumors, sedative action and disappearance of glandular engorgement, besides being the only possible recourse in inoperable neoplasms, especially the vegetating and ulcerating forms and in recurrence after operative ablation. The field exposed for treatment should include a wide area around the tumor.

77. **Milk Preservation.**—Snodgrass, the city bacteriologist of St. Louis, says the object of his experiments was to determine the effect on milk of ordinary room temperature without the use of chemical preservatives, the effects of refrigeration or the addition of formalin in various proportions and the rapidity of multiplication of typhoid bacilli in sterile milk without preservatives. He tabulates his findings, and concludes that the ordinary commercial milk kept at room temperature is generally unwholesome at the end of twenty-four hours, to say the least; it is sour to the taste. We must also infer that the ordinary commercial milk kept at 44.6 F. remains wholesome for four days or more. Ordinary commercial milk does not remain wholesome for twenty-four hours when kept at room temperature with the addition of formalin 1 in 25,000 or 1 in 50,000, and questionably so when the dilution is made 1 in 10,000. In adding formalin to refrigeration the wholesomeness of the milk is improved only when the dilutions are made 1 in 10,000 and 1 in 25,000. The rapid increase of typhoid bacilli indicates that milk infected with pathogenic organisms whose rate of increase is about the same, becomes rapidly dangerous at a temperature of 77 F. Refrigeration, therefore, he concludes, is far more efficacious than the use of formalin without refrigeration in the preservation of commercial milk.

78. **Frost-Bite in Children.**—Hardaway reports three cases in which there was an erythematous area on the face with considerable discomfort, increased temperature and slight enlargement of the cervical glands. The children had been exposed out driving in very cold weather, and the condition was practically a frost-bite. He thinks this accident is probably well known in the colder climates, but most physicians seem to be unfamiliar with it. In all cases the child had a fair complexion and light hair.

83 *Curative Effect of Erysipelas on Atrophic Rhinitis. I. Valentine Levi.
84 Venesection as a Therapeutic Measure in Lobar Pneumonia. G. A. Shank.

80. **Puerperal Eclampsia.**—Tyson takes up the point of the use of morphin in puerperal eclampsia, and holds that it is safe in case the kidney is capable of eliminating it. Since most cases of puerperal eclampsia occur in connection with parenchymatous nephritis the results are often brilliant. Should it happen, however, that the condition is an interstitial one, especially in cases where nephritis preceded the pregnancy, its use is attended with very grave risks. In order to secure the best results of treatment in uremic convulsions by hypodermoclysis with normal salt solution, he holds that sweating should precede the infusion, as it is possible, he thinks, to overload the venous side of the circulation and dangerously dilate the right heart. He thinks we would do well to use blood letting more frequently in other than puerperal cases, or by sweating to make room for salt solution subsequently introduced. The depletion removes a certain amount of toxic matter, which is still further diluted by the salt solution.

81. **Pneumococcus Infection.**—The direct contagion of pneumonia is discussed by Edsall and Ghriskey, who report an interesting series of cases occurring in the Episcopal Hospital, Philadelphia, in April, 1903. There was a patient there suffering from a severe attack of pneumonia. He was evidently overwhelmed with pneumococci, for the blood cultures gave a free growth of these organisms. The patient died, and although the bedclothes were changed, the bed aired and the ward cleaned, the man who succeeded him in his bed showed a growth of pure pneumococci in his blood in twenty-four hours after his admission. There were no other signs of pneumonia, excepting a fairly marked bronchitis. The next day he was transferred to another ward, and the patient following, a man of 22, with sciatica, was admitted and happened to be placed in the same bed. He remained there about thirty-six hours, and in less than two days after being transferred he developed a pneumonia of the entire left lower lobe, which was mild. Within a day or two a boy of 14, with tubercular meningitis, was placed in the same bed after its vacation, and two days after his arrival showed an increase of temperature with leucocytosis of 14,000; his respiration grew rapid and remained so. It was never determined that he had pneumonia, but in view of the facts concerning the other cases the authors think that he must have had some other form of pneumococcus infection. Five days after having been placed in this bed he died. A postmortem could not be obtained. The day after this a patient, an adult man of 42, with mild alcoholism, was placed in the same bed, and two days later showed a sudden rise of temperature, pain in the right side, and later in the day had clear signs of pneumonia of the right lower lobe. This took a mild course, and the man recovered. The day after this man's admission there was placed in the bed opposite, and about ten feet away from the one occupied by him, a patient in the first week of typhoid fever. Two days later a blood culture was taken from him, and a pure culture of pneumococci was obtained. He, however, went through a mild course of typhoid without any signs of pneumonia or other complication, and recovered without any special incidents. When the second case of pneumonia developed in bed No. 2 and the second pure culture of pneumococci was obtained in the ward from a typhoid patient, it appeared to the hospital authorities that pneumonia contagion was occurring, and the ward was formalinized and no cases occurred subsequently. The reason why the beds were so rapidly occupied was because that ward was used for the temporary detention of noisy patients, who were kept there for only a short time. The epidemic, while there were only two cases of pneumonia, is of interest, especially in connection with the cases occurring without pneumonia, but with pneumococci in the blood. Edsall and Ghriskey think the ideal method would be to isolate cases of pneumonia, but this is almost impracticable at present. It would be a good thing to make it a reportable disease, and the practice of disinfecting after almost every infectious disease, they believe, is getting to be more general. The observations are of interest also in relation to the period of incubation. They show that this may have been less than forty-eight hours in one case, and only a little more than that in the other. Other authors, Weibell for instance, have observed that the period of incubation may be very brief.

82. **Epistaxis in Nasal Diphtheria.**—McKee describes a series of cases, and thinks that in connection with other facts

they justify the following views: 1. That the slight staining of nasal discharge with blood, either in mild or severe nasal diphtheria, would seem to be due to the severity of the local disease. The nasal mucous membrane bleeds very easily. In subacute cases the moderate epistaxis may be dependent on the depth of the inflammatory process. Ulcers may exist on the nasal septum. 3. The slight or moderate hemorrhages in the more acute cases are probably dependent on the toxemia. Of course, the idiosyncrasy of the individual plays its part. 4. The alarming or even fatal nasal hemorrhages in severe diphtheria are always dependent on profound toxemia. In conclusion he summarizes as follows:

> 1. Staining of the nasal discharge with blood is quite commonly seen in nasal diphtheria, and epistaxis of moderate severity is not infrequently observed. 2. Nosebleed is a symptom of much diagnostic value, for it may suggest the possibility of nasal diphtheria in any case, but particularly in the dangerous (to the community) mild case. Among the causes of epistaxis, diphtheria of the nose should be accorded a separate and prominent place. 3. In malignant, mixed, or strepto-diphtheria (Northrup) of the nose, epistaxis may be most alarming and may even be the immediate cause of the fatal termination.

83. **Erysipelas and Atrophic Rhinitis.**—Levi reports a case of atrophic rhinitis which recovered after a third attack of epistaxis, and a subsequent operation revealed no evidence of the former condition. He does not explain the mechanism of the cure, but suggests that the pathology of the two diseases is diametrically opposite. In one we have anemia and atrophy, and in the other hyperemia and swelling. The action of the bacterial products of erysipelas on certain other diseases is significant. Beside the case here reported he finds but three other similar ones on record.

1. **Coagulation of the Blood in Albuminuria and Eclampsia.**—Douglas' article reports the results of the studies of the coagulability of the blood in pregnancy, puerperal albuminuria and eclampsia; also in cases of healthy puerperæ, healthy pregnant women and healthy non-parous women. The methods are given in detail, the tests being made by blowing out the blood in a series of tubes within a certain period after filling, noting the time when it is impossible to completely free the tube from blood showing that coagulation has commenced. He finds that the average, shortest and longest coagulation time in all the different classes examined in between three and four hundred observations were very close to each other. There is nothing to support the theory of increased coagulability in this special class of cases, only that in pregnant albuminuria there is a little shortening of time. Douglas concludes from the observations that there is little difference in the coagulation time in healthy pregnant and puerperal women or in eclampsia before and after delivery, and that there is nothing—so far as the study of the coagulation of the blood goes—to support the view that the thrombi found in certain organs in fatal cases of eclampsia are due to increased coagulation.

2. **The Site of Impregnation.**—Two cases are reported by Cripps and Williamson which seem to throw some light on the question of the site of impregnation. In one tubal gestation occurred after complete removal of the ovary on the same side. The authors think that it is improbable that any portion of the oöphoron was left in the operation for dermoid cyst which had been performed and reject as a probability the existence of a third or accessory ovary on that side. Cases of such have been reported, but few have stood the test of examination. Where pregnancy has occurred after a double ovariotomy it has been demonstrated in some cases that portions of the organ were left or the author's description of the operation indicates the impossibility of absolute certainty of the removal of the whole organ. In the second case there was a pregnancy after resection of both tubes. In the first patient there was little doubt but that it was a case of what may be called an external migration of the ovum, but in what part of the course the impregnation occurred can not be said, possibly, as suggested by Sippel, it was in the abdominal cavity. It is difficult to understand the course of the pregnancy in the second case after the removal of a portion of the tube. It can hardly be that the severed ends were ultimately united and the canal again patent, but it is possible that a process of absorption may have occurred in the walls of the tube which were in contact with one another, ultimately leading to the formation of a fistula between the two portions and establishing the continuity of the canal.

3. **Ventrofixation of the Uterus.**—Sinclair criticises the various processes of supporting the retroverted uterus, rejecting absolutely Schultze's method and considering Schucking's operation as a timid and dangerous one. Alexander's operation with its modifications has a value in certain cases, but the operation which appears to him the best for the treatment of chronic ventrofixation is the one suggested by Olshausen in 1886. The tests which such an operation should stand appear to be: 1. That it should be devoid of danger with ordinary care; 2, must be easy to perform and the operator know that he can finish it with an absolute certainty; 3, must relieve the symptom; 4, must produce no new ones; 5, must leave the patient free from danger and in a condition for active exertion; 6, it must stand the strain of pregnancy, parturition and the puerperium as if it had never been done; 7, the uterus must afterwards continue to maintain the position it was placed in. To obtain the desired results he says the fundus uteri and the round ligaments must be strictly safeguarded and another important point is to effect complete and permanent adhesion of a sufficient area of the anterior surface of the uterus to the abdominal wall. Kelly's method is criticised, and the details of the operation as performed by Sinclair are given as follows:

> In performing the operation of ventrofixation I have discarded all suture material except catgut and the finest silk thread which can be conveniently manipulated. At first I used to try to close completely the vesico-uterine fold, but now for years I have introduced for this purpose only two catgut sutures, one at each side, well below the lowest point of the abdominal wound, while the uterus is firmly pulled upward by means of an ordinary volsella inserted in the center of the fundus and manipulated by an assistant. This is *quite sufficient practically* to close the fold without interfering with the distension of the bladder, and it is more of a preventive to any possible insinuation of intestine than shortening of the round ligaments, to the extent practiced by most operators, can be. The next step is *to suture the peritoneum* at the edge of the wound on each side. The fine silk sutures are introduced from the outside surface of the parietal *peritoneum*, passed through the peritoneum, and after taking a good hold of the uterus low down and near its margin, they are brought back through the peritoneum and firmly tied. The knot is thus always extraperitoneal. Two of such sutures are, as a rule, introduced on each side. The same process is now continued, with the addition that the sutures include the fascia as well as the peritoneum on each side. *The* transverse sutures are next introduced. These are two or three in number, consist of fine silk, and include fascia and peritoneum at the sides, and each takes a fairly extensive hold of the anterior surface of the uterus. The highest of the sutures is placed about halfway *up from the* isthmus to the fundus. In complicated cases, and when the prospect of pregnancy is very remote, the sutures have been placed occasionally a little higher, though not often. All the sutures that penetrate to any part of the uterine tissue are buried sutures *at the finish*; or, *if* any suture includes skin as well, it is never left for more than three days, usually only forty-eight hours. There must never be suppuration in the tract of this suture. The highest transverse suture should always be buried. The abdominal wound is closed in the usual way, and it is an advantage to suture separately the edges of the fascia with catgut. The last step in every case is the introduction of a glycerin-pad pessary into the vagina to press forward and support the uterus during the formation of adhesions. The patients are kept in bed for a month or six weeks, and they are advised to lead invalid lives for several months.

There is hardly ever, he says, the slightest reaction in the simple cases, and the operation has stood the tests of efficacy given above in nearly one hundred patients. A considerable proportion of the patients have borne one or more children since the operation.

4. **A Warning Sign During Labor.**—The sign here described by Daniel is a sudden, spasmodic, diaphragmatic contraction from an attempt at respiration, while the child is still unborn; is usually communicated to the head of the child, through it to the forceps if these happen to be embracing the head. He thinks the movement is characteristic enough to be always recognized. It is a sort of double or duplicated movement repeated in quick succession. The main indication for this condition is to deliver the child as quickly as possible, even at the risk of a moderate amount of perineal rupture.

9. *Pancreatic Disease.—Robson's second* lecture commences with a classification and description of the etiology and anatomy of the pancreas as explaining the etiologic factors and the symptoms of acute, subacute and chronic pancreatitis, together with cystic and hemorrhagic conditions. He recognizes simple catarrh of the pancreas as a species of disorder as much as catarrhal jaundice. As regards the diagnosis he quotes Fitz' rule with approval: "Acute pancreatitis is to be suspected when a previously healthy person or a sufferer from occasional attacks of indigestion is suddenly seized with violent pain in the epigastrium, followed by vomiting, collapse, and in the course of twenty-four hours, by circumscribed epigastric swelling, tympanitic or resistant, with slight rise of temperature." In case of laparotomy fat necrosis is almost pathognomonic. The urinary tests for pancreatic crystals should not be neglected as a positive reaction has been obtained in all cases of acute pancreatitis in which it has been employed. As regards treatment, pain at the onset usually requires analgesics and shock may call for stimulants which may have to be given by enema. The early evacuation of septic material is important. Early exploration from the front, through the

middle line above the umbilicus or from behind through the left costovertebral angle is indicated to relieve the tension, secure drainage, evacuate septic material and arrest hemorrhage. The after-treatment is usually the combating of shock and keeping up the strength until the *malcrics morbi* can be thrown off. An exploratory operation would help the diagnosis in revealing a fat necrosis if it exists. Robson has operated in 4 cases of acute pancreatitis, with 2 recoveries. In 2 cases in which operation was refused death occurred in one patient at the end of the third day, and in the other at the end of a week of illness the patient succumbing with great suffering. There is no hard and fast rule between subacute and acute pancreatitis. The slower onset, longer course and more hopeful outlook indicate the propriety of the division. There is no reason in subacute cases why surgical treatment should not be attempted in the early stage in many cases. Robson has had 8 cases of abscess of the pancreas under his care; 6 were operated on and recovery took place in 5, though the relief was only temporary in 2. In the eighth case, not operated on, the abscess burst into the bowel and discharged. He also found 7 other operations reported with 3 deaths, making a total of 5 deaths in the 14 operations. Chronic pancreatitis is an interstitial change leading to the formation of fibrous tissue. It may be interlobular, exerting pressure on, and atrophy of, the true glandular substance; or interacinar, in which the tissue invades the islands of Langerhans, interfering with the metabolic function and producing glycosuria. In interstitial pancreatitis the pancreas is uniformly swollen, the harder lobules have the feeling of being mapped out and differentiated, very different from the feeling of the healthy gland and also varying from the hard nodular character presented by cancer of the head or body of the pancreas. The treatment is first to aim at the cause, such as gallstones, pancreatic calculus, duodenal catarrh, etc. But when the medical treatment has had a fair trial—not too long continued—and a condition of jaundice and loss of weight continue with signs of failure of the pancreatic digestion and metabolism appear, surgical treatment should be carefully considered. The obstruction should be removed and drainage established in the bile ducts. The author thinks that the operation sometimes arrests the process of disorganization, though it does not cure the lesions that have already been produced. He finishes his lecture by giving the statistics of operations which show the small mortality in his own cases of 3.9 per cent. and in others of 12.9 per cent.

10. **Antituberculosis Serum.**—Marmorek explains his method and the results which he claims. He first tried his method on the severer class of cases, and in some had brilliant results. He finds that the duration of the tuberculosis has much to do with the results of the serum treatment. In the very severe cases of long standing with large cavities, etc., the prognosis is unfavorable as far as the serum is concerned. Marmorek reviews the effects of the serum on fever, infiltration, dyspnea, expectoration, hemoptysis and other symptoms. Surgical cases he considered as equivalent to the slighter lung cases, for the lung is a tissue that has a less tendency to repair than other parts, and while his experience has not been so great for surgical cases, he claims that even the severe ones, such at Pott's disease and hip-joint tuberculosis may be cured by the exclusive use of the serum. The tolerance to the serum with his method he thinks is absolute. The injections seem to agree more and more with the patient as they are continued. As a general thing, the dose should be adapted to the individual constitution and the state of the disease. A series of daily doses during four or five days agrees well with the patient, especially if between each two series there is an interval of three or four days. After two or three series of injections it is well to discontinue them for a week or a fortnight. For the rather chronic cases the dose of Marmorek's serum is ordinarily 5 c.c., while in the acute cases as much as from 20 to 30 c.c. may be used daily during the week. Even children bear this well. The reaction takes the form generally of the well-known serum erythemas which disappear in two or three days and discommodes the patients very little. The results of his treatment, he claims, are at least satisfactory.

11. **Urinary Segregation.**—Bickersteth's article reviews the history of attempts at urinary segregation, speaking especially in favor of Luys' method in which a catheter of a special form is introduced into the bladder, fitting the lower portion with its curve, and then by the use of a chain retractor a rubber membrane is drawn out, quickly dividing the organ into two different portions, thus enabling the separation of the urine from the two kidneys. The tests of renal efficacy which he mentions are the estimation of urea with Little's ureometer, cryoscopy, which he considers is of much value in certain cases, and the methylene blue test. He thinks that our power of accurate diagnosis in certain diseases of the kidney has been very greatly advanced by this method. In the histories of the various methods of urinary segregation he mentions Harris' segregator as the first practical appliance, but objects to it on account of its causing the patient pain.

33. **Hygiene of Infancy.**—Pinard reviews the regulations decreed by the mayor of Villiers-le-Duc in regard to the hygiene of infancy. The mayor is a native of the small place and a physician, and his regulations are not all legally enacted, but are more in the nature of advice which his position renders authoritative. The mortality has been reduced to zero. Every child born in the community during the last ten years is alive and well to-day. The mortality had been 20 to 30.8 per cent. of the births during the previous decades for a century with the exception of a single decade, during which the present mayor's father—likewise a physician—had been the incumbent and devoted much attention to infantile hygiene. The regulations include one to the effect that every needy pregnant woman, married or not, must inform the mayor of her condition before the seventh month and state the name of the midwife whom she wishes to have attend her. The midwife is then sent by the mayor to examine the woman, to ascertain that there is no albuminuria, no fetal or maternal dystocia nor vicious presentation. She is paid $1 from the public funds for each visit. If the midwife finds anything abnormal the mayor is notified and he sends a physician selected by the pregnant woman, to take charge of the case. Every parturient assisted by the community receives 20 cents a day during ten days after the confinement if she remains in bed. This amount is paid to her at the end of the ten days. If she gets up before this limit she forfeits this sum. Other regulations specify points in regard to the feeding, fortnightly weighing of the infant, etc., and one promises a reward of 40 cents a month which is paid to every woman who has brought up a child to

the age of one year in good condition, breast or bottle fed. This sum is paid to her at that time, computed for every month during the year that the infant has been in her charge.

34. **Fractures of the Radius from Automobile Cranks.**—In starting an automobile the chauffeur pushes the crank until the motor starts to work, when he then lets go and the crank returns automatically to its place. But sometimes the gas lights prematurely and the small explosion drives the crank back unexpectedly. If the chauffeur has been cautious enough to take away his hand no harm is done, but if the returning crank pulls his hand or hits his wrist it is liable to do considerable injury. Walther has observed a case in which the wrist was literally torn out and months elapsed before the injury had healed. Lucas-Championnière has observed a number of instances of fracture of the radius from this cause. In 2 subjects the crank did not hit the wrist, but the hand, still holding the crank, was thrown backward with great violence. The mechanism of this fracture is the same as when we take the hand of a cadaver and break the bones by turning the hand abruptly backward. He describes the various forms of these fractures and their mechanism. In the above cases it was a "tearing out" while a "pushing in" causes more deformity. In these cases under discussion there is fracture but no deformity. There is no necessity for reduction; the parts can be easily held in place, without immobilization or vigorous compression. The parts heal finely and promptly under mobilization and massage applied from the first. In other cases the chauffeur has withdrawn his hand, but the crank hits his forearm and fractures the radius by direct impact. The left arm might be the injured one in this case, while the "tearing out" fracture can occur only in the right arm. The localization of the pain, crepitation, and impossibility of supination and pronation are characteristic for this fracture by impact. Sprains are frequent and in one case both bones in the leg were fractured as the subject was standing too near the crank. The fracture may occur likewise by impact of the crank on the "heel of the hand," and also by "tearing out" if the chauffeur attempts to restrain the movement of the flying crank. The swelling of the tendon sheaths and of the joint is the most prominent symptom, and no attempts at reduction should be made, while the dressings should be as simple as possible without fixation. The parts heal rapidly. The chauffeur may be able to steer the automobile after the accident, but this does not disprove the fracture, which may be readily established by radiography. He adds that automobilists may accept this form of fracture and regard it with as little concern as jockeys and bicyclists have learned to regard fracture of the clavicle, a professional injury which does not prevent their continuing in the race. Chauffeurs should be warned not to hold the crank too firmly, although the grasp of the crank may be involuntary in nervous persons and prevent the rapid withdrawal of the hand. Experienced chauffeurs state that the accident sometimes occurs from imprudence in regard to the management of the motor before starting the machine.

Semaine Médicale, Paris.

35 (XXIV, No. 11.) *Thyroid Grafts in Man. H. Cristiani (Geneva).—La greffe thyroïdienne chez l'homme.

35. **Grafts of Thyroid Tissue.**—Cristiani has long been experimenting along this line and published works on the subject in 1895. His research on animals showed that the graft must be homologous, the transplanted tissue must be normal and alive, the grafts very small and numerous, and transplanted into regions well supplied with blood. In this, his latest communication, he describes 3 clinical cases in which he tried thyroid grafting. The first subject was a young woman who required operation on the neck for a non-thyroid affection. Her thyroid gland was normal and scraps from it were implanted in her own back, between the clavicles, and in a myxedematous boy of 12. The boy's thyroid gland had been extirpated and he was grafted with thyroid tissue from the first case, from a woman of 34 affected with goiter, and also with scraps of his own thyroid gland. The woman of 34 was grafted with scraps of her own thyroid, which was but slightly altered, and with scraps from the thyroid of the boy. There were thus six different kinds of grafts: 1, normal thyroid tissue transplanted into a normal subject; 2, much altered thyroid tissue grafted on an apparently normal subject; 3, slightly altered tissue in a normal subject; 4, normal thyroid tissue in a distinctly pathologic organism; 5, manifestly altered thyroid tissue in a pathologic organism, and 6, slightly altered thyroid tissue in a decidedly pathologic organism. Portions of the transplanted scraps were excised from two to six months later. The findings demonstrated that it is possible to graft human subjects with thyroid tissue and thus obtain a permanent neothyroid organ, the same as is possible with animals. The results from the anatomic point of view are excellent when normal thyroid tissue is used. They are still positive when only slightly altered thyroid tissue is grafted, but a distinctly pathologic tissue undergoes degeneration. The technic which he has found most advantageous is to cut up the thyroid tissue into very thin slices with a sharp knife without crushing or impairing its vitality in any way. These scraps are then floated in physiologic salt solution and injected with a syringe through a trocar subcutaneously into the subject. He has found that thyroid tissue from the rat or rabbit thus prepared would keep for an hour without compromising its vitality, while it kept only ten seconds exposed dry to the air. He thinks that by this simple technic it is possible to graft a subject with thyroid tissue as a means of relieving disturbances due to the missing thyroid function, or as a preventive measure against cachexia strumipriva after extirpation of the thyroid gland. In spontaneous myxedematous hypothyroidia the grafts are liable to persist and develop if the tissue employed is not too much altered. His experiments further establish that when the subject is suffering from almost total suppression of the thyroid function the demands on the transplanted thyroid tissue are so excessive that the graft becomes degenerated from hyperfunction. On the other hand, when the subject already has a normally functioning thyroid gland the graft dies from disuse. The best results are attained when moderate functional demands are made on the graft, as in partially thyroidectomized animals. The grafts are much more successful and display remarkable vitality with a tendency to hypertrophy under these conditions.

Berliner klinische Wochenschrift.

38 Minimum Requirements for Milk for Infants. C. S. Engel (Berlin).—Welches sind die geringsten Anforderungen die an eine Säuglingsmilch zu stellen sund?
39 *Zur Diagnose und Behandlung besonders der cardialen Form der Insomnie. L. Feilchenfeld.

36. **Origin of Tuberculosis.**—Spengler's protest against von Behring's views in regard to the origin of tuberculosis is based on numerous facts, among them his constant findings in cadavers of tuberculous children that the intestines are free from foci and bacilli, and that the primary localization is invariably in the bronchial glands. The bronchial glands were always found tuberculous in the cadavers of children who had succumbed to tuberculous meningitis. These facts speak for inhalation as the mode of infection. He believes that the predisposition to tuberculosis, the "phthisic habitus," is in reality merely the indication of an already existing, closed tuberculous focus somewhere in the body. The effect has been mistaken for the cause, as often happens, but an injection of tuberculin will clear up matters. Every human being, he thinks, who has reached the age of 30 has offered the tubercle bacillus one or more opportunities to settle and develop one or more local foci. A tuberculized subject, however, is far from being a phthisic. A certain proportion of the subjects thus infected become phthisic, others spontaneously recover and in the rest the affection remains localized and latent, although it may flare up later.

39. **Diagnosis and Treatment of Cardial Form of Sleeplessness.**—The heart may be regarded as the principal factor in that form of insomnia in which the subject goes to sleep naturally, but wakes up after an hour or two, suddenly, with a feeling of distress, usually palpitations and slight oppression in the chest. He tosses for hours in bed thereafter with no relief in sleep

until nearly morning, when he falls asleep again. Feilchenfeld ascribes this form of insomnia to a weakness of the heart muscle. The mild forms of muscular weakness are first revealed by this sleeplessness. The subject goes to sleep more readily when he lies on his left side, but wakes sooner. Examination of such persons has shown that after reclining long on the left side the apex beat is displaced to the left, almost into the axilla, and broadened, the pulse small and rapid, and symptoms of dyspnea are observed. The trouble is due to passive interference with the circulation as the subject reclines on his left side. This causes transient dilatation of the heart, and this in turn the symptoms experienced. The valves may be displaced also and this entails the symptoms of disturbed compensation, the restless sleep and premature awakening. He advances other theories to account for the symptoms observed, but all point clearly to the heart, and treatment should be directed to this organ. The subject is usually tired, predisposing to sleep, but lacking the full amount of fatigue necessary to induce sound sleep. He has 50 or 75 per cent. of the amount of fatigue needed, as it were, and treatment should aim to supply the missing 50 or 25 per cent. This is realized by incredibly small amounts of a narcotic. He has been very successful in this cardial form of insomnia with a combination of minute doses of digitalis and morphin: .015 gm., digit pulv. and morphin .0025 gm., given just before retiring. When the irritation proceeds from the intestines he finds it useful to administer sulfonal in .25 gm. doses two or three times during the afternoon. The smallest doses should always be tried first before resorting to larger ones. and sometimes they prove effectual when the larger doses fail.

45 Zur Technik der Paraffin-Injektionen. A. E. Stein (Wiesbaden).

40. Early Differentiation of Severer Cases of Appendicitis.—The Journal in abstract No. 90, page 686, mentioned Moszkowicz' announcement in regard to the value of a free serous exudate in the peritoneum as an early sign of the severer form of appendicitis, thus enabling the grave cases to be differentiated early, before serious symptoms have developed. Haegler here describes the results of experimental research which corroborate his statements. The serous effusion occurs in every case, but its quantity is proportional to the amount and the virulence of the germs or their toxins or of both. The peritoneum reacts to every irritation with a serous effusion proportionate to the intensity of the irritation. The large extent of effusing surface causes the accumulation of large amounts of fluid, but absorption keeps pace with it and compensates it under ordinary circumstances. In his experiments on animals he found that injection of cultures or toxins of the intestinal bacteria had the greatest irritative action, especially the anaërobic varieties, only equaled by that of the extremely virulent pus germs. This free serous or hemorrhagic effusion may be regarded as a protecting device against the toxins. If adhesions are not thrown up at once the contact of the toxins is followed by the effusion of a fluid to dilute and render them harmless. In local inflammatory affections of the intestinal wall, free effusion in the peritoneal cavity may, therefore, be ranked as an unfavorable sign. It shows that there is no tendency to wall off the irritating agents and that large amounts of very virulent toxins and possibly of the germs themselves, have irrupted into the open abdominal cavity or are continually finding their way into it.

43. Silver Wire Suture of Bones.—Grisson remarks that almost any method of suturing the bones with silver wire answers its purpose in case there is no suppuration. If there is suppuration it is sometimes necessary to remove the wire, and for this reason he recommends the technic which he illustrates, as with it the wire can be untied and withdrawn with ease. It is passed through the bone stumps as usual, forming a U. There is a knot in the right end, and this knot is drawn close against the bone. The left end is then brought to the right end as it emerges from the bone, and is passed around the right end, close to the bone, below the knot, after which its loose end is drawn down with forceps to form a loop underneath its horizontal portion. Both wires thus emerge through the wounds at the same point, and by pulling on the unknotted end it becomes untied and the wire can then be withdrawn by pulling on the knotted end. The technic is merely that of the ordinary sailor's knot with which rowboats are fastened.

46. Consent to Operations.—Chrobak comments on the lessening degree of confidence in the physician and the increasing tendency to hold him responsible for failures to cure. He thinks that the matter of self-protection of physicians and surgeons in this respect should be brought up for discussion at some general congress. He makes a practice of exacting from every patient a written consent to his intervention. The chart for each hospital patient contains a line to the effect: "I herewith declare my consent to the operation and every intervention which may be deemed necessary during it." This line is written or signed by the patient as a routine procedure, and as every one does it, those facing important operations are not terrified by any exception being made in their case. He has never had one refuse to sign. He always obtains the consent of the husband likewise whenever practicable, as he still shudders at remembrances of cases in which the husband lost his wife without any intimation that she was to be operated on or was in danger of any kind.

49. Manual Detachment of Placenta Without Gloves.—Ahlfeld mentions that manual detachment of the placenta has been done fifty-three times in his experience of 6,800 births to 1904. No gloves were used. Five of these 53 women died, 2 from hemorrhage and the others from pre-existing lesions. In not a single instance could the manual intervention be regarded as a factor in the mortality. As his mortality was thus zero, although gloves were not used, the similar lack of mortality in cases in which gloves were used can not be cited as an argument in favor of gloves.

51. Phenomena of Precipitation.—This communication issues from the Frankfurt Institute of Experimental Therapy, in charge of Professor Ehrlich. A number of new facts in regard to flaky precipitation are reported, among them the confirmation of the assumption that capillary electric phenomena are concerned in the phenomena of precipitation. In precipitation by the agency of salts, that ion of the salt is the determining factor which bears the opposite electric charge to the charge borne by the particles in suspension. The rôle of the precipitating cation of the salt may be assumed by an electropositive colloid. The latter has likewise a precipitating action on electronegative suspensions or colloids. Colloids in themselves unable to induce precipitation, acquire this property on addition of a small amount of the salt—not enough in itself to induce precipitation.

52. **Agglutination by Blood of Jaundiced Subjects.**—Steinberg refers to agglutination of typhoid bacilli and states that the blood serum of persons with intense icterus had no agglutinating power in his tests. If agglutination occurs in case of icterus it can not be due to the presence of the bile in the blood, but to the same factor that is causing the icterus.

53. **Typhoid Bacilli in Feces and Urine of Convalescents.**—Herbert describes an epidemic of 98 cases of typhoid in a public institution; 59 of the subjects were taken sick within five days. Infection was clearly traced to 2 cases of typhoid in the institution in the last week of July. One of these patients infected a woman employed to wash the salads and potatoes for the table. During her period of incubation she must have infected these articles of food, as 2 cases developed August 23 and 24, and on the 31st the explosion occurred with 59 cases. By the end of October the epidemic had entirely ceased. A special laboratory was fitted up to determine the presence of typhoid bacilli in the urine and stools of the convalescents. They were found in the urine in 18 per cent. of the total of 98 cases, but only three times in the feces, and in these 3 cases they were also in the urine. The findings were positive only in the first four weeks of convalescence. The bacilli were found from eight to twenty-seven days after defervescence, the average duration being about fifteen days. During the second month of convalescence, therefore, all the patients were free from bacilli with a single exception. This was a patient who suffered from diarrhea constantly during convalescence. The severer the disease the longer the bacilli lingered in the urine. They were always numerous when found at all.

55. **Origin of Tuberculosis.**—[The views advanced by von Behring recently in regard to the origin of tuberculosis have raised a storm of protest on all sides and the medical press is teeming with communications from investigators who have been raking over their material and statistics for data to refute his assertions.] Cornet cites the Prussian official statistics to show the constant progression of the number of cases from the third year upward to the maximum between 60 and 70. He adds that he has personally experimented on between 3,000 and 4,000 animals to determine the mode of infection with tubercle bacilli and allied points. In every instance the portal of entry itself shows signs of the infection or, in any event, the nearest adjacent glands. The exact mode of entrance of the infection can be determined for every individual case from the pathologic anatomic findings except when the general organism is completely involved. The statistics further show that tuberculosis is constantly decreasing in Prussia. The number of lives thus saved amounts to 370,000 since 1889, estimating the deaths that would have occurred if the previous average death rate from tuberculosis had been maintained.

58. **Treatment of Gonorrhea of the Eye.**—Hirsch reports the prompt cure of a threatening case of gonorrheal inflammation of one eye from autoinfection. He commends the technic followed as promising surpassing results for such cases. He made a single subconjunctival injection of a 1/500 solution of hydrargyrum oxycyanate to which a little acoin had been added. There was considerable irritative reaction, but the progress of the process was arrested and three days later the cure was completed by a repetition of the injection.

59. **Principles of Psychotherapy.**—Dubois ascribes to "ankylosis of the brain" the failure of the majority of physicians now growing old in harness to profit by the aids afforded by psychotherapy. He urges on the younger generation the better exploitation of these measures, and protests against the assumption that they belong exclusively to the neurologists and psychiatrists. Psychoneuroses require psychotherapy, and to pay attention to any organ or system merely adds an imaginary organic cause and aggravates the condition. Abnormal physical conditions may exist, but it is better to disregard them until the psychic condition is restored to normal as the mental predisposition is the disease and the others are merely the inciting agent, which may safely be neglected until the psyche is working normally. They will then usually right themselves or will yield readily to treatment. He insists on the necessity of informing the patient that it is the psyche which is diseased and requires treatment. The entire structure of autosuggestion collapses like a card house when the psychoneurosis is cured. He mentions the case of a woman of 40 who had suffered from complete astasia-abasia for ten years with hysteric contractures, etc., dating from the birth of a child. Total hysterectomy had been done to relieve her, without effect; she had taken a number of Weir Mitchell courses, and had strychnin injections for a year, with electricity and massage treatment, but not a trace of improvement. When Dubois saw her she had long been bedridden, with nervous asthenopia, photophobia and constant chilliness. In his half-hour talk with her he succeeded in convincing her that there was no organic reason for her condition and that if she once made up her mind to get up and live like other people she could. In less than a week she was up and about and has been in perfect health since he impressed on her that all she had to do was to transform her idea that she was unable to do certain acts into the idea that she could do them, first clearly setting forth the arguments against the possibility that there was organic disease in the parts affected. Another patient had been treated during eleven years for neuralgia in the pelvis. The pains occurred at every attempt to walk and she had been compelled to live at home like an invalid. She was 35, the wife of a physician, and in blooming health. No indications of nervousness or hysteria could be found except a tendency to be depressed in the morning. He, therefore, explained to her that pain, like other sensations, is at bottom a mental impression. It may be the result of an idea as well as of a physical lesion. He saw her every day and constantly reiterated the necessity of controlling her psychic impressions and thus educate herself out of the idea of pain. Seven weeks of this exclusively psychic treatment—like water dropping on a stone—finally conquered, and there has been no recurrence of the pains during the several months since. In treating such patients the family must be drawn into the conspiracy to preach the necessity for a healthy stoicism and courageous bearing in all things, small and great. The physician to be successful in psychotherapy must be an optimist. The depressing views of the Schopenhauer or Nietzsche school of pessimists must be discarded if one would succeed in curing psychoneuroses. Paralyzing neurasthenia lurks in all the works of these and similar writers. The peace of mind which protects the health of body and psyche rests on a philosophy of life which, notwithstanding the difference in its origins, is common to both the Christian and the free-thinker. What we need is a healthy optimism which shows us life as it is and enables us to be brave and instill courage.

60 **Retention of Chlorids and Salty Sputa in Pneumonia**—Spirig recently encountered a pneumonia patient who complained that his sputa tasted salty. He was tested with other substances and detected a salty taste in them or not, in harmony with the findings by other persons The subjective salty taste was, therefore, an objective reality Spirig suggests that this salty taste of the sputum might be utilized as a means of detecting retention of chlorids in the system in pneumonia and other diseases

61 **Early Diagnosis of Tuberculosis**—Fischer writes from the Beauregard Sanatorium to impress on the profession the necessity of warning the public that the ravages of tuberculosis might be materially reduced if physicians were consulted earlier Any cough that lasts for more than four to six weeks and is accompanied by general depression, loss of weight, etc , should be regarded as a grave sign and medical aid should be sought without further delay He mentions the tenacity and persevering endurance of the Swiss character as a hindrance to this prophylactic measure, relating instances of men keeping doggedly at work for months without consulting any physician, while being rapidly undermined by a pulmonary affection which might have been cured if appropriate measures had been adopted in the beginning

62 **"Eczema Death"**—Feer's comprehensive study of sudden death in children, especially those under treatment for eczema of the scalp, unmistakably establishes a certain connection between the sudden fatality and the eczema He reports 8 such instances that have occurred at the Basle Children's Hospital, and summarizes 22 similar ones found in the literature Von Ranke has seen 16 cases of sudden death in the last ten years preceding 1902 There was no hyperplasia of the thymus in 5 (bronchitis in 3, anemia in 1 and eczema with sudden bronchopneumonia in 2) In 4 other children the thymus was enlarged and there were serious lesions elsewhere In 7 the thymus was enlarged, but there were no other appreciable complications except eczema in 6 He is convinced that there is a close connection between the sudden death and the eczema which Feer corroborates In the total 30 cases of sudden death on record, aside from the lymphatic apparatus, there was nothing to explain the fatality In the 13 cases with careful necropsy pronounced status lymphaticus was noted in more than three fourths, as also in a number of the others For these and other reasons which he enumerates Feer is inclined to regard infantile eczema as a manifestation of a dyscrasia, study of which would elucidate the problem of the status lymphaticus The sudden death of eczema babies usually occurred while the scalp affection was being treated Sometimes it was preceded by high fever, suggesting that the removal of the crusts or the therapeutic applications were responsible without the intervention of a drug intoxication The old dread of 'driving in" the eczema was at first ridiculed by the present generation of physicians, but their experience has compelled them to modify their views Pleurisy, bronchopneumonia or diarrhea have too often followed the cure of eczema of the scalp for the occurrence to be regarded as a mere coincidence With the spontaneous return of the eruption the other affections improved Feer has had no personal experience with this metastasis of eczema, as he calls it, but thinks that it is reasonable to assume its existence and that the sudden eczema deaths are due to metastasis in some vital organ, or at least to the diversion of the exudate with its absorbed or not eliminated toxic substances In some of the cases on record beginning bronchitis and foci in the lungs were found after the sudden death in apparent health He adds that most cases of asthmatic bronchitis in children affect those who were milk crust babies Adenoid vegetations and enlarged glands are also common in such children The dyspnea and cyanosis at the onset of a severe attack of bronchial asthma resemble very much the condition that ushers in the sudden death in the status lymphaticus Any one who has witnessed an "eczema death" is henceforth very cautious in treating a scalp affection He proceeds very gradually and uses the mildest local treatment directing his efforts to improve the general condition Jadassohn stated in the discussion which followed the reading of Feer's paper, that he had never seen a case of "eczema death ' and that he always strove to heal the eczema as promptly as possible, believing that it opened an entrance for infection Demme found tubercle bacilli under the crusts in one instance Hagenbach related a number of cases of sudden death in children, but the status lymphaticus does not explain them all

68 **Medical Prescribing of Alcohol**—Fick argues that all the effects observed from alcohol are in the nature of a paralyzing of the brain cells· The use of alcohol can therefore be depended on when a narcotic action is desired as a sedative, to promote the appetite and against the night sweats of phthisis He admits the efficacy of alcohol in these directions, but doubts the advisability of prescribing it, as the same results can be attained by other means It should be restricted to acute affections and to incurable cases, the latter including the aged The idea that alcohol "strengthens" is erroneous and should be combated There is no doubt that medical prescriptions are responsible for a certain, if small, share of the prevalent alcoholism Naegeli thinks that the paralysis of the vasomotors which follows the use of alcohol is a direct contraindication to employing it in acute infectious diseases, as one of the greatest dangers in this condition is the already existent vasomotor paralysis, which is only aggravated by the alcohol The statistics of the London Temperance Hospital do not show that the death rate is any higher in the absence of alcohol, but rather the reverse Fick never gives alcohol to any patient before or after an operation, and when possible he insists on its non use during the few weeks beforehand In summing up his views on alcohol he cited the famous report of the commission appointed by the English government to study the subject of opium in India Certain prominent physicians and government officials testified in favor of opium as a stimulant, euphoricum and benefit to society!

72 **Nursing Bottle to Arrest Coughing.**—The sipping of fluid will frequently arrest coughing, and Rahn recommends the use of an ordinary nursing bottle to hold the fluid when it is needed by a reclining subject The action of sucking the nipple tends to inhibit the coughing reflex Water, mineral water or any decoction may be used in the bottle to sip in small amounts at any time, night or day, without the necessity for rising or fear of spilling any of the fluid

73 **Hutchinson's Teeth in Inherited Syphilis**—Moncorvo observed typical malformation of the upper and lower incisors in 6 out of 8 cases, while in 2 the lesion was limited to atrophy of the upper incisors In one of the cases there was also a notch in a lower canine tooth

74 **Prophylaxis of Yellow Fever.**—Ribas concludes this detailed analysis of his experiences as director of the public health service at San Paulo with the statement that no epidemic ever occurred where the stegomyia was not prevalent He also mentions that the meteorological conditions affect the

development of an epidemic, not only by favoring the proliferation of the mosquitoes, but also the proliferation of the pathogenic micro-organism inside it.

78. **Prophylaxis of Yellow Fever.**—Pereira is professor of general medicine at Bahia, and argues to prove that yellow fever is an exotic infection in Brazil, and also that it may be transmitted by insects other than the stegomyia. Consequently, measures against the latter should be supplemented by disinfection of the dwelling and of contaminated objects. He urges compulsory disinfection of incoming ships with the Clayton apparatus as a means of preventing the importation of all kinds of pestilential and exotic affections as well as of yellow fever.

80. **Cold Compresses to the Thorax in Bronchopneumonia in Children.**—Pinto is an advocate of frequently renewed, cold, wet compresses applied to the thorax in this affection. The respiration becomes deeper and slower from the moment the cold is applied. They induce an extensive and salutary revulsion over the skin of the thorax, reducing the fever, regulating the pulse, soothing the nervous symptoms, agitation, insomnia, etc., and clearing out the organism by the extensive diuresis induced. He refrains from medication as a rule.

82. **Diazo Reaction in Smallpox in Children.**—Figueira found the diazo reaction positive in 24 children with smallpox, the ages ranging from 34 days to 20 years. It was found from the second day into convalescence, in both mild and severe forms, simple or complicated, with or without fever, and under various methods of treatment. Another child whose varicella was mistaken for smallpox was sent to the smallpox hospital and the absence of the diazo reaction was one of the points that cleared up the diagnosis. In measles he found the diazo contradictory, distinct in 2, but negative in 5. It was also absent in mumps.

83. **Remarkable Fecundity.**—Machado reports the case of a woman of 38, married seventeen years, who has had twenty-four children in eighteen pregnancies. The ninth delivery was an induced abortion about the fifth month, and five fetuses were expelled. This was followed by seven other abortions induced about the fourth or fifth month. The last delivery resulted in the birth of healthy twins. She is a tall woman, the thyroid gland slightly enlarged, the face somewhat asymmetrical, the glance restless, the pupils dilated. As a child she suffered from hysteria and later from ozena. Her husband died at 50. She is the only survivor of five children. Her mother was an epileptic.

84. **Serum Treatment of Snake Bite.**—The main points of Brazil's communication were mentioned in a report of the Brazilian Medical Congress in 1903. (See page 504 of Vol. XLI.)

87. **Early Sign of Pulmonary Tuberculosis.**—Simoes has encountered invariably in tuberculous subjects and never in others, a cutaneous reflex, which he describes as a rapid elevation of the skin—a lump forming when the thorax is percussed. The phenomenon is the more pronounced the farther advanced the disease, but is unmistakable at all stages. As a rule, he has found the right side most frequently affected in tuberculous men and the left in women. The sign is due, he thinks, to the extra irritability of the peripheral innervation of the thorax in these subjects, causing sudden contracture of the muscular fibers at the point percussed, the contracture lasting several seconds, and forcing the derma above them to bulge out. Sometimes the bulging is accompanied by a slight fibrillary wave running through the subjacent muscle. It differs from other reflexes noted by Ziemssen and others in that the wave runs across instead of lengthwise of the muscle fibers. He percusses with a cylindrical instrument of wood, aluminium or other metal, about 12 cm. long by 6 mm. in diameter, one end rounded and the other tapering, using the rounded end to percuss very sensitive subjects and the tapering end for others. The front or the back of the thorax is tapped with this instrument, or even a common lapis stick. The reflex can be elicited almost anywhere over the thorax in advanced cases, but in the incipient stages it is most pronounced in the infraclavicular fossa below the clavicle.

88. **Electric Treatment of Aneurism.**—The method of treating aneurism of the thoracic aorta by local application of the galvanic current has been extensively exploited by the medical profession in Brazil, and all concur in extolling its superior efficacy. The physicians there proudly claim it as the "Brazilian" method, and it has now a long record of successes in their hands during the last two decades. Modesto Guimaraes was able to demonstrate with an artificial or phantom aneurism, made with blood vessels from the cadaver, that the application of the electricity actually did aid in the formation of a clot and obliteration of the sac, under conditions approximating the natural. The anode is impregnated with a 20 per cent. solution of potassium iodid, or, in the case of syphilitics, with mercuric iodid, to take advantage of the phenomena of cataphoresis. Absolute repose and a milk diet are enforced whenever practicable as important aids in the treatment, but the main point is the application of the galvanic current with large electrodes, the anode fully 8/11 or 11/16 cm., while the negative electrode measures 16/24. The positive pole is applied directly over the aneurism, the negative pole to the back, directly opposite the anode. The current is gradually increased to 30 milliamperes and applied for twenty minutes, after which it is gradually turned off again. The minimum is 20 milliamperes and ten minutes' application, the maximum 50 milliamperes and 30 minutes. The pain subsides almost at once. Nature is aided in the process of repair and improvement is evident in eight days to two months of these daily applications, lengthening the intervals to two days after the pains and the other symptoms have subsided. When a cure is impossible 20 to 60 applications are applied as a palliative measure, and are always beneficial. A complete cure requires about 120 to 150. The subsidence of the tumor can be followed with the eye or by radioscopy. Freitas does not make the applications as long as Britto, preferring 15 to 20 milliamperes for fifteen or twenty minutes only. He describes 6 cases in detail, with the photograph of one patient. As a typical example we cite the case of a woman who had suffered for years from a dilatation of the aorta, in extreme anemia from multiple causes, with dyspnea at the slightest effort and exaggerated pulsation throughout the entire arterial system. She received 130 applications of the galvanic current as described, and during the three years since has been completely free from her previous disturbances. She has spent a season at an altitude of more than 3,000 feet, has passed through an exceptionally severe attack of la grippe, but her heart and vascular system have persisted in fine condition without sign of recurrence of her old troubles, while the local condition of the dilated artery is excellent. These facts demonstrate that she has been absolutely cured. (See also No. 76 above.)

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Commoner Diseases of the Eye. How to Detect and How to Treat Them. For Students of Medicine. With 250 Illustrations, Many of Them Original, of Which 7 are Colored Plates. By Casey A. Wood, C.M., M.D., D.C.L., Professor of Clinical Ophthalmology in the University of Illinois, and Thomas A. Woodruff, M.D., C.M., L.R.C.P. THE SURGICAL TREATMENT OF GOITER.[*]

C. H. MAYO, M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

The statistics of the continental surgeons in reference to goiter has greatly added to the wholesome respect we have held as to their surgical skill. There the various operative methods of affording relief have been advanced to a high state of perfection. Especially is this true in localities in which goiter is endemic, where many surgeons have done hundreds, a few over a thousand, and the great surgeon, Kocher, is well along now in his third thousand of operations for goiter. Their mortality is low, and becomes less with increasing experience. In this country, where the disease is comparatively rare, the greater proportion of operations have been from necessity, and too often were delayed until a fatal result was a not infrequent occurrence. Few operators have had a large experience, and the mortality has been somewhat higher, taken as a whole. than that of continental surgeons; but possibly this difference is not so great for the cases of the same average severity when operated upon.

There are a few points in the development, location, structure and function of the thyroid gland which are so directly associated with the disease and symptoms produced that a brief review of the anatomy of the organ will be of advantage. The thyroid gland consists of three parts—two lateral lobes and an isthmus. Each lateral lobe is about two inches long and pointed at the upper end. The isthmus unites their lower inner portions across the trachea, covering from the first to the fourth tracheal rings. The whole gland weighs from one to one and one-half ounces. In the development of the thyroid gland, the inversion takes place from the pharynx, the superior inversion being at the back of the tongue, and the remains of the nearly closed duct is known as the foramen cecum, while the remainder of the duct usually becomes atrophied to a cord extending through the tongue toward the hyoid bone. In 43 per cent. of cases a so-called middle or pyramidal lobe is present, extending from the upper border of the isthmus toward the hyoid bone. It is in these lines of inversion that the accessory thyroids are more often found. a condition which has been thoroughly described by Dr. Bernays. The gland consists of a number of alveoli of small size and various shapes. It is covered by a delicate connective tissue capsule, in and beneath which, upon the surface of the gland, is the venous plexus. Penetrating the gland in all directions from the capsule are delicate connective tissue layers which form and support the alveoli, and in which are located the lymphatic vessels of the gland. The superior thyroid artery from the external carotid supplies the upper horn, entering the capsule at its apex and anastomosing freely with the vessels of the opposite side and the inferior thyroid artery below. The latter vessel arises from the thyroid axis, and enters the gland on its inner inferior surface next the trachea at a point called the hilus. At this point the vessel and gland are in close relation to the recurrent laryngeal nerve, and it is in the ligation of this artery next to the gland that this nerve is so frequently injured. There is occasionally another artery found called the thyroidima; arising from the aorta or innominate artery, it ascends upon the trachea and enters the isthmus. The veins are the superior and lateral, which enter the internal jugular, and the inferior, which is usually quite large, arising from the venous plexus of the capsule, and from either side they usually unite to enter the left innominate vein.

In disease of the gland, the number of veins may be somewhat increased, but the location is nearly constant. The capsule is extremely thin, but behind it divides into two layers, one inclosing the gland. the other passing behind the pharynx and esophagus. A firm band of connective tissue is also attached on each side of the cricoid cartilage, and becomes blended with the capsule to act as a sling support. This peculiar formation of the capsule explains the dyspnea, from lateral pressure of the trachea, often complained of in enlargement, and also why even large tumors are firmly held to the trachea. In certain types of goiter this capsule becomes greatly thickened. Dysphagia may occasionally be present and at times dysphonia. The nerves are derived from the middle and inferior cervical ganglion of the sympathetic as well as the inferior and the external laryngeal nerves. The gland has no duct, but is well supplied with lymphatics, which Baber has shown are filled with the same semiviscid colloid secretion found in the alveoli of the gland. and it is probable that they act as ducts in carrying the secretion to the circulation by way of the tracheal and cervical glands. This theory of the lymphatic system acting as the carrier of secretion from the ductless glands to the circulation. aids in explaining the etiology of various tumors and retention cysts from their inactivity, as well as thyroidism from oversecretion and absorption. These lymph glands, as well as those of the mediastinum, are early involved in malignant disease of this organ. and contribute largely in rendering operations for the relief of such diseases only palliative or worse.

---

[*] Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver. Dec. 28-29, 1903.

The function of the thyroid is a question still under discussion. We know that children born without a thyroid and those who early lose them by operation or atrophy develop a condition known as cretinism. That those in adult life who in any way lose the function of the gland develop myxedema. Tetany may also develop from arrested function—well-known conditions which it is unnecessary to describe at this time. We know that an excess of activity of the thyroid function develops a condition known as exophthalmic goiter, or Graves' diseases, or Basedow's disease. The symptoms of these are characterized by rapid pulse, goiter, protrusion of the eyeballs, retraction of the upper lid, muscle tremor and nervous symptoms. The main symptom is the tachycardia and muscle tremor, other symptoms and the prominence of any depending upon the patient and the stage of the disease. The various changes in the thyroid, aside from malignant, tubercular, syphilitic or hydatid diseases, are such as might be expected from its structure, namely, atrophy, hypertrophy, cysts, adenomas, fibroid or calcareous degeneration and parenchymatous enlargements. The more common form is the latter enlargement, which is the type of uniform tumor seen in young people. It appears at about the age of sexual activity, and is characterized by an increase in the size and contents of the alveoli. In these cases there is also an increase in the solid elements of the gland. This type of goiter frequently, and we may say usually, responds to medical treatment. In many instances the colloid material is so abundant and the alveoli so large in the long-standing parenchymatous goiters that they are called colloid cystic goiters, and it often occurs that several of the various types may be represented in one tumor.

The conditions which have rendered operation imperative have usually been dyspnea, from compression of the trachea or its displacement, and from retrosternal enlargements. Dysphonia and dysphagia have been important symptoms at times, and in many instances the weight and general nuisance of a large tumor as well as cosmetic reasons.

Acute infections often demand surgical intervention. More recently the symptoms of Graves' disease have placed exophthalmic goiter in this domain of surgery; whether properly or not is a matter still under discussion.

Riverdin, in an analysis of 3,408 cases, placed the mortality from total extirpation at 19 per cent.; from partial extirpation, at 3.5 per cent.; from intraglandular enucleation at 78/100 per cent.; from resection, at 6.6 per cent. Such statistics are but relative, however, as it is probable that the total extirpations were demanded for serious conditions and the intraglandular enucleations were presumably for the encapsulated adenomas. The deaths, when immediate, are from hemorrhage, air embolism, myocarditis, suffocation or the anesthetic. Later deaths are usually from pneumonia, from sepsis, tetany or myxedema.

Of the various methods of attacking thyroid enlargements, Mikulicz has developed the resection of a part of one or both lobes after ligating or compressing the arteries. Ostermayer crushes off a part of the gland and applies mass ligatures. Socin has developed the intraglandular enucleation. Kocher advanced the method of eventeration, or incision of cysts and shelling out their contents, and also the popularized common method of lateral extirpation in its capsule, dividing the isthmus and leaving a portion of the capsule at the side of the trachea to protect the recurrent laryngeal nerve, which he injured more or less in 7 per cent. of his first thousand cases. Paucet and Billroth made massive enucleation within the capsule.

Cysts have been treated by puncture, injection and drainage, but are now usually enucleated. Injections of various solutions into goiters are generally considered nearly as dangerous as radical operative measures, and curiously enough, are more employed by the internist than by the surgeon, who always doubts the true position of the point of an instrument as soon as it is out of sight.

The displacement of a goiter by open incision, allowing it to granulate in the open wound, or exothyropexy, is seldom practiced. Incision of the isthmus for tracheal compression is sometimes employed as a temporary measure, but as a rule the relief is slow to manifest itself and the symptoms early recur. Ligation of three or four of the thyroid arteries is nearly as serious an operation as the removal of part of the gland. These cases seem to be exposed to all the risks, both primary and secondary, as if the gland were attacked directly. The removal of a part of the cervical sympathetic ganglion for the relief of exophthalmic goiter, as advocated by Edwards and popularized by Janesco, has had a fair degree of success. It is barely possible that the destruction of the lymphatic ducts efferent from the thyroid may account for some of the improvement noted. This theory will also explain the favorable reports following the exposure of exophthalmic goiter to the *x*-ray.

During the past fifteen years we have had a large number of parenchymatous goiters, which have been successfully treated, usually by some combined internal and external method. In the same period one hundred and ten patients have been subjected to operation for the relief of some type of thyroid tumor. Of these, thirty-four were for exophthalmic goiter, with six deaths. Two were for carcinoma of the thyroid, with one death on the third day from sudden collapsing of the trachea. The other, whose trachea was involved, required the permanent use of a long canula tracheal tube until death occurred fourteen months later. One case was a large lingual thyroid; two cases presented enlargements of the pyramidal lobe only, and these tumors were apparently separate from the remainder of the gland. The other cases, numbering seventy-one, with one death from pneumonia on the eighth day, presented the various types of adenoma and colloid cystic goiters. In two cases there were large areas of calcareous degeneration. One case was a large cyst with sixteen ounces of fluid, and apparently involved the entire gland. Two colloid cystic goiters were very large, one measuring twenty-two, the other nineteen inches across the tumor from one side of the neck to the other, and resting upon the sternum. In three cases the entire gland was apparently removed, but as this operation was by the enucleation method we considered it probable that there was some active gland tissue within the capsule or an accessory gland present, as there were no symptoms developed which could be attributed to the loss of the gland.

We prefer the Kocher collar incision as giving the most exposure and causing the least scar. This incision crosses the gland in the line of the creases of the neck and extends on one or possibly both sides as far as the posterior border of the sternomastoid muscle. In special cases more space is gained by splitting the lower flap in the center down to the upper border of the sternum. The sterno-hyoid and thyroid muscles can at times be retracted sufficiently to deliver the tumor or portion of the gland to be removed; but if they add any difficulties to the operation we have no hesitation in cutting a part or all of them and reuniting them by suture during the later steps of the operation. There is often some difficulty in determining which is the true capsule, and the incision can be deepened into the tumor until gland tissue or tumor tissue is exposed; the hemorrhage is inconsiderable if the larger vessels are avoided. Inspection of the tumor after its free exposure will indicate the best method of procedure in the operative technic of its removal. If the capsule is thick and nearly the whole gland has disappeared into one rounded mass, we prefer the enucleation method of Socin. as in case of cysts they can be evacuated and the cyst wall removed, and if adenomas or large colloid cysts it is possible that enough gland material will be left to functionate should it be necessary to remove the whole mass. If, as is more often the case, the tumor upon exposure retains the general normal contour of the gland, we extirpate one lobe, usually the right, after the method of Kocher. In case of retrosternal enlargements it is delivered with this lobe if possible. The veins leaving the true capsule laterally are divided and the upper horn dislocated sufficiently to double ligate the superior thyroid artery and vein. The tumor is further dislocated and freed from below with dry gauze dissection until the inferior thyroid artery and veins can be ligated. The isthmus is now crushed with large forceps and ligated or closed by sutures after severing the tumor. If there is any difficulty in raising the lobe from the trachea and region of the recurrent laryngeal nerve, the capsule is incised under the lateral border and allowed to remain, the gland being cleansed from its surface. The wound is now closed by a subcuticular suture, and usually free drainage is employed by separate incision or by the vertical median incision above the sternum.

Exophthalmic goiters are extirpated in the same manner, using greater care in avoiding undue force or compression of the gland in its removal. Our usual rule is to give a hypodermic injection of one-sixth to one-fourth grain of morphia about twenty minutes before operation. as it quiets the general nervousness and aids anesthesia. Unless there is extreme dyspnea or extremely marked exophthalmic symptoms we prefer the drop method of ether anesthesia. In such cases we employ the cutaneous injection of cocain. This method is also used if we lack confidence in the anesthetist. The after-results have been perfect in colloid and adenomatous goiters, with the exception of one case of permanent hoarseness, and a few with this feature lasting but a short time. In operating for malignant disease we found the usual rule to hold good, that the operations were delayed, difficult, palliation short and mortality high.

The exophthalmic cases which recovered from the operation were all benefited within a period of three months,; about 50 per cent. became free from exophthalmic symptoms within from three to six months following the operation. In 25 per cent. the improvement was continuous during a year. In 25 per cent. the improvement was partial, the exophthalmus being slow to disappear. None were made worse who lived, and those in whom death occurred were the most severe types of Graves' disease, especially presenting tachycardia of from 130 to 150. Following the operations upon the thyroid gland, a condition of acute thyroidism is probable during the first twenty-four to forty-eight hours. To a great extent it depends upon the amount of traumatism in the operation. This condition is more noticeable in the exophthalmic cases. It is usually accompanied with from one to four degrees of temperature.

MORE LOCAL AND LESS GENERAL ANESTHESIA IN GYNECOLOGIC OPERATIONS.

J. CLARENCE WEBSTER, M.D.
Professor of Obstetrics and Gynecology in Rush Medical College.
CHICAGO.

General anesthesia is of great value in diagnosing many intrapelvic and intra-abdominal conditions, especially in girls, nervous women and in those with tense or thick abdominal walls. Ether and chloroform are the drugs most frequently employed for this purpose. During recent years I have to a great extent discarded these, using nitrous oxid gas in preference, except in cases in which it is contraindicated. The great advantages of this anesthetic are its rapidity of action, safety and absence of after-sickness. The gas is administered through a Packard inhaler, air being inhaled with it.

In carrying out operative procedures I use nitrous oxid and ether, except where there is some contraindication. in the majority of cases. I have found the Packard inhaler very suitable for the administration. A mixture of nitrous oxid gas and air is first given, and as unconsciousness is developed, ether vapor is gradually forced into the inhaler by means of a rubber bulb attached to the bottle of ether. The nitrous oxid reservoir is then disconnected and a mixture of air and ether continued.

When chloroform is indicated the same inhaler is employed, air being allowed to enter more freely. When the mask of the inhaler does not fit a patient's face closely, anesthesia may not readily be induced, because an excessive amount of air is inhaled. Under these circumstances it is advisable to administer ether by means of an open-top pasteboard cone containing cotton; chloroform may be given by means of an Esmarch inhaler, the drug being carefully dropped on it from a small bottle.

Every operator should carefully supervise the administration of these anesthetics, allowing no more than is necessary to be used. Unless this be done patients will often be subjected to unnecessarily prolonged or reckless anesthesia. In cases in which surgical procedures are to be carried out in the lithotomy posture previous to abdominal section, it is frequently possible to carry out the former, either without a general anesthetic or by local anesthesia.

This is particularly necessary when the plastic operations may be extensive or there is expected to be prolonged abdominal work. Frequently the latter is more complicated than was suspected, and the patient may require to be subjected to the added risk of prolonged narcosis.

In recent years I have considerably extended the sphere of employment of local anesthesia, even in major operative procedures, in cases in which prolonged general anesthesia is not considered advisable, e. g., old age, kidney, pulmonary and cardiac diseases, marked anemia, chronic wasting diseases and sepsis. I recommend the Schleich infiltration method, solution No. 2 being employed.

In making the solution I am accustomed to prepare it twenty minutes before it is used, adding a little formalin to it to lessen the risk of infection.

Various plastic operations on the cervix, vagina and vulva may thus be carried out. The diseased uterus and adnexa may be extirpated. In performing this operation after infiltration of the fornix vaginæ and opening the peritoneal pouches, no further application of the anesthetic may be required in most cases; occasionally, however, when the patient complains it is advisable to infiltrate the broad ligaments before ligating them, since the latter procedure usually causes distress.

In opening the abdomen, the skin may be infiltrated for a distance of four or five inches in the line of the incision to be made. Thereafter, in the majority of cases, I rarely inject any more of the anesthetic solution. Formerly it was my practice to infiltrate the successive layers divided, but I now prefer to make a rapid division of the abdominal wall.

Various operations may be carried out after the abdomen is opened, e. g., removal of diseased tubes and ovaries, shortening of the round ligaments, myomectomy, supravaginal amputation of the uterus, appendectomy, resection of the intestine, etc.

It is important that the patient should be encouraged and cheered by the operator throughout the operation. If a few drops of chloroform be sprinkled from time to time on a mask held over the patient's face a strong suggestive influence is often exerted, the patient believing that she is being deeply anesthetized. Sometimes a patient may become so nervous and excited that her struggles make it impossible to continue the operation until general anesthesia is induced. But even if such a course is pursued, the advantage has been obtained of reducing to a minimum the amount of chloroform or ether which is necessary.

In the last five years I have only once been compelled to have recourse to a general anesthetic, in the case of a very nervous Italian woman. The largest operation I have performed without general anesthesia was an abdominal hysterectomy for the removal of a cystic fibromyoma of the uterus weighing 87 pounds. It was performed in the Presbyterian Hospital, Chicago, Dec. 16, 1902. The abdomen was opened after Schleich infiltration of the skin. After working for an hour, the patient became somewhat restless, and she was allowed to inhale a few drops of chloroform. During the remaining hour and a half this procedure was repeated from time to time, six drams of the drug being used in this way. The patient was conscious throughout the whole operation, and frequently engaged in conversation; no reflexes were abolished.

Recently I have performed vaginal cesarean section in a primipara suffering from severe nephritis, without any general anesthetic. The operation was difficult on account of the undilated condition of the vagina and a hypertrophic elongation of the cervix measuring nearly four inches. The procedure lasted about an hour, and was followed by complete recovery.

In conditions of extreme anemia or sepsis, I am convinced that the abandonment of general anesthesia will greatly diminish the risk to patients. I have thus opened the abdomen in ruptured ectopic gestation where the blood examination showed less than 24 per cent. of hemoglobin. In severe sepsis the tendency to degeneration in cardiac muscle, renal epithelium and other structures should always be remembered as a warning against the use of a general anesthetic.

With regard to the sensibility of the various tissues exposed and handled the following observations have been made:

On dividing the infiltrated portion of the skin no pain is felt if the infiltration has been well carried out. Division of the other tissues of the abdominal wall always causes pain, the parietal peritoneum being usually most sensitive. Suturing or dragging of a portion of the latter is always painful. The separation of adhesions between any structure and the parietes causes pain, except when the adhesions are very slight, whereas the separation of adhesions between viscera or between new growths and viscera very rarely causes distress. The omentum may be ligated, divided or cauterized without pain; when it is pulled downward pain is caused. When the intestines are handled, whether inflamed or normal, no pain is usually produced unless the mesentery be pulled forcibly.

Removal of the vermiform appendix does not usually cause distress. When its mesentery is stretched or when adhesions between it and the parietes are separated the patient usually complains.

Compression of the broad ligaments with forceps or ligature usually causes the patient to complain, as does perforation or division of them. Cauterization, scraping or stitching of the peritoneal surface of the uterus is rarely noticed by the patient, except at the attachment of the round ligaments; she usually complains when the organ is forcibly pulled upward or laterally putting the ligaments on the stretch. Ligation, division or stretching of the round ligaments always causes distress.

The separation of the tubes and ovaries adherent to the wall of the pelvis is always painful, though slight manipulation of these structures when free is apparently painless. When the ovary is firmly squeezed, resected or sutured, some complaint is usually made. Separation of the bladder from the uterus causes little or no distress. Division of the vaginal wall around the cervix in the performance of a hysterectomy always causes some pain. Sponging of the visceral peritoneum with gauze usually causes no distress, whereas the same procedure applied to the parietes causes pain which varies in intensity according to the force applied. The pain felt on the removal of a gauze drain from the abdomen is probably either due to friction against the parietal peritoneum or to traction on a mesentery or the omentum.

Slow flushing of the peritoneal cavity with hot (105 to 108 F.) normal saline solution usually causes slight or no distress. If, however, the abdomen be unduly distended the patient may complain.

My observations made during the last few years are almost entirely in harmony with those recently published by Lennander of Upsala, in an important contribution to our knowledge of the sensibility of the entire abdominal cavity, his chief conclusion being that all pains felt within the abdomen during operations or in disease are to be referred to parts which are innervated by the intercostal lumbar and sacral nerves, i. e., to the diaphragm and abdominal walls, as well as to such organs of which we know with certainty that they are innervated by the nerves in question or are in near relation to them.

100 State Street.

To remove foreign bodies from the ear, dip the end of a camel's hair brush in glue and leave it in position against the body. When dry, after a few hours, pulling on the brush will remove the whole thing.—*Canadian Practitioner.*

THE ULTIMATE RESULTS OF THE BLOODLESS REPLACEMENTS OF CONGENITALLY DISLOCATED HIPS.

JOHN RIDLON, M.D.
CHICAGO.

(Concluded from Page 1016.)

CASES IN THE THIRD GROUP.

The third group consists of the Lorenz cases, and is divided into three subgroups: (*a*), (*b*) and (*c*). He examined in my office and refused to operate on 17 patients, 27 hips, from 7 years (with 2½ inches shortening) to 29 years of age. He recommended operation in 3 other cases that, insofar as I can learn, have not been operated on. He advised operation in a unilateral case of 9 years, the operation to follow preliminary stretching by weight and pulley in bed for some weeks. This case I have since operated on, breaking the neck of the femur (Case 100, Group 4). He refused to operate on a unilateral case, a girl of 8 years, on the ground that replacement was impossible. This case was at once operated on by Dr. John L. Porter and myself, and appears as Case 98, Group 4.

Of these 32 hips, 15 were right and 17 were left. Of the 22 patients, 19 were girls and 3 were boys. One of the cases in which operation was recommended was 2 years old, and all were within the age limit, excepting Case 100 above referred to.

In detail the cases were as follows:

GROUP 3 A.

No.	Sex.	Age.	Hip.	Shortening.
51.	F.	10 yrs	R	
52.	M.	8 yrs	B.	2 in.
53.	F.	11 yrs	L.	
*54.	F.	8 yrs	B.	1½ in
55.	F.	20 yrs	L.	2¾ in
56.	M.	10 yrs	R.	1¾ in
57.	F.	8 yrs.	B.	
58.	F.	9 yrs	L.	
59.	F.	11 yrs	R.	
60.	F.	29 yrs.	B.	3½ in
61.	F.	13 yrs	L	2¼ in
62.	F.	16 yrs	B.	
63.	F.	13 yrs.	B.	
64.	F	9 yrs	L.	
65.	F	12 yrs	R.	2½ in
66.	F.	7 yrs.	B.	2½ in.
†67.	F.	12 yrs	B	4½ in.
68.	F	2 yrs	B	
69.	F.	8 yrs	L	
70.	M.	9 yrs	R.	2 in.
71.	F.	8 yrs.	L	
72	F.	9 yrs	R	

*Same as Case 23. †Same as Case 39

Two of these cases have since been operated on and will be referred to later on; none of the others have answered letters of inquiry as to their condition.

Group 3 (*b*) comprises the cases seen by me that Lorenz operated on. There were 22 patients, with 26 dislocated hips; 13 were right and 13 were left. Three of the patients were boys and 19 were girls. Their ages ran from 2 to 12 years. The shortening was from three-fourths of an inch to 2 inches. The results in these 26 hips were 12 anterior transpositions, 4 supracotyloid displacements, 7 failures, 1 apparent replacement and 2 perfect replacements. It is more than likely that some of the anterior transpositions will ultimately become supracotyloid. The accidents were: One torn perineum, one paralysis, one fracture of the neck of the femur, and one fracture of the shaft of the femur.

GROUP 3, B.

Case 73.—Female, age 6 years; right hip; shortening 1 inch. Same as Case 33. Operated on Oct. 12, 1902. Result said by Lorenz to be anterior transposition or "apposition."

Case 74.—Male, age 3 years; left hip; shortening ¾ of an inch. Apparent replacement immediately after operation. Parents told by Lorenz on removal of splint that replacement was perfect. Feb. 1, 1904, Dr. J. L. Porter found ½ an inch shortening and supracotyloid dislocation. See Fig. 6.

Case 75.—Female, age 11 years; left hip; shortening 2 inches. Same as Case 22. Failure. Improved position.

Case 76.—Female, age 8 years; right hip; shortening, 2 inches. Apparent replacement. Found anterior on removal of splint. Perineum torn from vagina into rectum at time of operation. Repaired by my house surgeon, and healed kindly.

Case 77.—Female, age 7 years; right hip; shortening, 1¾ inches. Professor Lorenz tried to effect replacement and gave up, saying: "It is not possible." At the suggestion of Dr. Ashley, who was assisting, I made the attempt and very soon effected a replacement. Lorenz then took the leg and made further stretching. There was extensive ecchymosis and a large hematoma following the operation. On removal of the splint the head was in anterior transposition, where it has remained. The right leg is one inch short. The femoral head shows prominently in the groin 1¾ inches below and ½ an inch to the inner side of the anterior superior spine of the ilium. The foot is rotated out 45 degrees in standing and 90 degrees when lying. There is a hollow about 2 inches across and about ¾ of an inch deep at the point where the adductors were torn from their upper attachment. The buttock is flattened. The abducted position in which the leg is held compensates for the real shortening, and the child walks very well. (Fig. 7.)

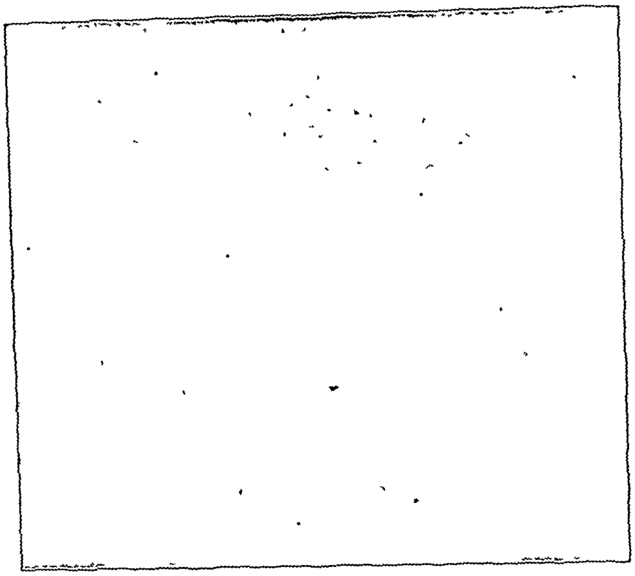

Fig. 6.—Case 74 Operated on by Lorenz. Apparent replacement. Became supracotyloid, apparently in much the same position as before operation. Skiagram Feb. 1, 1904.

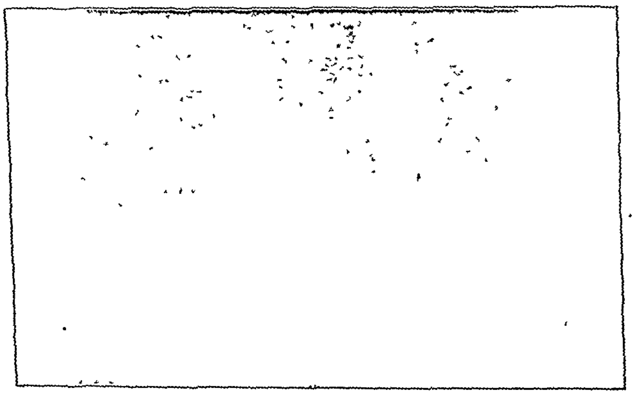

Fig. 7.—Case 77, Group 3 b, or Case 99, Group 4 Operation attempted by Lorenz, who gave it up as "impossible." Replacement made by Ridlon; limb afterward manipulated by Lorenz. Result: Anterior transposition. Head can be seen and felt in the groin. There is one inch shortening. Outward rotation deformity 45 degrees standing, 90 degrees lying. The skiagram shows the head apparently in an enlarged acetabulum, but it really lies below the anterior superior spine of the ilium. Skiagram made Feb. 19, 1904.

Case 78.—Female, age 2 years; left hip; shortening. I examined the case six weeks after the operation. There was apparent replacement. The case can not be traced. She is believed to have entered the hospital under an assumed name.

Case 79.—Female, age 10 years; left hip; shortening, 2 inches. Apparent replacement. Found anterior on removal of splint. Figure 8, from a photograph made at the time, shows the other hip also dislocated; the hip operated on being in anterior transposition.

Case 80.—Female, age 5 years; right hip; shortening 1¼ inches. Apparent replacement. Found anterior on removal of splint.

Case 81.—Male, age 9 years; right hip; shortening 1¼ inches. Femoral head could be felt in the groin two weeks after the operation. Does not answer request for examination and *x*-ray.

Case 82.—Female, age 8 years; left hip. Failed to replace, or transpose, after supreme efforts and prolonged traction by three powerful men. Plaster splint put on leg with abduction. Severe pain for some weeks, followed by paralysis.

Case 83.—Female, age 6 years; left hip; shortening ¾ of an inch. Same as Case 16. Dr. Lorenz told the father that the result was an anterior transposition.

Case 84.—Female, age 9 years; right hip. Head found prominent in the groin on removal of plaster splint and limb rotated out beyond 90 degrees. Dr. D. N. Loose reported it to me as a thyroid dislocation with 1½ inches lengthening. On examination I regarded it as an extreme transposition.

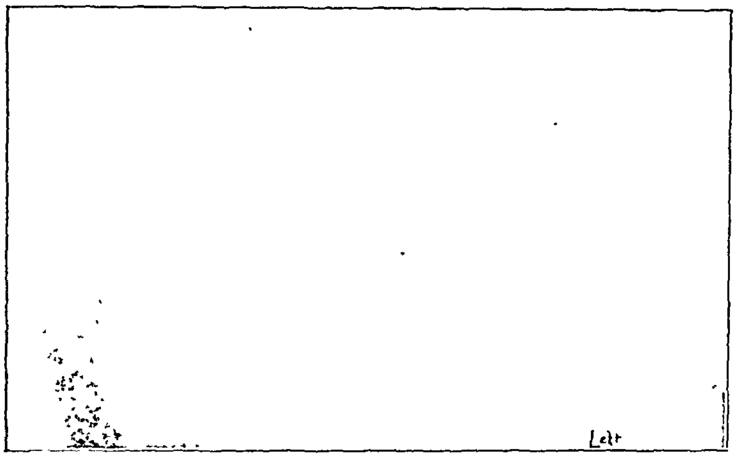

Fig. 8.—Case 79. Left hip operated on by Lorenz. Skiagram on removal of splint shows left hip in anterior transposition and right hip (not operated on) also dislocated.

Case 85.—Female, age 9 years; right hip. Splint removed by Lorenz at end of six months. Mother told that replacement was perfect. Now, Feb. 12, 1904, the limb is one inch short, and the head can be felt above and anterior to the acetabulum. Abduction compensates for the real shortening and the patient walks with scarcely a limp.

Case 86.—Female, age 8 years; left hip. Operated on Oct. 20, 1902. Lorenz broke the femur below the trochanters, and failed to replace the hip.

Case 87.—Female, age 7 years; both hips. Same as Case 48. Operation by me had been a failure. Lorenz apparently replaced the left hip, but fractured the femoral neck on the right side; the head could be felt separate from the neck under the gluteal muscles. Both legs were put up in plaster in the extremely abducted position. On removal of the splint the position was as shown in the skiagram, the left hip anterior and the head of the right showing indistinctly on the dorsum of the ilium.

Case 88.—Female, age 4 years; left hip. On removal of the splint the head was found in extreme anterior transposition.

Case 89.—Female, age 12 years; right hip; shortening 2 inches. Failed to replace or transpose. Splint put on in improved position.

Case 90.—Male, age 5 years; both hips. Apparent replacement of both hips. On removal of splint the right was found anterior, and the left apparently in place.

Case 91.—Female, age 3 years; right hip; shortening ¾ of an inch. Same as Case 18. (See Figs. 1 and 2.) Apparent replacement. Found anterior on removal of splint and has now become supracotyloid, with ½ an inch shortening.

Case 92.—Female, age 4 years; both hips. Apparent replacement of both hips. When I examined the case ten months after the operation I found the first splint had been removed and another put on with extreme abduction reduced about one-half. Both femoral heads could be felt under the splint distinctly anterior.

Case 93.—Female, age 5 years; both hips. Left hip apparently replaced; but Lorenz failed to replace the right, and this hip was not put in a splint. On removal of the splint from the left hip anterior transposition was found, which now has become supracotyloid. There is about ¾ of an inch shortening.

Case 94.—Female, age 2 years; left hip. Apparent replacement. Found apparently perfect on removal of the splint. (Fig. 9.)

Beside these there was another case, E. B.. 3 years old, that was operated on at Mercy Hospital, Oct. 25, 1902, by Professor Lorenz. The case was reported in the newspapers as a case of congenital dislocation of the hip, and so the mother understood the diagnosis to be. It was, however, a case of hip disease, without dislocation, that was first exam'ned by me at the Home for Destitute Crippled Children, July 11, 1902. Lorenz' plaster splint was removed Jan. 31, 1903.

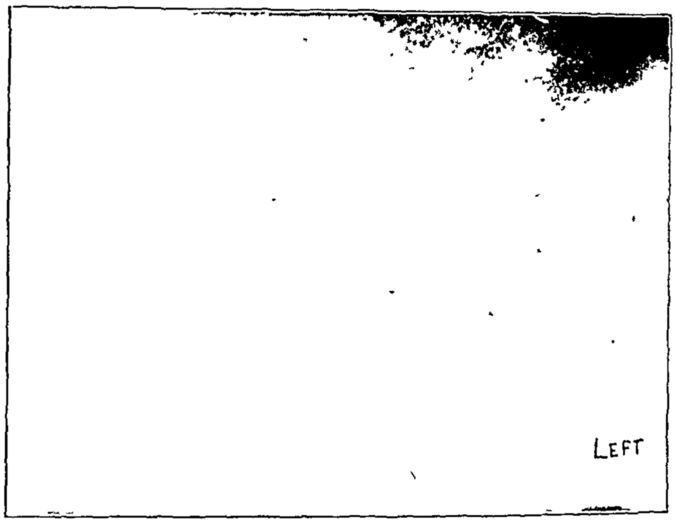

Fig. 9.—Case 94. Operated on by Lorenz. Skiagram on removal of splint. Perfect replacement. Has not been examined since.

The house surgeon at Mercy Hospital made the following report to me from the hospital records:

Oct. 25, 1902. Hip was stretched by working the adductors and pulling in straight line to the body. Head was brought into acetabulum. Body was next secured in his apparatus, collar about ankle, and leg was brought in over-extension, support being in small of back. Enough traction was used to keep head in acetabulum. Plaster cast was applied in this position. Cast to remain on 3 months, and according to findings another may be put on.

Group 3 (*c*) comprises the cases operated on by Lorenz, in which I have had no personal responsibility, but about which I have been able to learn the facts. Dr. T. A. Davis, Chicago, permits me to report the following case:

Case 95.—Female, age 6 years; left hip. (Fig. 10.) Operated on by Prof. Lorenz at the College of Physicians and Surgeons Oct. 31, 1902. The plaster splint put on at the time of the operation was left on seven months, as was directed; and two other splints were put on by Dr. Davis; altogether she was in plaster about eleven months. Dr. Davis believed the ultimate result to be a complete relapse into the position previous to the operation. Feb. 22, 1904, Dr. J. L. Porter examined and radiographed this case. (Fig. 11.) He reports: The left leg is ⅞ of an inch short; outward rotation when lying, 90 degrees; when standing, 45 degrees; head can be felt in groin just external to femoral vessels one inch below anterior superior spine; walks with a marked limp. The parents think she is improved over former condition.

Dr. J. L. Porter, Chicago, permits me to report the two following cases:

CASE 96.—Female, age 2 years; left hip. Operated on by Lorenz Oct. 16, 1902. The splint applied at the time of the operation was left on six months. When taken off the leg was brought down half way and replaced by another by Dr. Porter. This was worn two months. Then another was put on with the leg nearly straight. At both sittings the head was felt in the acetabulum, so far as palpation and measurements could determine. Figure 12 shows the condition before operation Feb. 20, 1904, I examined this case. The limb is ¾ of an inch short, outward rotation about 45 degrees, the head of the femur can be felt between the anterior superior spine and the upper border of the acetabulum, with the top of the head about on a level with the anterior superior spine. Walks with a marked limp, and the mother thinks the gait is growing worse.

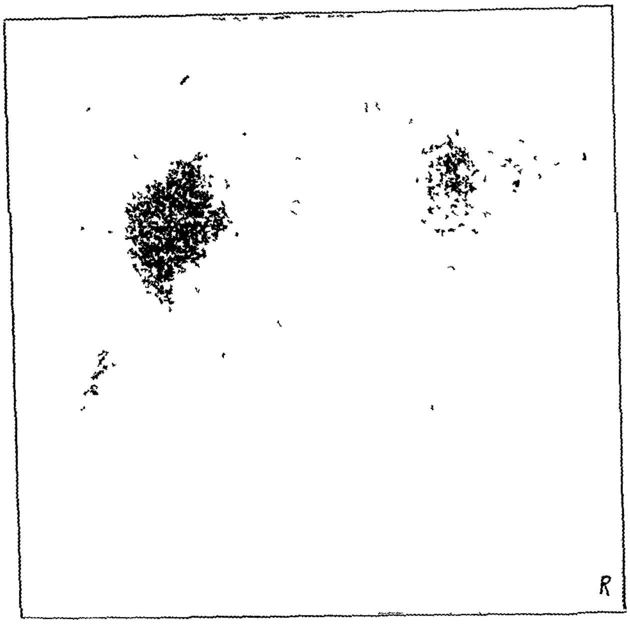

Fig. 10.—Case 95. No. 1. Before operation by Lorenz. See Figure 11.

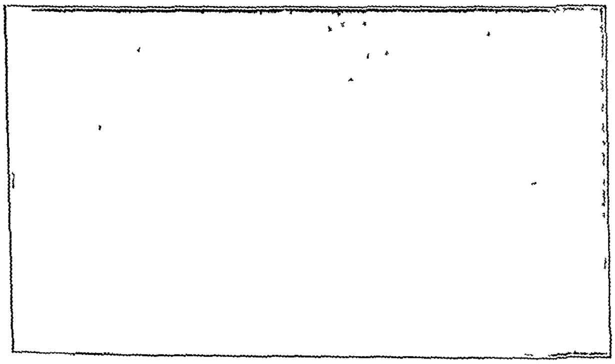

Fig. 11.—Case 95. No. 2. Skiagram Feb. 22, 1904. Compared with Figure 10 shows complete relapse. There is a supracotyloid dislocation on examination.

CASE 97.—Female, age 5 years; right hip. Operated on by Lorenz Oct. 16, 1902. Dr. Porter had made two previous replacements without extensive tearing of the adductor muscles and both times it had relapsed. The splint put on at the operation was removed at the end of six months; the second, put on by Porter, was removed at the end of two months, and a third about the middle of July, 1903. The head of the femur could be felt in the groin at each sitting. The leg was brought entirely down by July. Feb. 20, 1904, I examined this case. The limb is one inch short; it is possible to passively flex the limb in the anteroposterior plane only about 20 degrees, but in the lateral plane it can be carried to a right angle; the outward rotation standing is 45 degrees, and lying 90 degrees; the head can be felt and seen in the groin below and internal to the anterior superior spine, exactly under (posterior to) the femoral vessels. Walks with a marked limp; mother does not notice any change in gait.

Of these 29 hips operated on by Lorenz, there are two perfect replacements (as shown by the skiagram, but their condition has not been observed six months after the removal of the splints); one apparent replacement (which may prove permanent); six supracotyloid displacements; thirteen anterior transpositions and seven failures.

It would not be fair to place these figures in comparison with the results of other operators. To any one witnessing Lorenz' work in this country, it was obvious that he could not do his best work before a large and critical audience. The after-treatment was in most instances not in his hands, or in those of his assistant, and some allowance must be made for that. On the other hand, insofar as my observation goes, those cases that have been wholly under his personal care and the personal care of his assistant, do not show better results than the others, and the two cases that I have reported as perfect have not been seen by Lorenz since they were operated on.

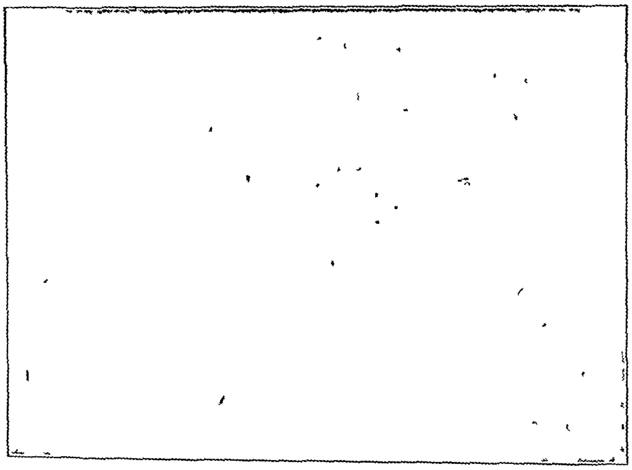

Fig. 12.—Case 96. Operated on by Lorenz Oct. 16, 1902. Skiagram by Dr. John L. Porter Oct. 13, 1902.

Oschner[3] says of Lorenz' results: "In 212 carefully observed cases treated before Jan. 1, 1899. Lorenz reports 108 anatomically and functionally perfect results; 102 anatomically imperfect, but functionally good." Comparing these figures with all "carefully observed" results of his work in this country, I am forced to the conclusion that the difference requires some explanation that I am not able to give.

As I have already said, I believe this is the best operation for all congenitally dislocated hips, and the only operation to be considered in bilateral dislocation, but I think the results will be about what has been shown in these 29 hips, namely, about 10 per cent. perfectly stable anatomically perfect replacements; about 50 per cent. to 60 per cent. of anterior transpositions or "appositions," and supracotyloid displacements, "good results," and about 20 per cent. to 30 per cent. failures. With such results as these I think we must be satisfied.

---

CASES IN FOURTH GROUP.

Group 4 consists of those cases that have been under my observation and have been operated on by me since Oct. 12, 1902, and are not included in either of the other groups.

There were 43 patients, with 53 dislocated hips; 25 were right and 28 left. Three of the patients were boys and 40 were girls. Their ages ran from 17 months to 13 years for those operated on, with one 21 years old that was rejected. The shortening was from one-half inch to 3½ inches for those operated on.

The results were: Seven anterior transpositions; 4 supracotyloid displacements; 5 failures; 4 apparent replacements on removal of the splint, the condition of which can not be positively verified at this time; 6 perfect replacements; 2 (in the patient 21 years old) were rejected; 4 refused operation; 6 are waiting for operation; and 15 were apparently replaced at the operation and are still in their plaster splints.

It is probable that some of the 4 apparent replacements may become anterior transpositions or suprocotyloid displacements; and it is possible that some of the supracotyloid displacements may relapse into posterior dislocations.

The accidents were the fracture of the neck of the femur in two girls of 9 and 10 years, respectively.

Group 4.

Case 98.—Female, age 8 years; left hip. Same as Case 71. Rejected by Lorenz. Operated on by Dr. J. L. Porter and myself. Apparent replacement. Found anterior on removal of splint. Again replaced and abduction reduced. Found supracotyloid on removal of splint.

Case 99.—Female, age 7 years; right hip. Same as Case 77. (Fig. 7.) Apparent replacement. Found anterior on removal of splint.

Case 100.—Female, age 9 years; right hip. Same as Case 72. Neck of femur fractured and head not replaced. Walks well; abduction compensating for the real shortening. Has little motion at the joint.

Case 101.—Female, age 10 years; right hip. Fracture of neck of femur. Now abducted 45 degrees; very little motion.

Case 102.—Female, age 3 years; left hip; shortening ½ of an inch. Perfect replacement. This child also had congenital talipes calcaneus and a congenital kyphosis. On removal of the splint there was apparently perfect replacement. At the end of six months the child began to complain of cramps in the leg; flexion at the joint was restricted and the femoral head could be felt in front. Under massage and passive motion the cramps ceased, the head disappeared and motion returned. The condition is now normal.

Case 103.—Male, age 4 years; both hips. Apparent replacement. Femoral heads found anterior on removal of splint.

Case 104.—Female, age 13 years; left hip. Patient had spastic paralysis and had never walked. Fragile bones were feared and the adductors and long flexors were tenotomised before replacement was attempted. Replacement was made without difficulty and remained permanent.

Case 105.—Female, age 5 years; left hip. Perfect replacement.

Case 106.—Female, age 8 years; left hip. Apparent replacement. Has not been seen six months after removal of splint.

Case 107.—Female, age 3 years; right hip. Apparent replacement. Has not been seen six months after removal of splint.

Case 108.—Female, age 2 years; left hip. Perfect replacement on removal of splint. Dr. J. C. Sexton, Rushville, Ind., reports that replacement has remained perfect.

Case 109.—Female, age 6 years; left hip; shortening 1½ inches. Apparent replacement. Found anterior on removal of splint. The child had had in infancy a congenital talipes equinovarus and genu-recurvatum on this same side.

Case 110.—Female, age 17 months, left hip. Apparent replacement. Found supracotyloid on removal of splint. Abduction compensates one inch shortening, and child walks with scarcely a limp.

Case 111.—Female, age 3 years; both hips. Apparent replacement on removal of splint. Skiagram showed slight supracotyloid displacement. Still under treatment, but it is expected that the result will be supracotyloid displacement.

Case 112.—Female, age 9 years; both hips; shortening 3 inches. Was a large, strong girl. Six weeks' preliminary traction was made. Replacement was made without difficulty but before the plaster splint was fully on it was found that there was little or no circulation below the knees and no pulse at the ankles. The plaster splint was cut off and the hips redislocated. Circulation soon returned. The parents refused to permit further treatment.

Case 113.—Female, age 5 years; right hip; shortening 1½ inches. Apparent replacement. Found anterior on removal of splint. Again replaced and put up with abduction and flexion half reduced. Dr. Clifton Scott, Des Moines, reports perfect result ten months after the operation.

Case 114.—Female, age 4 years; both hips. The hips were dislocated anteriorly. There also was congenital talipes equinovarus, knees flexed 45 degrees with little motion and no patellæ, clubbed hands, elbows flexed 30 degrees and having little motion, arms webbed to the body one-third of the way to the elbows and having little motion in abduction. The hips have not been operated on.

Case 115.—Female, age 3 years; both hips. This case was precisely like the last, No. 114, except that the hands and elbows were normal.

Case 116.—Female, age 4 years; left hip. Apparent replacement on removal of splint. Can not be traced.

Case 117.—Female, age 10 years; right hip; shortening, 1½ inches. Still under treatment.

Case 118.—Female, age 7 years; left hip; shortening 1¾ inches. Failed to replace. Put up abducted to improve position. Walks fairly well.

Case 119.—Female, age 8 years; right hip. Apparent replacement. Found anterior on removal of splint.

Case 120.—Female, age 2 years; left hip; shortening 1 inch. Perfect replacement.

Case 121.—Female, age 2 years; left hip. Apparently in place on removal of splint. Not seen since. Mother reports child "doing well."

Case 122.—Female, age 2 years; right hip. Refused operation.

Case 123.—Female, age 6 years; both hips. Apparent replacement. On removal of splint the left hip was in place, and the right was anterior.

Case 124.—Female, age 21 years; both hips. Rejected.

Case 125.—Male, age 4 years; right hip; shortening 1⅛ inches. Apparent replacement. Still under treatment.

Case 126.—Female, age 10 years; left hip; shortening 3½ inches. Apparent replacement. Still under treatment. These last two cases are brother and sister.

Case 127.—Female, age 2 years; left hip; shortening 1 inch. Apparent replacement. Still under treatment.

Case 128.—Female, age 8 years; left hip; shortening 2 inches. Apparent replacement. Still under treatment.

Case 129.—Female, age 13 years; right hip; shortening 2½ inches. Preliminary traction. Apparent replacement. Still under treatment. A skiagram shows supracotyloid dislocation, a flattened head and a short neck. This is the oldest case I have operated on.

Case 130.—Female, age 5 years; right hip; shortening 1⅛ inches. Apparent replacement. Still under treatment.

Case 131.—Female, age 3 years; both hips. Apparent replacement. Still under treatment.

Case 132.—Male, age 6 years; right hip. Apparent replacement. Still under treatment.

Case 133.—Female, age 3 years; left hip; shortening ⅞ of an inch. Apparent replacement. Still under treatment.

Case 134.—Female, age 2 years; both hips. Refused treatment.

Case 135.—Female, age 6 years; right hip. Apparent replacement. Still under treatment.

Case 136.—Female, age 18 months; left hip. Apparent replacement. Still under treatment.

Case 137.—Female, age 11 years; right hip. Apparent replacement. Still under treatment.

Case 138.—Female, age 9 years; both hips; shortening, left 1 inch, right 1¾ inches. Apparent replacement. Still under treatment.

Case 139.—Female, age 3 years; right hip; shortening 1 inch. Supracotyloid dislocation. Not yet operated on.

Case 140.—Female, age 4 years; left hip; shortening ¾ of an inch. Refused operation. Also has bilateral genu-recurvatum.

Deducting 10 duplicated cases, with 13 hips (from the total, 140 patients, with 172 hips), leaves 130 patients, with 159 dislocated hips. Of these 159 dislocated hips, 94 have been operated on. The results in several are not final, but only 10 can be asserted to be perfect anatomic replacements. About these I have no doubt. How many of the 14 that were apparently in place when the splints were removed, but have not been radiographed or examined six months later, will prove to be permanent, is, of course, a matter of opinion. Some are likely to prove permanent; some are likely to become anterior or supracotyloid, and some may relapse, but none of the dislocations originally dorsal have been demonstrated to have relapsed when the adductor muscles have been freely torn.

How many of the 33 anterior transpositions and supracotyloid displacements will relapse into the dorsal position is also a matter of opinion, but as I have already said none have been demonstrated to have done so. How many of the 15 still in plaster splints will be perfect, anterior or supracotyloid is also a matter of opinion. but I feel sure none will relapse into their former position on the dorsum of the ilium.

If, then, we are satisfied to call an anterior transposition and a supracotyloid displacement, where the shortening is fully compensated by the abduction, if we may call these "good results," and I think we may, we have 61 "good results" and 10 perfect replacements out of 94 hips operated on.

There were 17 failures to replace (7 by Lorenz and 10 by me) and 5 relapses (all mine and before Lorenz came). Lorenz operated on 2 of my relapsed hips and on 3 that I failed to replace. He failed in 2 of the latter, breaking the femoral neck in 1, and has anterior transpositions in the 3 other cases.

Lorenz' teachings have led me to assume that he expects, in some instances, to obtain perfect anatomic replacement in some cases where the femoral head is in anterior transposition, or "apposition," when the splint is removed. I doubt very much if this will be found to be possible. At any rate, it has not been demonstrated, nor do I believe that any of supracotyloid displacements will, by any bloodless procedure, be made perfect replacements. When anterior transposition results it appears to be due to too freely tearing the tissues in front of the joint; when these are healed they are not sufficiently strong to retain the head in the acetabulum if it is again replaced. When supracotyloid displacement results it appears to be due. as shown by the skiagrams, to a deficient upper lip to the acetabulum, or what Lorenz calls a "saucer-shaped" acetabulum, in contradistinction to a "cup-shaped" socket.

In cases where the adductors are not freely torn and the anterior tissues not overstretched, relapse into the dorsal position may occur. Then replacement may be made, again and again, with a reasonable prospect of success. This was demonstrated in Ochsner's celebrated case, where three replacements were made before a perfect and permanent replacement was effected.

My experience leads me to believe that if a femoral head is not actually well buried in the acetabulum, and shown to be so by the *x*-ray, when the splint is removed, it is very doubtful if a permanent replacement will ever result; the result is pretty sure to be an anterior transposition, a supracotyloid displacement or a relapse into its former position. And I am inclined to think that a replacement that can be displaced by bringing the limb down beside its fellow, and this is the condition practically always present, is not really replaced; but that it simply rests more or less deeply within the contracted cotyloid ring; that when the head readily becomes displaced it does not thereby demonstrate a shallow acetabulum, but simply a contracted cotyloid ring. It certainly indicates that a perfect anatomic replacement is not likely to be the result, but that it is not necessarily impossible.

Dr. G. G. Davis, Philadelphia, in a paper[4] read before the *American Orthopedic Association*, last June (1903), says: "To obtain a perfect result it is necessary, first, that a well-formed acetabulum be present and that the femoral head be likewise well formed and set on the neck and shaft in its proper position and direction. Also that the ligaments be so placed as to allow of the proper replacement of the head back into the acetabulum." With this proposition I fully agree.

In considering these cases we learn that the operative age in bilateral congenital displacements is at least a year or two years less than in unilateral cases; that the age of choice is from three to five years; that occasionally a bilateral case as old as eight or nine is possible, and a unilateral case as old as eleven or twelve; that age, *per se*, is not so much to be relied on as the amount of shortening and the rigidity; and that the results of apparent replacements in bilateral cases is much less certain; that is to say, certain of remaining in place than in unilateral cases.

We learn that anterior transposition frequently follows too violent operative measures in reduction; and that retraction (structural shortening) of the posterior muscles of the hip, as pointed out by Redard of Paris, during the period of retention in the extremely abducted position, is the cause of the outward rotation of the limb, or the inability of the patient to rotate the limb inward, and is a condition very difficult, often impossible to correct; and the generous tearing of the adductors, as practiced by Lorenz, adds to this misfortune.

On the other hand, in those cases where the final result is a supracotyloid displacement, it appears that the adductors show little or no tendency to recontract, and the limb is held sufficiently abducted to greatly, and in many instance completely, compensate for the actual shortening from 1 to 1½ inches, and the patient walks with little or no limp. Also, in some of the cases where replacement, anterior transposition or supracotyloid displacement has not been possible by the operation, much the same functional result may be had by freely tearing the adductors and subsequently maintaining the limb in extreme abduction for some months.

---

[4] Amer. Med., Aug. 29, 1903.

In operating one is called on to choose between a possible relapse into dorsal dislocation, and the passing of the head into anterior transposition, in case perfect replacement is not obtained. If one does not tear the adductors freely, relapse into dorsal dislocation may be the result; if one tears them too freely, anterior transposition may be the result; and if one chooses the middle ground, supracotyloid displacement may be the result. A good skiagram will be of immense assistance in helping one to a choice between not tearing and tearing freely, and in the absence of a skiagram one may judge fairly accurately by the ease with which displacement results when the limb is adducted.

I am inclined to the opinion, though it has not been proved, that other congenital defects in the child, such as clubfoot, genu-recurvatum, absent patellæ, clubbed hands, defects of the elbows and shoulders, congenital kyphosis, rupture, etc., in the patient, and congenital defects in the parents (the father of one of my patients had congenital absence of the leg), all render a perfect replacement less probable.

There can be no doubt that subcutaneous division of the long-thigh muscles would make reposition much easier in all cases and possible in some otherwise impossible cases. But to a strong and patient operator the shortened muscles do not form the chief obstacle—it is the shortened nerves and blood vessels which, when put on the stretch, give paralysis and obstructed circulation. This is illustrated by Case 112, where replacement, after preliminary weight-and-pulley stretching in bed, was easily effected in a strong-muscled girl of 9 years with three inches shortening. The circulation was cut off and the hips had to be redislocated.

On the other hand, in Case 129, a girl of 13 years, the hip was replaced after preliminary stretching and the circulation remained good, but the skiagram shows the upward displacement not great, though the shortening as shown by measurement was 2½ inches. Some of this shortening was unquestionably due to the shortening of the femoral head and neck.

Paralysis, which is one of the possible accidents, appears to me to be due to a too severe longitudinal stretching at the time of the operation.

Tearing of the perineum need not result if a rubber pad is placed beneath the sheet that is passed between the legs and fastened to the table to give counter-traction.

In Case 79 a skiagram (Fig. 9) was made when the splint was removed, and shows anterior transposition of the operated hip and an upward displacement of the hip not operated on. I can not believe that Professor Lorenz could have overlooked this dislocation, and can only assume that it became dislocated during the period of walking with the pelvis tilted and the leg adducted to accommodate the leg in the plaster splint.

Fracture of the shaft of the femur, which happened in one of Lorenz' cases, and fracture of the neck of the femur, which happened once under Lorenz' operation, and twice under mine, seems to be due to lack of patient and deliberate manipulation on the part of the operator. Fracture of the shaft should be put up in plaster with the limb fully extended, as Lorenz did in his case. Figure 10 shows how good the result was. In fracture of the neck, I believe the limb should be put in extreme abduction for three or four weeks and then gradually brought down beside its fellow while the plaster splinting is continued. By this method one of my cases gave a good result, while Lorenz' case and my second case, treated for six or eight months in right-angled abduction, gave a permanent abduction deformity which promises the need of another operation.

Note:—The discussion on this paper will be found in Society Proceedings in this issue, in the report of the New York Academy of Medicine.

THE FIRST USE OF ETHER AS AN ANESTHETIC.

AT THE BATTLE OF THE WILDERNESS IN THE CIVIL WAR.*

W. T. G. MORTON, M.D.
BOSTON.

On previous occasions it had been my privilege to visit battlefields, and there to administer the pain-destroying agent which it pleased God to make me the human agent to introduce for the benefit of suffering humanity. How little did I think, however, when originally experimenting with the properties of sulphuric ether on my own person, that I should ever successfully administer it to hundreds in one day, and thus prevent an amount of agony fearful to contemplate.

When the news of the commencement of the Battle of the Wilderness reached Washington, the surgeon general at once said that there would be work for his corps, and for such volunteer surgeons as could be obtained. Previously notified that a requisition would be made for my professional services, I was a "minute man," and left with the first party, taking a steamer for the landing-place called Belle Plain. . . .

I was awakened about daybreak by the clatter of hoofs and rattling of wheels. Peeping out from under my blanket I saw a four-horse ambulance, and heard the driver say to an orderly: "We have brought down General Getty, badly wounded, and must go back to Fredericksburg right away." "Now is my chance," thought I, and springing to my feet, I sought the medical director, who cheerfully gave me an order to go back in the ambulance, so that I left before my professional associates were awake.

---

* This is an abstract from an unpublished paper by the late W. T. G. Morton, M.D., of Boston, to whom the world is so deeply indebted for his early investigations of ether anesthesia. It was written soon after the Battle of the Wilderness in May, 1864, and has been furnished for publication by his son, Dr. Wm. J. Morton of New York City, by request of Dr. Henry O. Marcy of Boston. As an introduction we quote the following from the valedictory address delivered by Dr. John H. Brinton to the graduating class of Jefferson Medical College in 1892:

"Let me, from personal reminiscence, relate an anecdote in point: In the early summer of 1864, during the fierce contest in the Virginia Wilderness, I was present officially at the headquarters of Lieutenant-General Grant, on whose staff I had previously served. When in conversation with him, an aide approached and said to him that a stranger, a civilian physician, wished to see him for the purpose of obtaining an ambulance for his personal use in visiting the field hospitals. The answer of the General was prompt and decided: 'The ambulances are intended only for the sick and wounded, and under no circumstances can be taken for private use.' This response was carried as given to the waiting applicant, a travel-stained man in brownish clothes, whom at the distance I thought I recognized. I went to him and found that he was Dr. W. T. G. Morton. I asked him to wait a minute, and returned to the General. On repeating his request I received the same answer. 'But, General,' I ventured to say, 'if you knew who that man is I think you would give him what he asks for.' 'No. I will not,' he replied. 'I will not divert an ambulance to-day for any one; they are all required elsewhere.' 'General,' I replied, 'I am sure you will give him the wagon; he has done so much for mankind, so much for the soldier; more than any soldier or civilian has ever done before, and you will say so when you know his name.' The General took his cigar from his mouth, looked curiously at the applicant, and asked: 'Who is he?' 'He is Dr. Morton, the discoverer of ether,' I answered. The General paused a moment, then said: 'You are right, Doctor, he has done more for the soldier than any one else, soldier or civilian, for he has taught you all to banish pain. Let him have the ambulance and anything else he wants.' Not only this, but I have learned from a printed letter of Dr. Morton, recently sent me by his family, that the hospitalities of the headquarters—ambulance, tent, mess and servant—were afterward tendered him during his stay, by order of the general commanding."

Fredericksburg is nine miles distant from Belle Plain, with which it is connected by two main roads, and just now by a score or so of avenues, constructed for existing emergencies. The country, all the way between these points, is stripped entirely bare of fences, stock and products of whatever description, and, in the entire distance, I do not remember to have seen more than six houses. Immediately back of the landing at Belle Plain a range of hills stretches away to the east in abrupt, precipitous angles, with deep ravines ribbing their sides, through which roads have been constructed, along which the immense trains climb with difficult ascent, often overturning, sometimes breaking down, utterly. On the summit of this range of hills are thick growths of low timber, while the slopes are strewn with patches of thicket—mostly of pines and scrub oak. The place is inexpressibly wild and desolate, and the only living beings visible were teamsters, wounded soldiers and mounted patrols.

In one dreary defile up came four men from behind us, and rode past at a brisk trot, two on each side. As they wore the Federal uniform, neither the driver nor myself mistrusted them, until, as if by magic, two each seized one of our leading horses, while the other two cut the reins and traces, and away they went. They were a quartette of guerillas, who thus helped themselves to a good pair of Uncle Sam's horses, leaving us to pursue our journey with a single pair instead of four-in-hand. The audacity of the rebel guerillas is astonishing. although they invariably seek unarmed or wounded subjects for plunder, and keep a wide distance from our patrols.

At last we rattled over a pontoon bridge, and entered the remains of the war-desolated city of Fredericksburg, once one of the most beautiful and flourishing places in Virginia. It is regularly laid out, the streets are shaded with trees, and although the houses are not noted for their architectural beauty, yet they are built with an idea of simplicity and of convenience which can not but charm the beholder. Nearly every house has a large garden, both in the front and rear, filled with all kinds of vines and flower trees. . . .

At first, there was confusion and lack of supplies, causing much suffering and discomfort. But Surgeon Dalton, the efficient medical director, soon had everyone made as comfortable as circumstances would permit, and the Sanitary and Christian Commissions did their share of the noble work. Scores of volunteer nurses, state relief agents and other good Samaritans did what they could to relieve the necessities and alleviate the sufferings of these brave wounded men.

The ambulances could not have brought one-tenth part of them, and the rest were brought in wagons, eleven or twelve miles over the remains of a planked road, worn by war-travel. In places the larger wagons had to be pried out of the deep holes with trimmed trees. The delays of the entire train from this cause were frequent and long. The depth of these holes, and the instinct and habit of the lead and middle team of mules to trot away from a wagon in a sudden descent, in order to escape the whipple-trees, inflicted on the unfortunate wounded, blows and jars excruciatingly torturing and that wasted their remaining vitality. Over every rod of the way and in the best two-horse spring ambulances, a jarring motion was communicated by the absence of half the planks on the planked side of the road, and the ruts and holes cut into the clay side during a week's rain by the transportation machinery of an army of a hundred thousand men. On such a highway, and in such a manner, did these poor fellows, who stretch their hands out of these ambulances and army-wagons for tin-cupfuls of water. painfully travel—some with arms off at the shoulder, some with legs off above the knee, some with an arm and leg both off, hundreds shot through the leg or arm or the breast, some with horrible wounds of the face—even to the loss of the jaw and the destruction of speech—all presenting, in the aggregate, every possible variety of gunshot wound. . . .

Having been assigned quarters in a fine old mansion, I commenced going the rounds of the buildings used as hospitals, to administer anesthetics. There was at first a lack of supplies, and many of the wounded, who had been jolted over hard roads some eight and forty hours, were in a bad condition. Several hundred, packed into a church or hall, without change of clothing or washing, made the atmosphere unbearable almost, and gangrene and erysipelas began to make their appearance, but this was soon remedied.

One of the principal hospitals was the Baptist Church, which was literally packed with wounded. The tank intended for immersion was used as a bathing tub, and the operations were performed in the pastor's small study, back of the pulpit.

The Free Masons' hall was also filled with wounded, and there remains much of the paraphernalia of the lodge in which Washington received his degrees. I found one poor fellow who was a member of the fraternity, and at his request had his bed moved to the platform once occupied by the master's chair, where he lay and gazed upward at the mystic letter "G," as if secure under its protection.

It was a noteworthy fact that, although each of the great armies which met in the Battle of the Wilderness had at least 250 pieces of artillery, there were not in the hospitals at Fredericksburg a dozen men wounded by cannon shot or shell. Out of the 3,000 reported as wounded in Hancock's demand, not one had received a shot or shell wound from artillery. It was also noticed that many of the wounds received were caused by balls which had glanced from trees or rocks, inflicting comparatively slight injuries. I was informed by a division surgeon that out of about 1,000 wounded under his charge, not over thirty were permanently disabled. . . .

By Thursday, May 12, the wounded at Fredericksburg were all well cared for. Surgeons and nurses had arrived. The Sanitary and the Christian Commissions were actively at work. All those patients who could bear transportation were being sent away, and I was beginning to think of making a visit to the front, when a summons came requesting me to hasten thither. There had been fearful fighting, as General Grant had swung around his army out of the bloody Wilderness, and he now faced Spottsylvania Court House.

Leaving Fredericksburg in company with an officer of my acquaintance, we started for headquarters. Just out of the town we passed some four or five hundred army wagons, each one with its four or six horses or mules ready for service, yet near the supplies of forage.

There were also large droves of cattle, brought from the western states for the use of the Army, and killed as they were needed. The road. if road it may be called. was wretched indeed, the horses often sinking in mud holes to the saddle girths. Through this ambulances and wagons were floundering along, carrying the wounded to Fredericksburg, while others, only slightly injured, plodded along on foot. Occasionally we passed an impromptu camp, where these slightly wounded men had stopped to rest, and several newly made graves showed where some poor fellows had made their last halt.

It is the most sickening sight of the war, this tide of the wounded flowing back. One has a shattered arm, and the sling in which he carries it is the same bloody rag the surgeon gave him the day of battle; another has his head seamed and bandaged so you can scarcely see it, and he weaves like a drunken man as he drags along through the hot sun; another has his shoe cut off, and a great roll of rags wound around his foot, and he leans heavily on a rough cane broken from a pine tree; another breathes painfully and holds his hand to his side, where you see a ragged rent in his blouse; another sits by a puddle, dipping water on a wounded leg, which, for want of dressing since the battles, has become badly inflamed; another lies on a plat of grass by the roadside, with his browned face turned full to the sun, and he sleeps. So I passed hundreds, in riding a few miles. They move along silently, making no complaints, asking no questions and no favors of the passerby. Such heroic bravery and fortitude are only surpassed by their valor on the field of battle.

The appearance of the country along our way is calculated to make the scene all the more impressive. The two hostile armies which have occupied this part of the Old Dominion ever since the war begun, have fought over nearly every acre of this ground. Although there were fine farms and luxurious old Virginia homes along this road, not a house, not even a rail, is to be seen. Desolation seems to have marked it for her own. At long intervals the blackened walls, ruins of Virginia, stand as a ghostly record of rebellion. The plains are already grown up with wild bushes, and are fast taking the appearance of the old battlefields to which we used to make long pilgrimages with curious interest.

On reaching the top of an eminence, I at last saw our line, in the shape of a horseshoe, somewhat straightened out, with troops all around, in readiness for instant attack, while beyond them, crouched in rifle-pits, were our pickets. Riding through regiments and batteries I reached a house which had been pointed out to me as General Grant's headquarters, but found on my arrival that he had moved so that the building might be used as a hospital. Just then several wounded rebels were brought up on stretchers, and the surgeon in charge, who had known me after Burnside's attack on Chancellorsville, invited me to administer anesthetics, which I did. All of them had limbs amputated, and seemed very grateful afterward for the kind treatment which they received. . . .

When these wounded Confederates had been attended to, the surgeon sent an orderly with me to the headquarters of the medical director of the Army of the Potomac, to whom I reported for duty, and then, as there was no need for my services, I went on until I reached the headquarters of the Army. These occupied a group of about twenty tents, pitched along the border of a piece of woodland. In front of one of these tents, the fly of which was converted into an awning, sat the lieutenant general with several officers and Mr. Dana, the assistant secretary of war.

I had been introduced to General Grant at Washington, and he at once remembered me and gave me a kindly welcome. Had I not previously known him, I should never have dreamed that so unpretending a person was the commander of so mighty a host. He is rather undersized, compactly built, and evidently able to endure great fatigue. His sandy hair is thick and bushy, as yet not marked with gray. The barber has had nothing to do about his face since the war commenced, wherefore much of the native expression of his countenance is lost under moustache and beard. A dry, straight-cut mouth and clear gray eyes are about all that are visible. On his forehead the skin, well tanned and browned by exposure, is drawn over the frontal bone tight and smooth as a drumhead. It is said that not a wrinkle or a frown is ever seen there. It is the expression of immovable calmness. His forehead is higher and better than it appears to be, for it is concealed by coarse, bushy hair. Incessant, close and rapid thought is going on there, however quiet the external signs may be.

The general says but few words, yet he is not morose or repulsive. This reticence is not the result of misanthropy or ill-nature, for no trial of temper ruffles the calmness of his mind. No officer is more approachable. There is no general commander so ready to dispense with ceremony or the show of rank, to listen carefully and to reply plainly to the point.

I found General Meade in excellent spirits, and he gave me the agreeable intelligence of a brilliant success which had been achieved that morning, "before breakfast," as he expressed himself. Before day, General Hancock ordered a slow advance of his line of battle in the direction of the line of intrenchments held by Ewell's corps, who were in his front. Slowly and surely did his men creep forward and the dawn of day found them close on the sleeping and unsuspecting rebels.

The firing amounted to little or nothing; there was no time or necessity for such work. The shelter tents of the enemy, erected near their line of entrenchments, were entered by our troops before the rebels had time to escape from them; they were surrounded, cornered, hemmed in and fairly dumbfounded, and on the command being given to surrender they at once dropped their arms and became passive, resistless prisoners of war.

The artillery had not time to limber up and get away or fire a single volley before our dashing troops were among them. Even their general, whose quarters were somewhat in the rear, could not escape, and he, together with the greater portion of his command, became subservient to the orders and commands of the redoubtable Hancock. The prisoners taken numbered between six and seven thousand, including two generals, and some thirty pieces of artillery were also captured. This was the first battle of Spottsylvania Court House. After having narrated the morning's work, as he called it, General Grant suggested to me that it would be well to visit the scene of this sanguinary contest.

Although the rain fell in torrents, I followed his advice, and witnessed a scene which was horrible enough to curdle the blood of the coldest. The angle of the works at which Hancock entered, and for the possession of which the savage fight of the day was made, is a perfect Golgotha.

In this angle of death the dead and wounded rebels lie, literally in piles—men in the agonies of death groaning beneath the dead bodies of their comrades. On an area of a few acres in rear of their position lie not less than a thousand corpses, many literally torn to shreds by hundreds of balls, and several with bayonet thrusts through and through their bodies, pierced on the very margins of the parapet, which they were determined to retake or perish in the attempt. The one exclamation of every man who looks on the spectacle is: "'God forbid that I should ever gaze on such a sight again."

On Saturday morning, May 14, I was awakened by the booming of cannon, and learned that the enemy were endeavoring to regain their lost position. After a hasty breakfast, I began to visit the field-hospitals, to produce anesthesia where capital operations were to be performed. The wounded were brought to these field-hospitals by the newly organized ambulance corps of their respective divisions. When there was any heavy firing heard the ambulance corps, with its attendants, stationed nearest to the scene of action, started for the wounded. The ambulances were halted near by, and the attendants went in with stretchers to bring out the wounded. The rebels did not generally fire on those wearing the ambulance badges.

On the arrival of a train of ambulances at a field-hospital the wounds were hastily examined, and those who could bear the journey were sent at once to Fredericksburg. The nature of the operations to be performed on the others was then decided on, and noted on a bit of paper pinned to the pillow or roll of blanket under each patient's head. When this had been done I prepared the patients for the knife, producing perfect anesthesia in an average time of three minutes, and the operators followed, performing their operations with dexterous skill, while the dressers in their turn bound up the stumps. It was surprising to see with what dexterity and rapidity surgical operations were performed by scores in the same time really taken up with one case in peaceful regions.

When I had finished my professional duties at one hospital, I would ride to another, first arranging at what hour I would next return. In the garden of one house used as a hospital I noticed over twenty lifeless and mangled forms, bloody and ghastly—men without heads, heads without bodies, hands wanting arms. Some had died with fierce expressions on their faces; others who passed quietly from the stormy shores of time to the realms of eternal peace. The dead are buried where they fall, or near the hospitals in which they die. Their names are carefully written on wooden headboards, and entered into registers.

Early on the morning of Wednesday, May 18, the whizzing of shells announced that the second and great battle of Spottsylvania Court House had been commenced. It was four o'clock a. m. when the Union skirmishers advanced. The rebels were there, armed and vigilant. Both sides opened with cannon. Smoke and mist hung pale, heavy and motionless over the troops. On the right was Gibbons' First division. The Irish Legion had just joined them. They had seen some service on the Blackwater and Nansemond rivers, near Suffolk, during the investment of that place by Longstreet, but had never known the reality of a battle.

On the right, the Irish Legion charged with a fierce, wild shout. Two hundred yards of clear field had to be traversed before the first line of the enemy's breastworks could be reached; a battery of four brass pieces played on our men incessantly as they advanced on a double quick. All this time the sharpshooters were busy; sufficient light was lacking to enable them to sight their pieces with precision, but many an officer owes his death to their marksmanship.

At last the field is crossed. The distance was short—only two hundred yards. Who does not believe it seemed a lifetime to many of those men, who, with bent body and erect bayonet, won their perilous way, foot by foot, through whistling balls, bursting shells, gnawing grape. The rebels fly from the first entrenched line. Our brave fellows clamber over cheerily and capture a few dilatory sharpshooters, who lingered too long at their post. About midway between the first and second parallels, the line of the legion grows confused—their pace waxes slow by degrees, and finally halts, preparatory to breaking—to retreating.

They did fall back a short distance, but the veterans of the old First and Second divisions were at hand. They took no notice of confusion, and heeded the driving bullets no more than a pelting rain. Through the pines they ran, with fixed bayonets, searching in vain for the rebels. A shout rent the air, and the second line of breastworks was won. The rifle pits in front were those which had been abandoned by us; but they were filled with rebel sharpshooters, who were soon dislodged and driven through a second line and behind a thick and impenetrable abattis, which was of a most formidable character. On examination it was deemed best not to attempt charging through this barrier, and the troops fell back in good order, although exposed to a galling fire of shell and canister from both flanks.

The sun went down red. The smoke of the battle of more than two hundred thousand men destroying each other with villainous saltpeter through all the long hours of a long day, filled the valleys, and rested on the hills of all this wilderness, hung in lurid haze all around the horizon, and built a dense canopy overhead, beneath which this grand army of freedom was preparing to rest against the morrow.

On Thursday, May 19, I learned confidentially that General Grant intended to swing around toward Richmond, and I determined that I would swing around toward Washington, where imperative business before Congress demanded my presence. Before leaving I rode with a friend along the entire front of the Union line, an undertaking that at any time before would have been attended with too much peril to make the excitement compensate for the personal risk it involved. The life of our soldiers in intrenchments affords a theme on which a chapter might be written. I could with difficulty imagine that a few hundred yards only intervened between them and a foe as impassible as it is unyielding. Here were groups of officers chatting, writing letters and reading, and all along were privates making and drinking coffee, card playing and talking over the incidents of the late battle through which they had passed thus untouched by rebel bullet or shell. But all were ready to spring in an instant to musket or cannon.

From a house used as a signal station, and with the aid of a powerful telescope, I could see the enemy's works, a battery of sixteen guns, commanding the very place where I stood. These were only a small portion of the artillery they had posted and waiting for us. Their first line of works was firmly sodded on the outside, showing that it had been built for some time. At intervals were fox or rifle pits for sharpshooters. The line in our immediate front was a mile and a half long, and formed the arc of a circle. Behind this were two other lines, mainly under cover of woods. A captured rebel officer says that after the battle of Gettysburg from fifteen to twenty thousand men were employed constructing these works, and others between here and Richmond, to cut off any approaches, in the future, of our army on their capital. The chosen position was on a commanding ridge, and to the right and left densely wooded, leaving an open field in front over which they doubtless hoped General Grant would advance to attack them. But the general chose instead to make a flank movement rather than to lose thousands by an assault. Leaving the front on Friday, May 20, to return to Fredericksburg, I passed train after train of ambulances and wagons laden with the wounded, some groaning and writhing in anguish, but none complaining.

I saw at Fredericksburg a number of our wounded, left behind in the Battle of the Wilderness, but brought in by a detachment sent after them. Never were a set of men more rejoiced than were these poor sufferers on seeing our men come to rescue them. They had been left with a few surgeons and attendants, and supplies for a number of days, but some roving squad of rebel cavalry who came in shortly after our departure, helped themselves freely to sugar, salt, hard tack and whatever else they wanted. Had our poor men been left there a day or two longer they must have died of starvation.

Some time after the arrival of the squad above mentioned, Hampton's Legion of cavalry arrived, and its commanding officer promptly placed a guard over the hospitals and declared nothing more should be taken, yet his men took all the sugar and coffee they could find in the haversacks of dead or wounded. Dr. Armstrong, of the Eleventh Virginia cavalry, dressed the wounds of our men, and showed them great kindness, for which act of humanity his name deserves honorable mention.

I found Fredericksburg as I had left it—one vast hospital. But during the week of my absence great changes for the better had been made. Wounded men arriving covered with dust and blood, weary and faint, were placed in the hands of the nurses in the wards they were to occupy; their tattered garments, as they often are, removed, the purifying and soothing application of a warm bath made, the wound is examined and ministered to by the surgeon in attendance, and, arrayed in clean and suitable apparel, the patient was placed gently on a hospital couch with bedding well aired and clean. The process was similar in the case of all who were brought in. There is no crowding, no confusion. Each ward had its designated number of occupants, its number of nurses—one nurse being usually assigned to ten men, while the surgeons had from eighty to a hundred patients assigned as the complement of each. This arrangement secured good and sufficient attention to the patients in all cases where those having charge showed ordinary intelligence and fidelity.

The patients appeared cheerful and patriotically happy. A shot in the arm, or leg, or side, or shoulder, had prostrated many of them. Sometimes a bandaged brow or jaw suggested a tale which told itself, and occasionally a woefully attenuated form spoke of wasting illness. But almost every occupant of the long rows of beds was in the very best of spirits, cheerful in the memory of duty done, and exultant in the prospect of that which is to be consummated. What was particularly noticeable in these soldiers was their modesty in speaking of themselves, their generosity in mentioning their comrades. They could scarcely be brought to dwell on their own exploits and disasters, and reverted with the brave fondness of military devotion to those of the men with whom they had battled side by side. These soldiers of the Union are as enduring on the sick bed as they are valiant in the field. They do not whine nor grumble. .

General Grant having decided to evacuate Fredericksburg, the wounded were removed to Washington in steamers. . . . The scene at the Washington wharf was a painfully interesting one. The high bluffs commanding a view of the landing were thronged with women and children, all in attitudes of expectation and anxiety. The entrance to the gangway was similarly beset. The gangway itself was lined with groups inquiring for friends or relations, or administering to the wants of wounded soldiers. At the end of the wharf long tables were spread with such refreshments as might be required by the suffering men, and ladies and gentlemen in the service of the Sanitary Commission busied themselves in ministering to their wants. As a general rule, the wounded bear their sufferings with almost stoical firmness. Hardly a groan was heard as they were borne along the wharf on stretchers to the ambulances, although the nature of the wounds of many must have rendered the least movement extremely painful.

Time will not enable me to describe the scores of hospitals in and around Washington, where tens of thousands of unflinching heroes have received and are receiving the nation's choicest care. The minister of the gospel, the surgeon, the philanthropist and the devoted loyal women of the metropolis vie with each other in giving their time to these wounded soldiers. The poor fellows receive tender nursing, watchful guardianship by day and by night, and all the kindly ministrations that gratitude and affection can suggest.

The hospital heroes, suffering as they do, do not lead a blank, complaining life. The invalids arranged along the extensive vistas of the wards, sprinkle with numberless jokes the surface of serious conversation. Each, in spirit at least, "shoulders his crutch and shows how fields were won." Some of the wounds reported as slight are fearful enough to make the patient wince and the beholder shudder. The budding spring is too green and pleasant, the air too golden and balmy, to be in complete accordance with a scene like this. The windows and doors are wide open, and the gentle breeze streams through. The blue of the sky and the green of the meadow are mutually harmonious in beauty, and it is this which makes us feel there is such a dissonance between the scene without and that within.

As to the hospital fare, concerning which complaints are sometimes made through the papers, perhaps not always without reason, the wants of the invalids are certainly provided for, as far as may be, in a wholesome and substantial way. Luxuries and various delicacies are not to be looked for, of course.

Plain vegetables, such as potatoes, turnips, cabbage and onions, are furnished, with good bread, and, if obtainable, good butter, rice, hominy, milk, tea and coffee, fresh beef, soups, bacon, with eggs, chicken, and custard or pudding occasionally for extremely delicate palates. Many hospitals, indeed, have a less varied bill of fare than this, particularly at certain seasons of the year, when several of these articles are scarce and to be procured only at great pains and cost. But most well-managed hospitals can point to such a variety as evidence of the liberal provision made by the government for those who have been disabled in its service. In addition to this the ample stores of those grand voluntary agencies, the Sanitary and Christian commissions, are freely opened to the constant applications made by the hospitals in behalf of their inmates. These commissions furnish to the sick a great variety of articles which the government does not furnish. Jellies, canned fruits, jams, domestic wines, cordials, lemons, may serve as a sample of the various provision flowing to stanch the soldier's wounds and soothe his sorrow, from the inexhaustible fountain of sympathizing hearts at home. Warm garments to cheer him in winter, light, loose garments to promote his ease and comfort in summer, reach the soldier to gladden him, from the same source. Indeed, this love to the poor soldier, gushing forth still buoyant, tireless, irrepressible in these grand benefactions from countless home circles over the land, forms one of the sublimest spectacles of the day. It is a mighty power, too, in this struggle, that is doing more at this moment to strengthen the government and make its trying work successful, than any amount of brute force with all "war's dreadful enginery" to back it.

While I have endeavored to describe to you the mighty struggles of the Wilderness and of Spottsylvania Court House, I have also desired to demonstrate that the wounded soldier is well cared for. Countless home circles from which the young, and noble, and tenderly-endeared have gone forth in the cause of an imperiled country, may be relieved from the anguish of feeling that their loved ones, prostrated by bullet or disease, are left unregarded or without proper care and attention, to bleed, languish and die. The government has guarded with anxious vigilance against all this. Its paternal care has taken, all over the land, the form of a beautiful system of means and appliances aiming at the relief, comfort and healing of the maimed and war bruised. And the soldier's kin and friends may feel and know, and take comfort as they do so, that if the fate of war should number their most cherished ones among the hosts whom sickness seizes or bullets pierce, they will find on the hospital couch the ministry of kind and skillful hands to soothe and mitigate their pangs, and, if God will, win them back to health.

For myself, I am repaid for the anxiety and often wretchedness which I have experienced since I first discovered and introduced the anesthetic qualities of sulphuric ether, by the consciousness that I have thus been the instrument of averting pain from thousands and thousands of maimed and lacerated heroes, who have calmly rested in a state of anesthesia while undergoing surgical operations, which would otherwise have given them intense torture. They are worthy of a nation's gratitude—happy am I to have alleviated their sufferings. For the dead heroes we mourn—but let all the patriotic benevolence, and science, and philanthropy of the republic be brought into requisition for the benefit of the wounded.

THE INTRACELLULAR TOXIN OF BACILLUS PYOCYANEUS.[*]

DONALD R. MACINTYRE.
Assistant in the Hygienic Laboratory, University of Michigan.
ANN ARBOR, MICH.

The object of this research was to ascertain whether or not *Bacillus pyocyaneus* contains an intracellular toxin. Some years ago Buchner obtained from this organism a large quantity of a pyogenetic proteid. He took the germ substance from potato cultures, rubbed it up with water and then treated it with about fifty volumes of a 0.5 per cent. solution of caustic potash. This formed in the cold a mucilaginous mass, which dissolved at the temperature of the water bath and after being heated for several hours was filtered and acidified with acetic or hydrochloric acid. The acid threw down a precipitate, which was collected, washed with water, and was injected subcutaneously into animals. It was also placed in sterilized spindle-shaped glass tubes, and introduced under aseptic precautions under the skin of rabbits. After from two to three days the tubes were removed and found to contain, in addition to some of the proteid, several cubic millimeters of fibrinous pus, which proved to be sterile.

In 1889, Charrin and Roger, working with *Bacillus pyocyaneus,* made the experiments which may be said to be the starting point of all subsequent work on agglutination. These facts made it desirable to ascertain whether or not this organism contains an intracellular toxin.

My own work may be summarized as follows: Pure cultures were grown in the large tanks used in this laboratory, and after fourteen days, the germ substance was removed from the agar, precipitated with alcohol, collected on a hard filter and extracted with alcohol and ether. The toxicity of the germ substance for guinea-pigs is shown in Table 1.

TABLE 1.—THE TOXICITY OF THE POWDERED GERM SUBSTANCE OF BACILLUS PYOCYANEUS WHEN INJECTED INTRAPERITONEALLY INTO GUINEA-PIGS.

Protocol Number	Weight.	Amount Injected, mg.	Results.	Hours.	Proportion of Toxin to Body Weight.
1	215	43 00	+	12	1 to 5,000
2	250	50 00	+	12	
			(2 + in 12 hours.)		
3	230	23 00	+	12	1 to 10,000
4	190	19 00	+	12	
			(2 + in 12 hours.)		
5	290	14 50	+	12	1 to 20,000
6	190	9 50	+	12	
			(2 + in 12 hours.)		
27	180	4 50	+	12	1 to 40,000
28	195	4 86	+	12	
			(2 + in 12 hours.)		
21	200	4 44	+	12	1 to 45,000
22	245	5 44	+	12	
			(2 + in 12 hours.)		
7	250	5 00	+	12	1 to 50,000
8	230	4 60	+	12	
17	220	4 40	+	12	
18	210	4 20	+	12	
			(4 + in 12 hours.)		
15	240	4 36	—		1 to 55,000
16	230	4 18	—		
19	235	4 27	+	24	
20	240	4.36	—		
			(1 + in 24 hours; 3 —.)		
23	180	3 00	—		1 to 60,000
24	215	3 54	—		
13	190	3 166	—		
14	265	4 401	+	24	
			(1 + 24 hours; 3 —.)		
25	210	3 23			1 to 65,000
26	305	4.69	+	24	
11	210	3 23	—		
12	220	3 384	+	12	
			(2 + in 12 to 24 hours; 2 —.)		
9	315	4 20	—		1 to 75,000
10	260	3 466	—		
			(2 —.)		

It will be seen from Table 1 that the powdered germ substance of *Bacillus pyocyaneus* is surely fatal to guinea-pigs when injected intraperitoneally in the proportion of 1 part to 50,000 parts of body weight.

When injected subcutaneously in guinea-pigs, even in as large a quantity as 1 part of the toxin to 10,000 of body weight, the only inconvenience that resulted was a slight swelling at the point of inoculation, followed by temporary loss of weight. Subcutaneous injections did not give immunity to subsequent intraperitoneal treatments.

These results show that the toxin is not destroyed, although it is slightly diminished at the temperatures given in the tables.

---

[*] This paper and the two which follow are from a series of studies of bacterial cells, research in the Hygienic Laboratory of the University of Michigan, 1903.

TABLE 2.—Toxicity of the Germ Substance of Bacillus Pyocyaneus Injected Intraperitoneally Into Guinea-Pigs After Being Heated.

Number.	Weight.	jected, mg.	Results.	Hours.	Proportion to body weight.
30	240	4.40	+	12	1 to 45,000
29	180	4.50	+	12	1 to 40,000
30	240	4.40	+	12	1 to 45,000
31	140	2.80	+	12	1 to 50,000
(30 minutes at 75 C.)		(3 + in 12 hours.)			
32	250	5.00	+	12	1 to 50,000
33	230	4.60	+	12	
34	225	5.00	+	12	30 minutes
35	245	6.10	+	12	at 100 C.
		(4 + in 12 hours.)			
36	220	4.40	—		1 to 50,000
41	190	3.80	+	12	
37	190	4.20	+	12	1 to 45,000
40	230	5.11	+	12	
38	240	6.00	+	18 days.	1 to 40,000
39	205	5.12	+	12	
(30 minutes at 110 C.)		(5 + in 12 hours to 18 days, 1 —.)			
44	245	4.9	+	18	1 to 50,000
45	250	5.00	—		
47	235	5.22	+ -	18	1 to· 45,000
43	225	5.00	+	18	
42	200	5.00	+	16 days	1 to 40,000
46	220	5.50	+	12	
(30 minutes at 120 C.)		(5 + in 12 hours to 16 days, 1 —.)			

The intracellular toxin can not be extracted, at least, not in appreciable quantity, by physiologic salt solution; 100 mg. of the germ substance was suspended in 50 c.c. of physiologic salt solution, placed in a sealed tube, and vigorously agitated in a mechanical shaker for twelve hours, at the end of which time the emulsion was filtered through heavy Swedish filter paper, and the filtrate found to be without toxic effect. This is found to be true, whether the germ substance was freshly taken from agar cultures or had been previously extracted with alcohol and ether.

When the germ substance was extracted with 1 per cent. of sulphuric acid and this extract treated with absolute alcohol, a precipitate was obtained. This precipitate, after having been washed until the washings were free from acid, dried and injected into animals, proved to be toxic, but much less so than the original germ substance.

While no appreciable amount of toxin could be obtained from the cell substance, a hemolytic body was extracted with physiologic salt solution; 100 mg. of the germ substance which had been hardened by the action of alcohol and ether, was suspended in 50 c.c. of physiologic salt solution and agitated for twelve hours, after which it was filtered through heavy Swedish paper. To three tubes containing each 10 c.c. of a 5 per cent. solution of defibrinated blood, the following quantities of physiologic salt solution extract of the germ substance were added:

Tube 1 received 10 c.c. of the extract.
Tube 2 received 1 c.c. of the extract.
Tube 3 received 0.1 c.c. of the extract.

These tubes were placed in the incubator for twenty-four hours, at the end of which time complete hemolysis had occurred in Tube 1. In Tube 2, about one-third of the blood had been dissolved, while in Tube 3 the hemolytic action was found to be very slight.

The hemolytic substance was also extracted from the unhardened fresh germ. Some of this germ substance was shaken with physiologic salt solution for twelve hours and then passed through a Berkefeld filter; 13 c.c of this filtrate was found to completely dissolve all the blood corpuscles in 10 c.c. of a 5 per cent. blood solution in twenty-four hours at incubator temperature.

My conclusions may be stated as follows:

1. *Bacillus pyocyaneus* does contain an intracellular toxin.
2. This toxin can not be extracted from the cell by physiologic salt solution. It is in part extracted by dilute sulphuric acid.
3. Heat to 120 C. in the autoclave continued for thirty minutes only slightly diminishes the toxicity of the cell substance.
4. The cell substance of *Bacillus pyocyaneus* contains a hemolysin, which may be extracted from the cell, either in the fresh state or after treatment with alcohol and ether by physiologic salt solution.
5. The minimum lethal dose of the cellular toxin is for guinea-pigs when given intraperitoneally about 1 part of the cell substance to 50,000 parts of body weight.
6. When injected subcutaneously in guinea-pigs in the proportion of 1 part of the cell substance to 10,000 parts of body weight or less no permanent ill effect results.
7. Subcutaneous injections do not give immunity to subsequent intraperitoneal injections.

THE EFFECT OF PUTREFACTIVE BODIES ON THE CHEMICAL TESTS FOR MORPHIN.*

M. W. CLIFT.
ANN ARBOR, MICH.

In at least three important trials for murder, the possibility of putrefactive products being mistaken for morphin has arisen. The first of these was the Sonzogna trial at Cremona, Italy, in which it is probable that the experts confounded a putrefactive body with morphin. This substance was extracted from either alkaline or acid solutions with ether, but could not be removed with amylic alcohol. It reduced iodic acid, but in its other reactions, also in its physiologic properties, it bore no close resemblance to morphin. In the Buchanan case in New York every test for morphin was duplicated with putrefactive products, so that the distinguished chemists present were not able to tell which of the two portions contained the alkaloid. In the case of Dr. Urbino de Freitas of Oporto, Portugal, who was accused of attempting the wholesale murder of his wife's family by the administration of morphin, the toxicologists who investigated the case relied for the detection of this alkaloid on the color reactions applied to residues obtained by following Dragendorff's method. The chemists reported not only morphin, but narcein and probably delphinin. The defense questioned the reliability of the tests used, and many of the most prominent toxicologists of Europe became more or less involved in the controversy.

These cases are enough to illustrate the desirability of further investigation along this line. Many methods have been suggested for the extraction of morphin in medicolegal cases, without confounding it with any putrefactive body. The best of these methods is that advanced by Kippenberger, who holds that the alkaloidal tannates are soluble in glycerin, while the putrefactive bodies likely to interfere with the tests for morphin are insoluble in this agent. A careful reading of Kippenberger's paper shows that this statement does not rest on any extensive experiments. The method of work in the investigation herewith reported may be described as follows: Six liter flasks were cleaned, rinsed with distilled water, and in each of these there was placed 500 gm. of chopped beef liver and 1,000 c.c. of distilled water. These flasks were then placed in the autoclave and sterilized at 120 C. for forty-five minutes. After having been heated, the flasks were allowed to stand at room temperature for twenty-four hours, when their sterility was proven by inoculating tubes of beef tea with material from each flask. After this these flasks were treated as follows:

---

* See note to previous paper.

No. 1 was inoculated with *Bacillus pyocyaneus;* No. 2 was treated with 100 mg. of morphin and then inoculated with *Bacillus pyocyaneus;* No. 3 was treated with 200 mg. of morphin and then inoculated with *Bacillus pyocyaneus;* No. 4 was inoculated with *Bacillus coli communis;* No. 5 was inoculated with *Bacillus coli communis* and treated with 100 mg. of morphin; No. 6 was treated with 200 mg. of morphin and inoculated with *Bacillus coli communis.*

All of these flasks were then placed in the incubator at 37 C., where they were kept for two weeks. At the expiration of this time they were all autoclaved at 120 C. for forty-five minutes. A 2 per cent. solution of tannic acid in glycerin was poured into each flask in an amount equal to the mass therein contained. The flasks were then placed in an incubator and kept for forty-eight hours at 40 C. Then the flasks were removed from the incubator, the contents strained through muslin, and the filtrate heated on a water bath at 60 C. for one-half hour in order to bring down the coagulable proteids. After filtration through paper the filtrates were shaken with twice their volumes of petroleum ether. After separation of the ether the material was heated in order to drive off traces of the solvent, and then rendered slightly alkaline with sodium hydrate and shaken with chloroform. The chloroform extract from each flask promptly reduced iodic acid and potassium permanganate. Like results were obtained with amylic alcohol extracts from an alkaline mixture. None of these residues gave either the ferric chlorid or the Froehde test for morphin in a satisfactory manner. Great difficulty was experienced in obtaining clean pure residues. This was true with both the chloroform and amylic alcohol extracts, and it was found to be necessary to repeatedly take up the residues with water slightly acidulated with acetic acid, and again render alkaline and shake with the solvent. Crystalline residues were finally obtained from only two flasks, one of which contained morphin, while the other did not. The crystals in both of these cases seemed identical microscopically with those obtained from an alkaline solution of morphin shaken with chloroform, and the chloroform extract evaporated. The crystalline residue was so small in amount that the possibility of determining the melting point was excluded.

It must be evident from these results that a satisfactory method of extracting morphin in medicolegal examinations is not furnished by Kippenberger.

THE EXTRACTION OF A TOXIN FROM LIVER CELLS.

A PRELIMINARY REPORT.*

V. C. VAUGHAN, M.D., LL.D., J. F. MUNSON, A.B.,
AND
FRANK R. SPENCER, M.D.
ANN ARBOR, MICH.

The liver of an ox, just after the animal had been slaughtered, was obtained and passed through a sausage machine, finely dividing the structure and removing a considerable portion of the connective tissue. This finely divided material was stirred up with five times its volume of 1 per cent. sulphuric acid, and the mixture was heated for three hours and thirty minutes in the water bath at a temperature of 81 C. Then it was heated for three hours longer over the direct flame at 100 C. and filtered. The filtrate proved to be a clear, light amber-colored fluid, which was added drop by drop to three volumes of 95 per cent. alcohol, with constant stirring. The precipitate which formed was collected on a hard filter, washed with alcohol, and then dissolved in a minimum amount of water. This solution was again precipitated by adding it drop by drop to three times its volume of 95 per cent. alcohol. This precipitate was washed with alcohol and ether, then redissolved in distilled water. This process was repeated until the aqueous solution failed to give a test for sulphuric acid with dimethylamidoazobenzol. The substance thus obtained was dried in vacuo and ground, first in a porcelain and then in an agate mortar.

The cleavage product thus obtained, when dissolved in water and injected intraperitoneally into guinea-pigs and rabbits, kills the animal when the proportion is 1 part of the extract to 500 parts of body weight. When used in smaller quantities there is more or less marked emaciation, depending on the quantity injected, from which the animal recovers very slowly. So far we have not been able to secure any marked degree of immunity by beginning with small doses and gradually increasing the quantity.

After acute poisoning with the quantity above mentioned, postmortem examination shows the liver of the dead animal to be deeply congested. The spleen is soft and mottled, with dark and pale red spots. The kidneys show no gross changes, but the adrenals are markedly congested. The gastric and mesenteric vessels are greatly dilated, and there are frequently found small hemorrhagic areas under the peritoneum. We are now engaged in studying the effects of very small doses frequently repeated on the structure of the liver and other organs.

A METHOD OF MICROSCOPIC OBSERVATION BY MEANS OF LATERAL ILLUMINATION.

D. J. DAVIS, M.D.
CHICAGO.

(From the Pathological Laboratory of Rush Medical College.)

INTRODUCTION.

Last year two German physicists, Siedentopf and Zsigmondy, published an article[1] in which they described an apparatus for the observation of ultramicroscopic particles. The object which they selected for examination consisted of a piece of glass through which was diffused uniformly particles of metallic gold in a very fine state of division. By means of a powerful light—either the sun or an electric arc—passed through a complicated system of condensers, a very small but exceedingly intense focus of illumination was obtained. The piece of glass containing the gold was placed in this focus so that the light entered the glass from the side. It was then observed with an ordinary microscope from above. By this arrangement none of the light entered the microscope directly. To the naked eye, or with the ordinary microscope, the glass appeared perfectly homogeneous. But by this special illumination the individual particles of gold so reflected and refracted the light that they could be observed as distinct luminous points. This being the only light that entered the microscope, the particles appeared as bright points against a dark background.

---

* See note to paper of Dr. MacIntyre.

[1] Annalen der Physik., 1903, x, 1.

Three conditions are necessary for seeing particles: First, they must not be beyond the limits of visibility of the apparatus; second, they must not be too near together, about 0.25 micron being the necessary distance in order to distinguish them from one another; third, they must have an index of refraction different from that of the surrounding media.

Siedentopf and Zsigmondy were able to calculate the size of the particles observed. Knowing the amount of gold in the glass, and then counting the number of particles seen under the microscope in a definite volume of the glass, the size of the particles could readily be calculated. They found that they could see particles as small as 0.005 micron and even smaller. This is within the limits of the size of molecules, as calculated by Van der Waals and others. Since the limit of observation had been placed by Helmholtz at about 0.2 micron, a tremendous stride was taken in reducing the limits of visibility. These authors also made observations on colloidal solutions. Mouton[2] later suggested the application of this method to bacteriologic problems.

Since then Raehlman[3] has been continuing the work. He has reported observations on colloids, sugars, glycogen, dyes, etc., in which in high dilutions numerous small particles with characteristic movements may be observed. Also he has been able to see organisms with progressive motion in filtered putrefying liquids.

Mouton and Cotton,[4] following the work of Siedentopf and Zsigmondy, suggested a modification of the method described above. This consisted in passing a concentrated pencil of light, emanating from a Nernst lamp, through a suitable piece of glass in such a way that the light is totally reflected from the upper surface of the glass or the upper surface of a cover-slip placed on it. When such a piece of glass is placed under the microscope no light will pass directly into the tube of the instrument, and any particles in the glass or between the glass and cover-slip will become illuminated and can be directly observed. They very briefly reported a few preliminary observations made at that time.

Last fall, at the suggestion of Professor Hektoen, I attempted to set up an apparatus following the fundamental idea suggested by Mouton and Cotton.

DESCRIPTION OF APPARATUS.

The source of light used is a Nernst lamp. This is a non-vacuum electric lamp, which can be screwed into an ordinary incandescent light socket. The current passes through a short filament composed largely of metallic oxids, such as magnesium, zirconium, cesium, and which consequently emits a very intense white light when raised to the proper temperature. The glass globe of the lamp is covered with lampblack on the inside, except a small round area about 0.5 cm. in diameter at its vertex. This black is used to prevent all reflection of light from the inside of the globe. In this manner we have a pencil of rays passing through the clear area at the vertex of the globe and coming from a small but intense source of light. This pencil is now passed through a condenser. For this purpose a low-power objective is very suitable and convenient. I have used one the focal distance of which is about 1 cm.

The essential part of the apparatus consists of a triangular glass prism properly supported and so placed beneath the objective of a microscope that its upper surface is horizontal. The light coming from the condenser is directed from below obliquely upward and enters the prism at right angles to one of its lateral surfaces. It passes to the upper surface of the prism and is there totally reflected and passes out through the other side of the prism. A clear conception of this arrangement is easily obtained by reference to the diagram (Fig. 1). In order that total reflection shall occur at the upper surface of the prism, it is necessary that the angle *x* made by the incident ray and the perpendicular drawn to the surface at the same point, be of a certain magnitude. Otherwise the rays will simply be refracted at the upper surface. For glass and air the magnitude of this angle, known as the critical angle, is about 41 degrees. If it is greater than this total reflection occurs; if less, the rays pass through the upper surface and are simply refracted. Therefore, for our purpose, the angle *x* must always be greater than 41 degrees. This is very important, for if there is not total reflection some of the light directly enters the microscope. Now it is also necessary that the light should enter the surface *bc* at right angles, or approximately so, for otherwise there will be troublesome refraction here. It can be seen, therefore, that the magnitude of the angle *b* of the prism is very important, since it is always equal to angle *x*, as can be readily shown geometrically, provided the ray of light enters the surface *bc* at right angles. It therefore follows that if angle *b* is less than 41 degrees total reflection will not occur.

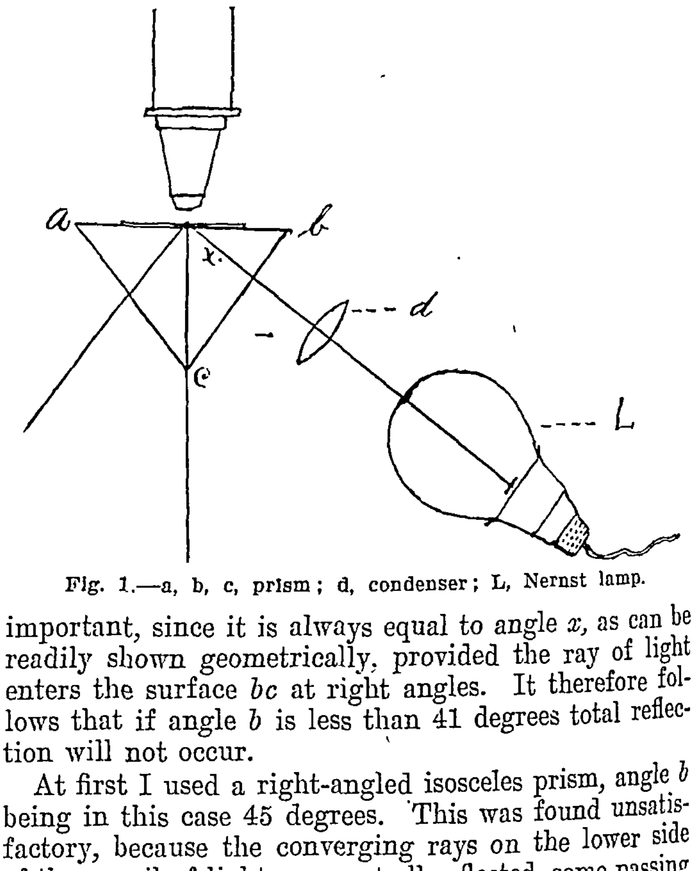

Fig. 1.—a, b, c, prism; d, condenser; L, Nernst lamp.

At first I used a right-angled isosceles prism, angle *b* being in this case 45 degrees. This was found unsatisfactory, because the converging rays on the lower side of the pencil of light were not all reflected, some passing through the surface and into the microscope above. I have, therefore, resorted to the use of an equilateral triangular prism, each angle being 60 degrees. This fulfills the necessary conditions.

For the examination of any fluid a drop or two is placed directly on the prism and a cover-slip applied. Or the fluid can be mounted with a cover-slip on a glass slide in the ordinary way, and the slide placed on the prism and separated from it by cedar oil or any substance with about the same index of refraction as the glass. The former method is much more convenient. Under these conditions the light passes through the fluid to the upper surface of the cover-slip and is then totally reflected. Any particles in the fluid in the path of the light will be made visible by the light which they reflect and refract, enlarged also by diffraction. Also the phenomenon of irradiation operates here to cause the luminous particles to appear larger than they really are. It is only this light, therefore, which enters the microscope, and it can be readily seen why it is so necessary to exclude all other light. We see in the field of the microscope the particles as bright points of light against a dark background; hence the appearance which has been likened to the stars in the heavens.

---

[2] Bull. de l'Institut Pasteur, 1903, i, 97.

[3] Münchener med. Woch., No. 48, 1903, also No. 2, 1904.

[4] Comptes Rendus de l'Acad. des Sciences, No. 26, 1903.

Attention should be called to the fact that it is necessary to have the prism surface and the surfaces of the cover-glass as nearly perfect as possible. Unfortunately a perfect surface can not be obtained. Every defect in the glass surfaces or in the glass itself, however slight, scatters the light, and, therefore, interferes with the observations. With the best cover-slips carefully cleaned and the surface of the prism polished, this difficulty is reduced to a minimum and is not serious.

SOME PRELIMINARY OBSERVATIONS.

I have made a number of preliminary observations on different substances largely to obtain some idea of the possibilities of the apparatus and also to become familiar with the appearances of various fluids and particles in order to be better able to interpret them when seen under various conditions. I have gone through exactly the same experience a novice goes through when first learning to use an ordinary microscope. It is necessary first to become familiar with the appearance of ordinary air bubbles, slight defects in the cover-glass and débris of different kinds, cells, etc. However, with a little experience, it is remarkable how easily such objects may be differentiated, considering the fact that they are only seen by lateral illumination.

Metallic colloidal solutions afford an interesting study. It is ordinarily stated that the particles suspended in these solutions are too small to be observed with the highest power of the microscope. Ehrenhaft[5] says that such particles are about 0.5 micron in diameter. I have used solutions of platinum and silver made according to the method of Bredig by forcing the metal from the cathode by means of a powerful electric spark under double distilled water. Such solutions when examined in the light show numerous bright particles, all undergoing a rapid vibratory motion. They are by no means all of the same size, varying from particles large enough to be seen with a one-twelfth oil immersion to particles so fine that they can be just observed as the faintest points of light. Colloidal silver particles in the solution which I have examined are, on the whole, larger than platinum particles and slightly more active. The silver particles also vary in color. Three distinct tints are seen—red, white and green. I have examined three different platinum solutions and I have found the different solutions to vary somewhat in the size of the particles. This may depend on the strength of the current used in making the solutions, though I have made no observations to test this.

Many of the particles are held back by filtering through a porcelain filter. The particles are then less numerous, and, on the whole, are finer. Colloidal solutions of arsenic sulphid are also very interesting. I prepared solutions of the α, β and γ sulphids as described by Picton and Linder.[6] The particles in the α and β solutions could be seen, but not those of the γ solution. On account of the greenish-yellow color of the particles and their vibratory motion a field of exquisite beauty is presented to the eye.

Of great interest is the study of animal fluids, such as serum, exudates, milk, cerebrospinal fluid, etc.

Perfectly clear blood serum which has been centrifugated shows an immense number of particles. They vary in size and have a rapid vibratory motion. Differences in the number and general appearance of the particles have been observed in sera obtained from different sources. The significance of such variations is entirely undetermined; they are certainly very suggestive.

After filtering serum through a porcelain filter the number of particles is very considerably diminished. On heating serum to about 56 C. for a few hours, a noticeable increase in the number of the particles occurs. They also appear slightly larger. This may be interpreted as a process of coagulation slowly occurring under these conditions. At room temperature also the serum changes in much the same way as at 56 C., but very much slower, the serum at 56 C. changing as much in a few hours as that at room temperature in several days. Serum kept in the ice box for two days showed no changes. These observations must be made with the serum much diluted with salt solution.

Exudates such as pericardial and ascites fluid, etc., vary very much in their appearance according to their nature. They show numerous particles—often large flakes of albumin and cells of various kinds. I have made only a few observations on such fluids.

ORGANISMS.

Micro-organisms furnish the most attractive field of any yet suggested for study by the method. Bacteria are seen as bright points of light and present an interesting sight as they tumble about in the fluid or appear in rapid motion. The method suggests itself at once as a favorable one for observing and determining motility of organisms. A few observations on typhoid bacilli have been made. They appear in rapid motion as bright points of light traversing the field in all directions, and often remind one of a display of fireworks.

The method can be applied also for observing the decrease in motility and the clumping of organisms in agglutinative tests, and I believe that it is superior to the ordinary methods used in determining the motility of bacteria.

Where the flagella are numerous, as in typhoid bacilli, they, on account of their rapid motion, appear as an indefinite flurry about the body of the organism. I have not succeeded in getting a clear picture of the flagella of the organisms when at rest.

In considering the application of this method to the study of organisms, one naturally thinks at once of the possibilities of observing the ultramicroscopic organisms for the existence of which very strong evidence has accumulated. One serious difficulty in this direction is to differentiate an organism from other particles which are usually present. If it is motile then the difficulty disappears at once. Here an excellent field opens up for the study of a number of diseases, the virus of which is known to pass through porcelain filters. For those organisms which are not motile the problem is not so easy. For example, the peripneumonia organism is just at the limit of visibility for the highest power of our best microscopes. It grows well in beef-serum bouillon, as shown by the gradual clouding of the medium after a few days. A culture of this organism was obtained from the Pasteur Institute of Paris and the organisms studied in growing culture. There was a gradual increase in the number of particles from day to day, and undoubtedly most of these were the peripneumonia organisms. But some of the particles I am sure were not organisms, for they were too large and varied too much in size. These particles unquestionably were formed as a result of changes occurring in the medium due to the growth of the microbe. The organisms, not being motile, can not be distinguished clearly from other particles which may be present. However, uniformity in the size of the particles and distinctness in their appearance speak in favor of their being organisms rather than particles of proteid or other material. In dealing, then, with these extremely small organisms, the observations must be controlled most carefully.

---

[5] Zeitschrift für physik. Chem., Oct. 31, 1903.

[6] Trans. Chem. Soc., London, 1892 and 1895.

Sections of tissue are not suited for the application of this method. In teased specimens, however, one can observe striation in muscle and the course of fibers in brain tissue. I could observe nerve fibers ramifying between cells, and in several instances I was able to see clearly the axis cylinder coming from the nerve cell and to trace it for some distance. The method may be of some value in studying the branching of the nerve fibers.

POSSIBILITIES AND LIMITATIONS.

The possibilities and limitations of the apparatus described here can only be determined by a large number of observations. New methods usually fail to meet all our predictions, yet they often become of service in some manner entirely unforeseen at first. The progress of science depends very largely on the development of new methods of technic, and consequently all such methods should be most thoroughly investigated before being discarded.

There is undoubtedly a large field for the application of this method in studying the structure of that important class of substances known as colloids, both organic and inorganic. This will include such substances as toxins, antitoxins, ferments and the like. The work already done by Raehlman is extremely suggestive, and indicates a most important field for further study.

Emphasis must be placed on the fact that the value of the method is by no means limited to the study of ultramicroscopic particles. One of its greatest uses will be to observe particles or objects, not too small to be seen by our ordinary microscopes, but which, owing to their slight refractive properties, can not now be seen by our present methods. Because of the property of this method of bringing out slight differences of refraction, I am inclined to believe it will replace, for many purposes, at least, the hanging-drop. That we can see objects not seen in the hanging-drop is illustrated nicely by the fact that red blood corpuscles in dilute acetic acid can not be seen either in hanging-drop or under a cover-slip when unstained, but under lateral illumination the stroma of the corpuscles is rendered plainly visible. Now it may be well that there exist important bodies whose refractive powers are too slight to enable them to be seen in hanging-drop, and which can not be stained by our present methods. In such cases this method of observation will be of positive value.

Since the method is applicable only to particles or small bodies in suspension, it apparently can be of no service in determining structure of tissues. The form of larger objects may be observed, but since the method does not magnify, the form of the smaller particles can not be determined.

In respect to the simplicity of the apparatus and to ease of examination of any fluid, this new method surpasses even the familiar hanging-drop.

Finally, I would call attention also to the fact that the few observations reported here were made with an imperfect apparatus.

A much more perfect illuminating system is desired, so as to obtain a smaller and more intense focus of light. This applies particularly to the study of ultramicroscopic particles, for it is generally true that the stronger the light the smaller are the particles which may be seen.

I wish here to express my thanks to Dr. Hektoen for suggestions.

THE DANGERS OF POTASSIC CHLORATE.

PAUL BARTHOLOW, A.B., M.D.
PHILADELPHIA.

Every obscure subject in medical literature should be reviewed from time to time on principles broader and more general than can usually be employed in text-books or special articles; and particularly when such obscurity is caused by a want of precision of language, by errors in the use of terms—faulty or loose terminology—and, what is more serious, by a failure to distinguish between two objects, which, though alike, are chemically and physiologically speaking, separate agencies.

For instance, a frequent and widespread source of error—and consequently of danger—arises from a confusion in the nomenclature. That is to say, potassic chlorate has been confounded, both in medical writings and in prescriptions, with potassic chlorid (KCL). Secondly, by a false analogy, the chlorate has been thought to have properties and effects identical with the chlorid, and not to be any stronger. For the belief that potassic chlorate and potassic chlorid are interchangeable, or at least as alike as twins, it is customary among some writers to blame the pharmacopeias. Our own, as it will be seen, is not liable to this criticism; but the German offends heavily. Thus a high authority[1] says: "In the pharmocopeia by the term potassic chlorate is understood potassic chlorid (KCL), while chemists apply the former name solely to the chlorate." A similar remark is made by Kobert.[2] On the inelegance of this ambiguous use of scientific terms, Virchow[3] comments with severity. In spite of these strictures from such good authority, it is possible to find in medical literature, numerous instances where the term "chlorid" is used where the "chlorate" is meant; and, sometimes in the course of the same paper both terms are employed so loosely that it is frequently difficult to tell from the context which is to be understood.[4] Finally, not only must the chlorid and chlorate be clearly separated, but both also must be carefully distinguished from the "hypochlorites" (KCLO, CaCLO2), often improperly called "chlorids," and in this false character responsible for some cases of poisoning.[5]

Into the error of confusing terms a writer in the Therapeutische Monatshefte[6] falls, while pointing out another blunder. Speaking of the danger of mixing potassic chlorate with organic or combustible substances, he cites as an instance of the non-observance of this rule the formula of a French surgeon where potassic chlorate is prescribed *in conjunction* with saccharin. The result was a violent detonation.[7] This mistake, absurd as it may seem, is natural enough. So, too, an examination of the literature will show that forgetfulness of the explosive power of potassic chlorate has been surpassed by a belief in the harmlessness of the salt. As long ago as 1830, there was a well-established opinion of this kind, an opinion based on experiments as ably conceived and carried out as most of the later ones. Thus, in that year, we find the matter lucidly and with great practical definiteness set forth by Professor Tully. He repeatedly gave, by way of trial, not only to his students but to himself, an ounce of potassic chlorate at a dose. No ill effects beyond slowing of the pulse and moderate intoxication were seen. [illegible] evidence of the accuracy of Tully's [illegible] he first satisfied himself by preliminary tests that he was using true potassic chlorate and not some colorable substitute. In this respect, as well as in other ways, his investigations compare favorably with those carried on in the laboratories of Europe.

Subsequently, Isambert[9] declared himself in support of the belief in the harmlessness of potassic chlorate. He took it in doses of 20 grams, and observes that it is "d'une innocuité singulière." Again, Chaussier affirms that it may be taken without solicitude (inopinément). Another reports the case of a man who inadvertently took 9 drams without bad results. Such cases were common at one time—a fact remarked by Jacobi, who was one of the first to point out the danger. It was customary to give potassic chlorate in large amounts. It was known not to be very soluble, and for this reason as well as for its postulated safety, it was often administered in saturated solutions.[10] Even at the present day there are to be found some who maintain that the danger is almost a negligible quantity.[11] The case of Dr. Fountain, so well known, is an instance not so much of individual rashness as of the singular variability of the action of potassic chlorate. It will be remembered that he died from the effects of taking an ounce, a quantity as we have seen, that was frequently taken without harm. This case, together with one reported in Germany in 1878, were thought the only two recorded.[11]

As an explanation of that variable quantity—the toxic power of a salt—it has hitherto been found useful to employ the term "idiosyncrasy." In a negative way, this hypothesis has been of use in enabling us to describe a latency of poisonous power in a chemical body—a latency exploding into virulence under given circumstances. Latterly this idea has expanded into the notion of the pharmacodynamics of a salt, namely, the power it possesses as an entity, that is, before its molecular structure has been changed. These pharmacodynamic effects, according to Gruetzner, are proportionate—not to the absolute weight of a salt, but to its molecular weight.[12] It is, therefore, instructive to note that potassic chlorate acts in a state of almost complete molecular integrity, as it passes practically unchanged through the body; and, judging from the way in which it develops a toxic strength, it seems likely that its molecule is endowed with an uncommon potentiality, for its pharmacodynamic effects are often irresistibly sudden and fatal. This sudden explosiveness of poisonous power is to be clearly seen in the cases where the salt has been merely used as a gargle and has caused death. On this postulate of its latent danger it is possible to rest a good case against potassic chlorate; and on this basis of fact it is possible to reason out the tangle of results protocoled in the "casuistik" of the experimental pathology.

In this field a wide divergence of opinion reigns. Laborde, for example, denies that intravenous injections of potassic chlorate, even in large amounts, have any effects worth mentioning. Stokvis holds that it is of no greater power than common salt, and that it in no way alters the blood elements. This proposition is true of the action of solutions, both isotonic and hyperisotonic.[13] This view is opposed alike to common sense and to a conclusive clinical experience.[14] Yet it seems to be a fairly well-established opinion among laboratory experts. Thus Riess and Bokai[15] were unable to find the absorption bands of methemoglobin in the spectroscopic analysis of the blood of animals poisoned by potassic chlorate; nor was there any ocular proof of blood changes, such as chocolate discoloration, etc. On the other hand, in cases of poisoning in the human subject, the "striæ" of both methemoglobin and hematin have been spectroscopically demonstrated, and what is more, during life.[16] In fact, no one of any practical experience can doubt that potassic chlorate may profoundly alter the composition of the blood. What an abundant clinical experience now shows is, that this alteration of the blood may take place suddenly, and after comparatively small doses. In several instances a small dose, when taken on an empty stomach, has caused death. It shows its utmost power under these conditions, viz., where there is no mechanical interposing agency (such as food, aqueous contents of the stomach) between the salt and the avenues into the blood. It is under these conditions, as any valid observation will show, that potassic chlorate may display a treacherous power.

Importance of the Tongue in Diagnosis.—The old notion that the condition of the stomach lining was reflected in the mucosa of the tongue has been long exploded and even the débris have been scattered to the winds by a communication in the *Gazette des Hôp.* of Sept. 17, 1903, in which Mathieu and Roux discourse on the diagnostic value of the state of the tongue in affections of the digestive tract. They establish that the mucous membrane of the tongue is a false mucosa. It is not formed from the inner layer, but from the outer layer of the blastoderm. In structure it resembles the skin. The "coated tongue" is not due to an actual coating, but is, in effect, a grass plot of long and thick filiform papillæ, and the white color is due to a superficial desquamative dermitis. This dermitis arises and subsides under the influence of external and internal intoxications, like any cutaneous affection, with the important difference that the tongue is much more intensely sensitive than the skin, owing to its wealth of nerves and vessels. This lingual dermitis is, therefore, an extremely early and important sign of internal derangement, and thus the tongue retains all its old diagnostic value. The only difference is that the knowledge that this dermitis may persist after the cause has subsided should suggest that we must not wait for the tongue to clear before instituting nourishing feeding.

CERTAIN PHASES OF THE MILK PROBLEM.

There are few problems in medicine to-day which, from the point of view of the practicing physician, approach in importance the milk problem. The tendency of modern medicine is toward prevention of disease rather than cure. This does not mean that the treatment of disease is considered less important to-day than formerly, but rather that, through the application of the revolutionizing discoveries made in relation to infectious diseases, it has become possible to directly attack the disease from the standpoint of etiology, an attack seldom possible before, for causative factors were so little known.

Milk, being an excellent food both for man and bacteria, furnishes a most striking source of danger, because of the possibility of its being contaminated with pathogenic germs; and since it is so universally used, and especially because it is so indispensable to the young susceptible infant, it becomes plain at once that we have here an excellent problem for the application of the principles of preventive medicine. The frightful infant mortality in our large cities during the summer months, due in a large measure to unwholesome and contaminated milk, is sufficient to stimulate our best efforts to remedy this evil. Education of the people and of the dairymen can do much. A rigid system of inspection properly conducted might accomplish a great deal. But with our ever-increasing centers of population requiring milk to be transported long distances, often passing through several hands, the problem of a pure milk supply becomes one of extreme difficulty, especially when operated on a purely commercial basis. Right here we may take this opportunity to congratulate the Chicago Milk Commission, which last summer carried on with such evident success the pure milk campaign in the heart of a large city, and we earnestly hope that the same work will be continued and extended during the coming season in this and other cities.

But there are other aspects of the milk problem which, perhaps, are not so familiar, and which should be more generally known, especially among physicians. It is a deplorable fact that the percentage of mothers who nurse their babies is decreasing as civilization advances—certainly not a very clear index of progress. C. von Bunge, in a recent article, states that this fact is supported by numerous reliable statistics. He asserts that this inability on the part of mothers to nurse their children is a mark of degeneration, and is hereditary. The physician at once is presented with the difficult task of finding a substitute for mother's milk. In so doing he should know first of all that a perfect substitute can not be obtained. The first difficulty which usually arises is that of obtaining fresh, clean cow's milk, free from contamination with harmful bacteria and their products. The pasteurization of milk has done much in obviating this difficulty, but the pasteurized product is not always easily obtained.

Next is the difficult problem of so altering the percentages of proteids, sugar, fats, salts, etc., in the cow's milk as to make it conform as nearly as possible to the composition of human milk during the different periods of lactation. Fortunately the solution of this difficulty has largely been overcome, and for this we are indebted principally to American medicine, chiefly through the work of Rotch, Holt, Gordon and others.

But there is still another difficulty which is not so easy to master. It has long been known that the proteids of cow's milk are not exactly the same, especially in their physical properties, as those of human milk. This is clearly shown by the appearance of the curd formed in cow's milk and human milk. Also the fact that the proteids can be thrown down by specific precipitins which have no effect on milk of animals of another species, indicates a difference in the properties of the nitrogenous constituents. It has recently been shown, too, that there are certain specific enzymes or ferments in milk which differ according to the animal from which the milk is obtained. These ferments undoubtedly have an important action on the subsequent digestive processes in the intestinal tract of the child. Jolles[1] found, for example, that human milk would split up five or six times as much hydrogen peroxid in a given time as cow's milk, this action being due to the presence of a ferment. He also found differences in the behavior of woman's and cow's milk toward tincture of guaiac.

Welch, in his Huxley lecture, called attention to the function of mother's milk in transferring proper antibodies to the child. These bodies are absorbed by the stomach of the child in an active state, and hence we have an explanation of the greater resisting power of the breast-fed infant to infections, while the bottle-fed infant is much more susceptible. Ehrlich also has found that suckling animals can be protected from a specific disease if fed on milk from an animal which has been rendered immune.

Such facts as these furnish a scientific basis for the problem of infant feeding. They fully explain the fact already known that bottle-fed infants are at a great disadvantage in resisting disease, and they also explain the difficulty of furnishing a perfect substitute for human milk, and they emphasize the dictum: Feed the babies, so far as is in any way possible, on mother's milk.

THE LESIONS OF UREMIA.

Cellular activity underlies all function, so that derangement of the latter necessarily implies alteration in structure. This alteration may be molecular, and thus not permanent or demonstrable, but it may be of any degree to the point of organic disease obvious to the naked eye. In the group of disorders designated functional, it is certain that changes occur which escape detection only because of the inadequacy of our best means of investigation, but even this group has gradually been reduced in number by the discovery of lesions with the aid of more refined modern methods. Thus some cases of epilepsy are obtrusively dependent on organic or structural alterations, and the view is gaining ground that other cases are due to changes of only a less coarse nature. It has been shown further that many toxic processes are attended with cellular changes, which, it may be conceived, if long continued or profound, may result in structural degeneration. In fact, demonstration of this character has been made.

Of the disorders of the class under consideration, none is perhaps more interesting than uremia, and none affords a better field for histologic study. The symptoms to which this toxic process may give rise are in part general and in part local. The former include, especially, loss of consciousness and convulsions, the latter palsy, aphasia and headache. The diagnosis is extremely difficult. After death, the only macroscopic alteration in the nervous system consists in edema of the brain and its membranes. Lately, a condition of chromatolysis of cells in the central nervous system has been found.

An interesting and important contribution to this subject is made by Dr. T. H. Weisenburg,[1] who reports two cases of uremic hemiplegia attended with alterations in the nerve-cells of the brain and spinal cord, associated in one with recent primary degeneration of the central motor tract. The one case occurred in a woman, 71 years old, who was attacked with left hemiplegia, resulting in death after fourteen days. On postmortem examination a condition of chronic diffuse nephritis was found, without gross lesion of the brain or cord. On histologic study, however, advanced chromatolysis was demonstrable, especially in the Betz cells of the paracentral lobule, more distinct on the side opposite the paralysis. The cells of the anterior horns of the spinal cord, the medulla oblongata and the cerebellum also were altered, though in lesser degree. There was present further slight though unmistakable degeneration of the fibers of one motor tract, from the lumbar cord to the internal capsule, evidently of recent origin. The degeneration was most marked in the left crossed pyramidal tract in the cervical region, and it became less intense in the medulla oblongata and the cerebral peduncle, while only traces of it could be detected in the internal capsule.

The second case occurred in a woman, 77 years old, also with left hemiplegia, terminating fatally in the course of four days. After death chronic diffuse nephritis was found, without gross change in brain or cord, although histologically degenerative changes were demonstrable in the nerve-cells, without, however, any alteration in the motor tract.

The evidence furnished by this report, and by others of like character in the literature, both clinical and experimental, render it certain that the uremic poison is capable of causing destructive changes in the cells of the central nervous system, especially the motor cells, and that degeneration of the motor tracts may follow as a result. It is further reasonable to conclude that what is true of uremia is probably equally true of other toxic processes.

ANTITOXINS IN PURE FORM.

During the last few years our knowledge concerning the nature and working of antitoxic serums has advanced so rapidly that it is only with difficulty that one can keep up with the new facts that are coming to light on all sides. Ehrlich's side-chain theory has furnished us with a good working hypothesis on which to advance, and with its aid we can form a clear mental picture of the mechanism of the production of antibodies. We know also through Ehrlich's teaching that the neutralization of toxin by antitoxin is a chemical reaction, and efforts are being made to show that this reaction follows the same laws that are known to govern the simpler and better understood chemical phenomena. The nature of some bacterial toxins has also been studied in great detail, and attempts have been made to make an equally close study of the antitoxic bodies found in the various antitoxic serums. The great difficulty here has been to free the antibodies of the serum-albumin and serum-globulin with which they are so intimately mixed.

Pick, however, has made great advances toward getting the antibodies in pure form by making use of Hofmeister's method of fractional salting out of proteids. According to this method, the serum-globulin is divided into (1) fibrinoglobulin, which is precipitated by a small percentage of ammonium sulphate; (2) euglobulin, which is precipitated by adding one part of a saturated solution of ammonium sulphate to two parts of serum; and (3) pseudoglobulin, which is precipitated only by half saturating the serum with ammonium sulphate, the albumin still remaining in solution. Pick found now that the fibrinoglobulin and the albumin possess no antitoxic properties, while either the euglobulin or the pseudoglobulin contains all the antitoxin. Which one of these two globulins contains the antitoxin depends on the kind of animal from which the serum is taken, whether a horse or a goat, and on the kind of toxin used in the process of immunization, whether from diphtheria, tetanus or cholera cultures. He found, for instance, that the diphtheria and tetanus antitoxins in horse's immune serum are precipitated with the pseudoglobulin, while these same antitoxins in goat's immune serum are precipitated with the euglobulin. This is very interesting, because it points to the probability of there being a fundamental difference between the several antitoxins, although they seem to act alike when injected into an infected animal. The specific agglutinins in typhoid and cholera immune horse's serums may also be precipitated with ammonium sulphate, and the interesting fact has come to light that the cholera agglutinin goes down with the euglobulin, while the typhoid agglutinin comes down only with the pseudoglobulin. In the goat's and rabbit's immune serums both of the agglutinins are contained in the euglobulin. The precipitin in typhoid immune horse's serum is contained in the euglobulin, thus differing from the agglutinin for the same organism. Rodhain made a study of antistreptococcus serum from a horse, and found that both the antitoxin and the agglutinin are precipitated with the euglobulin, thus differing from the diphtheria and tetanus antitoxins, which, in horse's serum, are found in the pseudoglobulin.

---

[1] Proceedings of the Pathological Society of Philadelphia, February, 1904, p. 62.

Although the antibodies have been freed from a large portion of the proteids, it can not be said that they are identical with the globulins with which they are precipitated. In fact, there is evidence to show that they are not globulins, but as yet no satisfactory scheme has been published for getting them in pure form, although Pröscher states that he has succeeded in freeing them from all proteids. By means of this fractional salting-out method, the antitoxin can be prepared in a much more concentrated form, and the inert substances which have no therapeutic value need not be thrown into the patient's system, which is already overloaded with work.

THE PANAMA CANAL COMMISSION AND MEDICAL SERVICE AT THE ISTHMUS.

A recent news item announces that the Panama Canal Commission has sailed for the isthmus on a tour of inspection. Accompanying the commission were Drs. William C. Gorgas and Louis LaGarde of the United States Army and Dr. Ross of the Navy, who, it is unofficially announced, are to have supervision of the sanitary arrangements on the isthmus.

The circumstance, in all its aspects, is one of decided interest to the medical profession of America. In the first place, the commission, made up of a soldier, a sailor, four engineers (designated by law) and a railroad man—all of them, however, eminent in their respective callings—had evidently no sooner accepted their instructions from the President than they found themselves confronted by the sanitary problem, the fundamental difficulty underlying the whole enterprise. As a matter of fact, the President himself, who had previously received over fourteen hundred telegrams and a large number of letters on the subject from physicians all over the United States, went quite as far as he could in telling the commissioners that they must have first regard for the health problems, going so far even as to intimate that that department would better be placed in the hands of one man specially fitted to meet its responsibilities. That the commissioners have or have not acted on this very wise advice can not be determined from any intimation that has so far been vouchsafed to the public. It is evident, however, that, confronted with responsibilities that they knew they were technically unqualified to meet, they had no sooner taken their last sip of coffee at the White House luncheon, by which they were inducted into office, than they sent up a Macedonian cry for Colonel Gorgas—the very man whom the medical profession had been urging for appointment on the commission. This was a hopeful beginning. The addition of Drs. LaGarde and Ross to the medical advisory bureau—for, in the nature of things, it will not be permitted to be more than advisory—will even strengthen the extemporized medical corps, unless in violation of correct principles of organization it is thereby made a hydra-headed monster.

The more plausible inference—for as yet we are permitted only to infer—is, however, that Colonel Gorgas is to consider the land sanitation, Dr. Ross that relating to sea transportation, while Dr. LaGarde is to study the question from the more strictly military view point. This seems very natural, and doubtless will do very well if several questions that can hardly be called subsidiary are properly solved. Thus if, in the organization of the sanitary forces, these three apparently coordinate branches are made really to co-ordinate, the circumstance must be considered fortunate; if, on the other hand, each is made independently autonomous, no prophetic vision is required to foresee disaster. But the question naturally arises, where is to be the co-ordinating center? This, under the law, can exist nowhere else than in the commission itself. Thus we find this very respectable body of laymen, in spite of any regulations that they may frame, called on to sit in final judgment on questions foreign alike to their schooling and their experience. If they attempt to shift the responsibility by regulations they are still responsible for the regulations, to the general provisions of which all practical details must be made to conform.

It follows, as a consequence, that the medical profession, while placed in a position of primary accountability for results in the most conspicuous enterprise of the century, if not, indeed, of the centuries, is, nevertheless, without representation in the council that orders, directs and absolutely controls every action. This attitude of distinct subordination—an attitude that can not be otherwise than offensive to every self-respecting physician in the United States—is one for which Congress, by failing to specify that at least one medical man, as well as engineers, should be on the commission, is to be held responsible.

A DELICATE TEST FOR ARSENIC.

We again call attention to the interesting researches of Abbo, the director of the Hygienic Institute of Turin, on the detection of minute quantities of arsenic by means of the growth of a certain variety of fungus. This fungus, known to botanists as *Penicillium brevicaule,* was long since observed as a frequent and troublesome growth on the walls of damp rooms covered with paper containing arsenic. But it is only recently that it has been established that the fungus, when brought into contact with substances containing arsenic, develops with great rapidity an intense odor of garlic.

Abbo, as a result of a long series of experiments, now recommends the use of the fungus as the simplest, surest and most delicate qualitative test which exists for the presence or absence of arsenic. He has found it possible to establish definitely within a few hours the presence of minute quantities of arsenic in a contaminated flour, in the urine of patients treated with arsenical preparations, and even in a case of arsenic poisoning through illuminating gas. Abbo's assertions receive strong support in the confirmatory work of Abel and Battenburg in the Hygienic Institute at Hamburg.

The reaction for arsenic by means of *Penicillium brevicaule* is said to be so sharp that even as small an amount of the substance as one-millionth part of a gram can be detected. Obviously, here we have to deal with a delicacy of reaction which is almost unprecedented. It is of great interest that the degree of refinement in the test attained is dependent on the sense of smell, for it is by aid of the olfactory sense that even smaller amounts of certain organic substances can be made out. Thus Emil Fischer and Pentzold have shown that one five-millionth of a gram of chlorphenol can be perceived by the nose, and even a smaller quantity of mercaptan can be recognized by it. Of course, such quantities are far removed from the weight of a chemical molecule; they represent, according to present estimates, at least from two hundred millions to several billions of molecules. Nevertheless, such olfactory reactions are far more delicate than ordinary optical tests.

The "arsenic-fungus" grows well on potato, and can be kept in pure culture, without transplantation, over a long period; there seems to be no reason, therefore, why the test should not be frequently applied, even by the physician in private practice. That the reaction will play an important part in legal medicine there can be no doubt. No less an authority than Professor Kobert holds the discovery of the arsenic-fungus to be one of the greatest of modern victories for forensic medicine.

COMMISSION TO MEDICAL SOCIETIES.

A new form of commission evil comes to light. An enterprising firm imbued with the spirit of the age (at least that portion of it denoted as "grafting"), has made a novel proposal to the secretaries of state medical associations. We quote:

> We are sending you by mail a display card with booklet on the ——— ——— ———, which we would kindly ask you to have displayed in any prominent place at the meeting, either in the Assembly or Exhibit Hall where physicians who are interested in the treatment of ——— may see the same; for which courtesy we will send the association or you a draft for five dollars ($5.00) on the first order received from any ——— surgeon or hospital following the meeting.

A smirking pretense of regard for the proprieties is shown in the half-hearted proposal to donate the remuneration to the association in case the secretary has a conscience.

INHERITED DEFORMITY.

In the Vienna correspondence of the *Medical Press and Circular,* March 12, it is reported that Dr. Heim presented before the medical society at Vienna (*Gesellschaft der Aerzte*), a woman aged forty, who twenty-one years before had suffered from injury and blood poisoning of the right middle finger, which necessitated two years later amputation of the finger with the third metacarpal bone. Since then she has had six children, four of whom have had cloven hands shaped in the same manner as their mother's, with, in some cases, a rudimentary third metacarpal bone. Heim also gave a history of a similar condition existing in three generations in another case. Considering the fact that the inheritance of acquired characters is a matter of dispute and is positively denied by a large school of medical writers, such reports as these are deserving of a thorough investigation. They are in accordance with the popular belief, but the satisfactory evidence of their occurrence is not often complete or forthcoming. We trust that this case will be thoroughly authenticated or disproved, and the relation of the original injury to the inherited defect be, if possible, adequately traced out.

TITLES OF PAPERS.

One of the interesting features of the editor's work in looking over other medical journals is to note the varieties in titles and the peculiarities of authors. The titles of some articles are so long that they almost make it unnecessary to read the paper. Harris Hawthorne Wilder, in a letter to *Science,* March 18, comments interestingly on long titles, which he classifies as "explanatory" or as "modest." In the first, an author endeavors to show exactly what he is covering in his paper; in the second, he seeks to bring out that he appreciates the vastness of the subject and how little he really has accomplished. One of the latter often begins, "A contribution to the study of." Wilder says that although composed in the most laudable spirit, such titles are hardly necessary, since there is little danger of misunderstanding on the point guarded against by the writer. Wilder suggests the use of a title and a subtitle. This is a plan we often use in The Journal, making the title brief and general, and including in the subtitle certain definitions and limitations of the subject. We are amused by the title at the head of Wilder's communication, but we do not know whether he or the editor of *Science* is responsible for it. It is "On Titles for Papers." What possible use the word "on" may have is unknown to us. There is often much room for improvement in titles, and the elimination of unnecessary words is one means of improvement.

THE OCCURRENCE OF TYPHOID BACILLI IN THE EXCRETA OF TYPHOID CONVALESCENTS.

The importance, from a prophylactic point of view, of knowing how long the typhoid bacillus may remain in the excreta can not be overestimated. As far as the urine is concerned there have been numerous observations in the past few years, which have led to an appreciation of the fact that the typhoid bacillus is present in the urine in a fair percentage of typhoid cases, and that it may remain even years after convalescence has been established. Herbert[1] has recently been able to study both the urine and the feces in a large number of convalescent typhoid patients during an epidemic in a hospital for the insane. The urine of ninety-eight convalescents was examined, and the typhoid bacillus was found in eighteen or a little over eighteen per cent. of the cases. In the same number of cases typhoid bacilli were only found in the stools three times, a little over three per cent. An interesting fact in connection with the urine examinations was that the bacilli appeared intermittently in one case. They would disappear for a few days and then reappear again, often in large numbers. The important practical fact shown by these investigations is that the urine of convalescent typhoid cases is much more dangerous than the feces, and should be most carefully disinfected in all cases until the bacilli disappear.

NEW IMMUNITY TERMS.

"Antitrope," or "antitropin," is a new term which Wright[2] has invented as a generic term for the antibodies. Aside from the fact that it is undesirable to introduce a multiplicity of terms to designate the same thing, we are inclined to consider the word itself a poor one. The use of *anti-* is appropriate in two senses; it expresses, in the first place, the antagonism which an antibody has for its counter-substance, and suggests also the general law that by immunizing with proper proteid bodies there are developed new bodies the specific opposites of those injected. The term antibody seems, then, to express the important qualities in a generic sense. The addition of *-trope* or *-tropin* (from the Greek τρεπειν, to turn) introduces the idea of affinity into a word which already bears the meaning of antagonism. Either root may be considered as appropriate, but the two combined add nothing essential to the already established *antibody*. Through its use Wright has provided us with the following combinations: agglutinating, bactericidal, bacteriolytic, antitoxic, and opsonic antitropins. "Opsonin" is used to designate that quality of a serum which makes a microbe more susceptible to phagocytosis, the term having its origin from a Greek word which means "to provide food for." It is questionable if such a quality of serum, as a distinct one. has been sufficiently determined as to justify our looking at it in this specific manner. It may well be that the bactericidal substances, or in some cases the agglutinating, so impress the bacteria that they become more readily the prey of the phagocytes. Hence, until opsonin can be demonstrated as a substance distinct from these, the word does not commend itself for general use.

THE PASSING OF THE CORONER.

After four years of strenuous effort the Elsberg bill abolishing the office of coroner in Greater New York has been passed, its passage having been materially aided by an emergency message from the governor. The bill does not affect the coroners now in office, but no successors will be elected. The only powers that remain to the coroners are those of investigation. They may collect evidence and take testimony to aid the magistrate and district attorney. In addition to the valid reasons which have been previously given in The Journal for the passage of such an act, there will be a saving in New York City of not less than $60,000 per year, beside putting an end to the ignorant and corrupt practices which have grown up under the late evil system. Some of the political coroners, it is said, have been unable to speak intelligible English, and miscarriages of justice have occurred on this account. How deeply this lon-continued abuse had established itself is evidenced by the fact that the bill was introduced and beaten in four legislatures before its final passage. Under the present law there is provided a chief medical examiner and six medical examiners for Manhattan Borough, four for Brooklyn, three for Queens and two each for the boroughs of Bronx and Richmond. They are to be physicians appointed by the mayor, as far as practicable, from the coroners' physicians now in office. The medical examiners are to form a part of the health department, their duties being to make reports in all suspicious deaths to the magistrate, and if the examiner is not satisfied with the result of the examination as to the cause of death he is to invite the district attorney, and then make an autopsy in the presence of that officer and of a policeman. The people of the city of New York are to be congratulated on the departure of this antiquated relic of monarchical government.

A PLEA FOR PATHOLOGIC PHYSIOLOGY.

The remarks of Professor Orth, chairman of the *Deutschen pathologischen Gesellschaft*, at its last meeting in Cassel, in which the desirability of cultivating pathologic physiology in contrast with pathologic anatomy was strongly emphasized, have just been published in full.[2] It was a favorite idea of Virchow's, though Virchow himself was a pathologic anatomist, that the science of pathologic physiology should be developed; such a science includes the essence of practical medicine. for the latter is only applied theoretical medicine, that is, pathologic physiology. Pathologic physiology is founded on pathologic anatomy, clinical observations and experimental investigations; it has as its task the establishment and explanation of the vital processes under abnormal conditions. It is a biologic science, standing in the same relation to pathologic anatomy as that in which normal physiology stands to normal anatomy. It is necessary to admit, as Professor Orth does, that the development of pathology thus far has been predominantly along morphologic lines. Clinicians have, it is true, made notable contributions to the pathologic physiology of man; much more perhaps can be hoped from them when universities establish clinical chairs with honoraria large enough to absolve the holders from the necessity of making a living from private practice, permitting them to devote more of their time and energies to the scientific side of their work. But experimental pathologic biology is the branch which, perhaps, more than any other needs attention just now. It is matter for regret that by far the majority of chairs of pathology in this country and in Germany are devoted to work in pathologic anatomy, to the exclusion of pathologic physiology, except, perhaps, as a side issue in some of the laboratories. An ideal department of pathology should provide for teaching and investigation in experimental pathologic physiology, as well as in pathologic anatomy. We do not wish to see the autopsy table and the microtome banished from our laboratories of pathology; quite the contrary. Let them be forced to yield us what information they will. But, in addition to our morphologic pathologists, we need a generation of young pathologists, trained in mathematics, physics and chemistry, who will approach the study of disease and its phenomena from the functional rather than from the morphologic side. Possibly progress might more rapidly be made in this direction if some of our stronger and wealthier universities were to establish special chairs for experimental pathologic physiology.

THE RADICAL CURE OF HERNIA.

There seems no reason now why patients, and especially young patients, should any longer be discouraged from having radical operations for hernia done, and encouraged to wear trusses with all the danger and inconvenience and discomfort that this form of treatment entails. There are still many physicians, however, who seem to feel that operation should not be suggested, and who perhaps have not fully realized what is the present position of surgery in this matter. In the last number of the *International Medical Annual*,[1] Dr. Mayo Robson, the distinguished English surgeon, reviews the statistics of a number of operators for the radical cure of hernia, and shows very clearly how favorable have been the results immediate and eventual of operation. In Johns Hopkins Hospital there was only one death in 459 operations. In Carle's clinic in Rome, two deaths in over 1,400 operations. In the Vienna clinic, three deaths out of 804 operations. In Dr. W. B. Coley's 1,075 cases only two deaths. All of these reports combined give a mortality of scarcely one-fifth of 1 per cent. In spite of ominous prognostications from older surgeons, the ultimate results in the majority of cases are even better than have been anticipated by the advocates of early operation. Out of 917 Bassini's operations not quite one out of every 100 cases suffered from a relapse of the hernia, though many of the cases were old and complicated. When relapse does occur, it comes within six months almost without exception. Patients who remain cured for a year after the operation, may be expected to continue in this condition, and after two years may be considered permanently cured. This is an excellent result to obtain at so slight a risk. An analysis of the cases in which death occurs would still further enhance the encouragement afforded by the statistics, since many of the fatalities were due not to septic infection nor to any mishap during the operation, but to conditions like the effect of anesthetics or of kidney irritation, which could not well be foreseen and guarded against. When the very high mortality of strangulated hernia is considered, the picture thus presented becomes even still more striking. At the present time in hospital practice more than one out of every five patients are lost, even in the hands of excellent operators. In private practice the mortality is less than 10 per cent., but this is surely not low enough to encourage the taking of the risk. There seems no doubt, then, that physicians should recommend much more generally than they do at the present time the radical cure of hernia by operative procedure rather than, as is commonly done, prescribe a truss. The smaller the hernia the more easily the operation is performed and the less danger there is of recurrence. It is after tissues have become weakened and deformed by the frequent protrusion of the hernial sac that the operation becomes more dangerous and relapse becomes more possible. Here that much-abused term, conservatism, seems to indicate operative intervention rather than the supposedly palliative, but in many cases really provocative, treatment by apparatus.

Medical News.

CONNECTICUT.

For the Endowment Fund.—Under the will of the late Mrs. Anna Sophia Farnum, the endowment fund of the Yale Medical school receives the income of $50,000.

Shoemaker Lectures at Hartford.—The third lecture in the course at Walnut Lodge Hospital, Hartford, was delivered by Dr. John V. Shoemaker, Philadelphia, who spoke on "The Abuse of Drugs."

Talks on Tuberculosis.—Popular lectures have been given in New Haven under the auspices of the local medical association, on the "Prevention and Cure of Consumption," by Dr. Louis M. Gompertz in English; by Dr. Nicola Mariani in Italian, and by Dr. Polinski for the benefit of those who understand neither English nor Italian.

GEORGIA.

Smallpox.—Smallpox is reported to be raging at Babcock, about eight miles from Colquitt.

Commencement.—Atlanta College of Physicians and Surgeons, at its commencement exercises, March 29, conferred diplomas on a class of 43.——On April 1 the Medical College of Georgia, Augusta, graduated a class of 22.

Personal.—Dr. John A. Corry, Barnesville, has been made local surgeon of the Central Railroad of Georgia, vice Dr. K. Lowder Reid, removed to Atlanta.——The Valdosk Board of Health has organized with Dr. Benjamin S. Burton, president, and Dr. James M. Smith, vice-president.

ILLINOIS.

Pure Food Bill.—Peoria County Medical Society, at its last meeting, adopted resolutions favoring the adoption of the Heyburn pure food bill.

Promotion.—Major Henry Richings, Rockford, surgeon Third Infantry, Ill. N. G., has been appointed assistant surgeon general, and chief surgeon of the Third Brigade with rank of lieutenant colonel.

Physician a Fugitive.—Dr. Benjamin F. Slusher, Decatur, who was indicted by the Macon County grand jury, charged with the death of a woman by a criminal operation has disappeared, and the governor has offered a reward of $200 for his apprehension.

Chicago.

New Internes.—Of the new internes at Cook County Hospital, 8 are graduates of Rush Medical College, 4 of Northwestern University Medical School, and one of the College of Physicians and Surgeons.

Evans for President of State University.—The name of Dr. William A. Evans is the one most prominently brought before the profession and public thus far, as successor to President Draper of the University of Illinois. The medical profession, which knows Dr. Evans well, is most active in urging his candidacy.

Pneumonia on the Decrease.—The 111 pneumonia deaths of the week represent but 18 per cent., instead of the previous average of 21 per cent. of the total deaths. There is a similar decline in New York. The following are the figures for the two cities during the current pneumonia season, from Nov. 1, 1903, to April 16:

	New York.	Chicago.
Total deaths, all causes	36,831	13,586
Deaths from consumption	4,128	1,423
Deaths from pneumonia	7,769	2,968
Proportion per cent. of all deaths—		
From consumption	11.2	10.4
From pneumonia	21.1	21.8

The Deaths of the Week.—With the exception of the acute intestinal diseases, Bright's disease and pneumonia, all the important causes of death show an increase in the returns for the week. The total of 616 is 54 more than the total for the previous week, but is 24 less than for the corresponding week a year ago. In proportion to population this is 8 per cent. per 1,000 more and 7 per cent. per 1,000 less for the respective weeks. As compared with the average April death rate of the previous decade—17.31 per 1,000—it is 4.8 per cent. less. Pneumonia leads with 111 deaths; then follow consumption with 78; heart disease with 50; violence with 43, and Bright's disease with 39 deaths.

INDIANA.

Smallpox.—At Aetna Green, Kosciusko County, there are about 60 cases of smallpox. Vaccination is in progress and close quarantine is enforced.

Hurty Re-elected.—The Indiana State Board of Health has unanimously re-elected Dr. John N. Hurty, Indianapolis, as secretary of the Board for a term of four years.

March Deaths.—During March 3,487 deaths occurred, an annual rate of 17.4 per 1,000. In the corresponding month of 1903, 2,677 deaths were reported, an annual rate of 13.8 per 1,000. Pneumonia caused 711 deaths, as compared with 399 in March, 1903.

Fire in Indianapolis Hospital.—Fire in St. Vincent's Hospital, Indianapolis, early on the morning of April 17, caused one death, that of an aged nurse, who jumped from a fifth-story window; necessitated the removal of about 200 patients, and caused a loss of $2,000. Further casualties were avoided by the presence of mind and heroism of Miss Hannah Heaken, a nurse, and of James Dawson, a patient.

Personal.—Dr. Ira E. Dunlavy, Indianapolis, has been appointed first deputy coroner of Marion County, vice Dr. John F. Geis, deceased.——Dr. and Mrs. Leo J. Weinstein, Terre Haute, have taken a trip to Bermuda.——Dr. Stanley W. Edwins, Elwood, has retired from active practice.——Dr. and Mrs. Edmund D. Clark, Indianapolis, sailed for Italy, April 12.——Dr. Sarah Stockton, Indianapolis, has been appointed a member of the State Board of Charities and Corrections.——Dr. William E. Green, Hanover, had his arm broken and sustained internal injuries in à runaway accident.

MARYLAND.

Will Build Hospital Wing.—Mrs. Margaret E. S. Hood, a member of the board of directors of the Frederick City Hospital, will erect a wing to the hospital as a gift, to cost about $8,000.

Governor Signs Bills.—The governor has signed the following additional bills: Tuberculosis commission; abolishing Allegany Insane Asylum; restricting sale of narcotic drugs: omnibus appropriation bill, appointing five police surgeons for Baltimore; appropriation for state Board of Pharmacy; regulating practice of medicine and registration of nurses.

Baltimore.

Cecil Rhodes Scholarship.—Twelve candidates appeared last week at the Johns Hopkins University to compete for the one Cecil Rhodes scholarship at Oxford University allowed this state. The successful candidate will receive three years' tuition at Oxford and $1,500 per annum. He can pursue in his discretion a collegiate, post-graduate or professional course.

Personal.—Dr. William Hewson Baltzell leaves for Europe, April 29.——Dr. H. M. Cohen sailed for Europe April 20.——Dr. Harry C. Jones of the chemical department of Johns Hopkins University, has received $1,000 from the Carnegie Institute for research work in physical chemistry. He has appointed Dr. H. P. Basset research scholar.——Dr. Thomas H. Buckler will spend the summer at Northeast Harbor, Maine.

Ehrlich on Immunity.—Dr. Paul Ehrlich lectured on immunity, April 12, 13 and 14. On Tuesday evening a smoker was given in his honor at the Maryland Club, and on Wednesday evening a dinner by the Medical Faculty of Johns Hopkins University. There were about 60 present from Baltimore, New York, Philadelphia and Washington. At the close of Dr. Ehrlich's last lecture, Dr. William H. Welch addressed him in a complimentary speech in his own language.

Health Report.—Ten new cases of smallpox were reported in Baltimore last week, making 19 now at quarantine. There are 19 suspects at the detention barracks. The cases recently discovered have been scattered through the city, showing that they were of local development, and that the contagion has obtained a foothold here. The total deaths were 191, or 17.69 per 1000 per annum; consumption causing 31, pneumonia, 19; heart disease, 16; Bright's disease, 14, and typhoid fever, influenza, and scarlet fever, each 5.

MICHIGAN.

Lower Michigan Should Boil Water.—The State Board of Health has issued a bulletin urging that all drinking water in lower Michigan be boiled on account of recent floods, by reason of which there has been much surface drainage into wells.

Buys College Property.—The Medical College Equipment company of Grand Rapids has been incorporated with a capital stock of $1,500, to acquire the property of the Grand Rapids Medical College and has leased the property to the trustees of the college.

Wooden Anniversary of Biologic Department.—The Stearns laboratories, Detroit, celebrated the fifth anniversary of their establishment, April 7. Unique wooden invitations were issued and several hundred physicians took occasion to visit the laboratories and observe the work in progress there. A buffet luncheon was served and wooden souvenirs were distributed.

Comparative Morbidity.—For March, 1904, compared with the preceding month, cancer, smallpox, cholera morbus, meningitis, membranous croup and puerperal fever were more prevalent; and syphilis, typhoid fever, intermittent fever, and dysentery were less prevalent. For the same month, compared with the average for March in the previous ten years, 1894-1903, scarlet fever, typhoid fever, smallpox, and diphtheria were more than usually prevalent; and pneumonia, erysipelas, inflammation of bowels, intermittent fever, remittent fever, whooping cough, dysentery, cholera morbus and puerperal fever were less than usually prevalent.

The Most Dangerous Communicable Diseases.—Meningitis was reported present during March, 1904, at 10 places; whooping cough at 22 places; diphtheria at 81 places; typhoid fever at 82 places; smallpox at 138 places; measles at 152 places; scarlet fever at 162 places; pneumonia at 166 places, and consumption at 233 places. Meningitis reported present at the same number of places: whooping cough at 2 places more; diphtheria at 16 places less; typhoid fever at 5 places less; smallpox at 7 places more; measles at 23 places more; scarlet fever at the same number of places; pneumonia at 57 places more; and consumption at 26 places more, in the month of March, 1904, when compared with the preceding month.

March Mortality of Michigan.—The total number of deaths for the month of March was 3,406, which was only 19 more than the number returned for the preceding month. The death rate was 16 per 1,000 population, as compared with 17.1 for the preceding month. Important causes of death were as follows: Tuberculosis of lungs, 270; typhoid fever, 57; diphtheria, 38; scarlet fever, 31; measles, 27; whooping cough, 21; pneumonia, 384; influenza, 156; cancer, 149; accidents and violence, 199. Deaths from pulmonary tuberculosis and typhoid fever showed some increase, while diphtheria, pneumonia and influenza caused considerably fewer deaths in March than in February.

MINNESOTA.

Smallpox.—During the last week of March, 62 cases of smallpox were reported to the State Board of Health. Of these, 17 were in Minneapolis, with one death.

St. Paul Physicians Win Suit.—Drs. Charles A. Wheaton, John T. Rogers and Warren A. Dennis, St. Paul, who were sued by William Henslin, for $22,500 on account of injuries alleged to have been suffered by him while under *x*-ray treatment, have been held blameless by the jury.

Half a Century of Medical Work.—On April 1, colleagues and friends of Dr. Charles F. Warner, Mankato, gave a banquet "in honor of fifty years' continuous service in war and peace in the honorable practice of his profession." Dr. E. J. Davis presided as toastmaster, and after many eulogistic toasts had been given, Dr. Warner closed with reminiscences.

St. Paul Has Little Typhoid.—The death-rate of St. Paul from typhoid fever in 1901, 1902 and 1903 is announced to have been about 16 per 100,000, less than one-third the death-rate of Minneapolis for the same period, about one-half the death rate of cities and villages between 2,000 and 20,000 inhabitants, and less than a third greater than the death-rate in rural communities in the state.

Personal.—Dr. Donald B. Pritchard, Winona, was thrown from his buggy in a runaway accident, April 6, and suffered a fracture of the leg and severe contusions.——Dr. Albert A. Ames, recently discharged on a technicality, after having been convicted of receiving bribes while mayor of Minneapolis, was again arrested April 14 on a similar charge.——Dr. Henry Hutchinson, St. Paul, has been elected president of the State Board of Health, vice Dr. Franklin Staples, Winona, deceased, and Dr. William H. Rowe, St. James, was elected vice-president.

MISSOURI.

Graduating Exercises.—St. Louis College of Physicians and Surgeons graduated a class of 46, April 12.——University Medical College, Kansas City, held its commencement exercises, April 12, and conferred diplomas on a class of 67.

How Long!—Many people near Carson have been ill with an undiagnosticated disease, pronounced by certain of the local talent to be itch. The State Board of Health has made the usual investigation with the usual result—smallpox.

Damages Against Healers.—The Supreme Court of the state has affirmed the decision of the circuit court of Bates County, which allowed $7,500 damages to Sue L. Longan, in her suit against S. A. Weltmer and J. H. Kelly, "magnetic healers," of Nevada, for criminal negligence.

St. Louis Personals.—Health Commissioner Dr. John H. Simon, who has been seriously ill with pneumonia, is now believed to be securely convalescent.——Dr. J. Mather Pfeiffenberger, has been appointed assistant superintendent of the City Hospital, vice Dr. J. S. Herrington.——Dr. Bruce Cochran, senior on the attending staff of the City Hospital, is seriously ill from septicemia due to an autopsy wound.

NEW YORK.

Epidemics.—An epidemic of diphtheria is now raging in Montgomery.——An epidemic of scarlet fever prevails in Rome, where 60 cases have been reported. Five of the public schools have been closed.

Cancer Laboratory Gets Appropriation.—The state cancer laboratory at Buffalo will receive its annual appropriation of $15,000 from the legislature. The chairman of the senate finance committee, who cut the item out, finally agreed that it be retained in the supply bill.

Personal.—Dr. Elmer E. Larkin, Plattsburg, was appointed a manager of the State Consumptive Hospital in the Adirondacks.——Dr. William Mabon, general superintendent of Bellevue Hospital, has been named president and medical member of the State Lunacy Commission. He will have a life tenure with a salary of $7,500 a year, and an allowance of $1,200 a year for traveling expenses.

Further Ratifications.—The medical associations of Wayne, Wyoming, Sullivan, Rensselaer, Westchester, Jefferson, New York, Ulster, Saratoga, Orange, Lewis, Broome and Oneida counties have ratified; a remarkable showing, as the state ratification took place only on March 25. The majority of both county societies and associations will have ratified before May. The counties that have already acted represent more than three-fourths of the entire membership.

Protection Against Blackmail.—The large number of blackmailing malpractice suits against reputable physicians led the New York State Medical Association two years ago to undertake to furnish its members with a purely fighting defense proposition, requiring the applicant for defense to agree to fight each case through to the court of last resort. The counsel for the association says that statistics show that, during the last few years, throughout the United States, one physician in every one hundred and fifty has been sued each year for alleged malpractice. The medical association, by its work, has decreased the number of these suits. In most of these cases no complaint has ever been served, and in only three has the action been put on the calendar for trial, showing that after one year of this defense an effect on the public was evident. This defense has become so well known that the whole state is covered and physicians in other cities receive the same defense as those in New York County who are members of the association. Within the last year three of the representative organizations of other states have taken up this same plan of defense.

Report of State Health Commissioner.—Dr. Daniel Lewis, in his annual report to the legislature complained of the paucity of appropriations for the work of his department. He thought $1,000,000 a year could be used with advantage to the state. He urged the enactment of a bill now before the legislature providing $20,000 for the establishment and maintenance for one year of a new bureau of water supply and drainage in the health department for the purpose of minimizing typhoid fever epidemics. The report of Dr. Willis C. Tucker, in charge of the bureau of chemistry, included in that of Dr. Lewis, showed that out of 69 samples of food analyzed 32 were found to be adulterated. As only suspected foods were analyzed the percentage of adulterated foods would probably not be so great as this. Deaths from cancer were 10 per cent. more than for the previous year. The superintendent of public instruction reported that 14.1 per cent. of the pupils examined had defective vision. Smallpox caused only 41 deaths. There were reported 89,067 births, 48,976 deaths, and 21,376 marriages. Among other important questions set forth in the report may be noted the deplorable delinquency on the part of some local health departments in reporting vital statistics; a large number of sewage systems inspected; rules for water supply protection laid down; abatement of nuisances and investigations carried on. The report of the investigators and engineers in the alleged pollution of the waters of Lake Champlain by acid sludge from the wood pulp mills will be complete in a short time.

Buffalo.

Personal.—Dr. and Mrs. T. Wright have sailed for Europe.——Drs. Edward J. Myers, Henry C. Buswell, Hal B. Brownell and Charles W. Banta sail for Europe April 23.

Serum Will Not Keep.—An effort was made by Health Commissioner Greene to have serum for the treatment of hydrophobia sent to Buffalo from New York instead of sending victims of rabid dog bites to New York for treatment. It was ascertained, however, that this could not be done, as the serum must be used within 24 hours after it is made, and that it would deteriorate under shipment.

March Deaths.—The monthly report of the department of health for March, 1904, shows an annual death rate of 15.78 per 1,000. The principal causes of death were as follows: Consumption, 45, diphtheria, 4; scarlet fever, 2; syphilis, 7; debility, 56; cancer, 33; apoplexy, 26; dementia, 14; meningitis, 16; valvular heart disease, 27; pneumonia, 60; appendicitis, 6; nephritis, 26, and violence, 30. The total deaths for March were 500, as compared with 503 for March 1903.

New York City.

Now Dr. MacDonald.—J. MacDonald, Jr., secretary and general manager of the *International Journal of Surgery*, received his diploma from the Baltimore University School of Medicine, April 19.

Stay for Dr. Conrad.—Counsel for Dr. Conrad, convicted of malpractice, have obtained from Justice Blanchard of the Supreme Court a stay of proceedings pending the hearing of an application for a certificate of reasonable doubt.

Clinic for Drunkards.—A clinic for the cure of the alcoholic habit has been established by the Salvation Army in its barracks on West Thirtieth Street for the very poorest classes. All that is necessary to gain treatment is to make known a desire to reform.

Physicians for Office Buildings.—The board of health has received communications urging the enactment of a city ordinance compelling every office building in the city, having a floor space of 50,000 square feet, to have a physician on hand at all times.

College Raises Fees.—The trustees of Columbia University will increase the annual fees for tuition from $200 to $250. The students put in a petition asking to have the proposed change made not applicable to students who had already matriculated.

Contagious Diseases.—There were reported to the board of health for the week ended April 9, 1904: 1,706 cases of measles, with 49 deaths; 474 cases of scarlet fever, with 30 deaths; 417 cases of pulmonary tuberculosis, with 200 deaths; 387 cases of diphtheria, with 70 deaths; 101 cases of varicella, 27 cases of whooping cough with 5 deaths, and 22 cases of typhoid fever, with 8 deaths. There were also 429 deaths from pneumonia, and 29 deaths from cerebrospinal meningitis.

Gift to Speedwell Society.—At the second annual meeting of the Speedwell Country Home Society for Convalescent and Abandoned Children, Mrs. Andrew Carnegie promised to equal the total of a donation to the society from other sources for the opening of a tuberculous camp within easy reach of New York City. The society asks for $100,000 in order to carry on the work of boarding convalescent children from the tenements in carefully selected country homes, as hospital experience has demonstrated that many children on their return to homes in the tenements soon sicken again and die.

Ill Treatment Alleged.—A coroner's jury has rendered a verdict that Ludwig Knacke died in the Manhattan State Hospital, March 29, from injuries inflicted in that institution. Coroner Brown held John Shea, Walter S. Reilly and Thomas H. Reilly, nurses, to the grand jury. An autopsy revealed the fact that Knacke had twelve ribs broken. At the hospital it was stated that Knacke was suffering from injuries when he was taken in. Dr. Knapp of the hospital made out the death certificate without mentioning the fractured ribs. Later, however, he amended the certificate showing fracture of the sternum and ribs.

Personal.—Dr. T. M. Cheeseman has been appointed a trustee of Columbia University to fill the vacancy caused by the resignation of Dr. Edward L. Trudeau.——Dr. George M. Lefferts, who was recently presented with a loving-cup by his clinical assistants on the occasion of his having been made professor emeritus in the College of Physicians and Surgeons, was the recipient of another loving-cup from the senior class.——Dr. William K. Simpson will succeed Dr. Lefferts as professor of laryngology.——Dr. John A. McCorkle of Brooklyn was made a member of the advisory board of the health department.

PENNSYLVANIA.

New Medical Inspector.—The State Board of Health has appointed Dr. Daniel Dechert, Schuylkill Haven, quarantine physician and medical inspector of Schuylkill county, vice Dr. Andrew H. Holberstadt, Pottsville, resigned.

Smallpox in Shamokin.—Several cases of smallpox exist in Shamokin, and the disease continues to spread. In view of this, the State Board of Health has notified the inhabitants that unless they are vaccinated it will be necessary to close the factories and collieries.

Typhoid at Lehigh University.—Several cases of typhoid fever have been reported among the students at Lehigh University. There are also a few cases in the town. The cause is attributed to the bad water. It was only a year ago that a similar outbreak occurred when at one time there were nearly 200 cases of the disease.

Philadelphia.

Examination for Internes.—The examinations for resident internes at St. Joseph's Hospital will be held May 2. Six appointments are to be made.

Ailments Exclude School Children.—The report of the assistant medical inspectors detailed to examine public school pupils show that 57,388 children were examined from April 4 to 14, inclusive. As a result, 1,111 pupils were excluded from the schools visited because of physical ailments.

Jefferson's Summer Course.—Jefferson will conduct a summer course for undergraduates and graduates in medicine for six weeks. The course will consist of practical work in embryology, normal and pathologic histology, morbid anatomy, bacteriology, and hematology, given to small classes.

Tradesmen Help Fight Typhoid.—The Trades' League, at its last meeting adopted resolutions to assist the authorities in combating typhoid fever. They will send out over 2,000 circular letters to business firms included in their membership, asking them to furnish their employes with water free from germs. The letter describes means by which the water can be rendered germ free.

Medical Club Receives.—The quarterly reception of the Philadelphia Medical Club was held April 15. Dr. William B. Ulrich, Chester, president of the Pennsylvania State Medical Society, was the guest of honor. Previous to the meeting Dr. Edward E. Montgomery, president of the club, gave a dinner in honor of Dr. Ulrich, at which were present Drs. Henry L. Orth, John B. Roberts, Francis P. Ball, and William M. Welch, all ex-presidents of the Medical Society of the State of Pennsylvania. Others present were Drs. Hobart A. Hare, Walter M. Pyle, L. Webster Fox, and J. Gurney Taylor.

Health Report.—There was a slight decrease in the number of typhoid cases reported during the week ended April 16, but still the disease prevails to a marked extent throughout the entire city, except in the two wards supplied with filtered water. The number of cases reported during the week was 359, with 29 deaths. During the previous week there were 389 cases reported and 30 deaths. There was a slight increase in smallpox cases during the week, the number reported being 25, an increase of 5 over the preceding week. The number of deaths from smallpox reported was 5, the same as for the previous week. The deaths from all causes numbered 570. This is a decrease of 27 from those of last week, and an increase of 40 over the corresponding week of last year. Deaths from pneumonia still continue high, 81 being credited to this condition; 71 were due to pulmonary tuberculosis, 46 to nephritis, and 38 to heart disease.

TENNESSEE.

Personal.—Dr. John W. Maddin, Jr., Nashville, fell from a log while fishing near Sadlersville, April 14, and dislocated his shoulder.

St. Thomas Hospital Report.—During the year 246 major operations were performed at St. Thomas Hospital, Nashville, with 3 deaths.——Dr. H. C. Brown was elected resident physician, vice Dr. William C. McCabe, term expired.

Many Graduate.—The medical department of the University of Tennessee, Nashville, graduated a class of 30, April 4.——On March 31, a class of 42 received diplomas from the University of Nashville Medical Department.——Vanderbilt University Medical Department, Nashville, held its graduating exercises, April 12, and conferred diplomas on a class of 33.——Chattanooga Medical College celebrated its fifteenth anniversary, April 4, graduating a class of 37.

Smallpox.—During the six months ended March 15 there were 3,567 cases in Hamilton County, with 70 deaths. The following counties and cities had more than 100 cases: Memphis, 443; Knoxville, 435; Knox County, 425; Union County, 250; Campbell County, 240; Monroe County, 141; Green County, 110; Shelby County, 107, and Robertson County, 106. Thirty-three counties are reported entirely free from the disease. Hamilton County still has 439 cases; Memphis, 87 cases and Knoxville, 33 cases.

TEXAS.

Held Up.—Dr. John J. Pendergrass, Leonard, was held up in his barn while getting ready to make a call, April 11, and robbed of his watch and other valuables.

State Association Meeting.—The State Medical Association of Texas will hold its thirty-sixth annual meeting at Austin, April 26-29. The house of delegates assembles April 25 at 2 p. m.

Not Dead.—Dr. William Burgess, San Antonio, after reading obituary notices of himself, announces that he was not in the Iroquois Theater (Chicago) during the fire. His obituary was, therefore, untimely and premature.

New Texas Physicians.—Dallas Medical College held its commencement exercises, April 1, conferring diplomas on a class of 25.——Baylor University Medical Department, Dallas, graduated a class of 10, April 4.——Southwestern University Medical Department, Dallas, on April 2, graduated a class of 11.

Conference at Austin.—More than 75 county and city health officers met in Austin, March 31, at a conference called by State Health Officer Dr. George R. Tabor, Austin, to take concerted action to prevent the invasion of yellow fever into Texas. Dr. Tabor urged uniform action in the work of disinfection and thorough sanitation. The conference adopted as a whole the regulations approved at the recent meeting of the Gulf States Health Conferences.

VERMONT.

Hospital Bequest.—Under the terms of the will of the late Wilbur F. Bramen, Montpelier, Heaton Hospital, in that city, is a beneficiary to the extent of about $30,000.

New Hospital at Proctor.—The new marble, steel and concrete hospital at Proctor, erected at a cost of $35,000, and presented to the town by the Vermont Marble Company was formally opened, March 26, and began to receive patients a few days later. The new building will accommodate about 18 patients.

Dr. Grinnell Wins Suit.—Dr. Ashbel P. Grinnell, dean of the medical department of the University of Vermont, Burlington, who sued Edward W. Western for $50,000 damages for arrest and false imprisonment, has won his suit, and the jury will pass on the amount of compensatory damages to which he is entitled.

Beginning of State Tuberculosis Hospital.—The $10,000 appropriated by the last legislature to construct a building for segregation of tuberculous insane patients, from the main body, is to be devoted to the erection of a two-story building, which will accommodate 22 patients, and to which male patients will be assigned.

GENERAL.

Large Tetanus Mortality in Manila.—The November, 1903, report of deaths in Manila, shows that 58.5 per cent. of all deaths and 65.5 per cent. of the deaths among Filipinos were of infants less than one year of age. There were 404 deaths among children under one year; their causes are variously reported as convulsions of children, eclampsia and tetanus. The board of health calls attention to the fact that the more prominent symptoms presented by these three causes largely resemble each other, and that there is strong reason for belief that a large number of the deaths that occur in the first month after birth depend on tetanus infection at the umbilicus. An attempt is being made to reduce this mortality. Another cause of infant mortality is exposure to cold due to non-use of sufficient clothing because of poverty or ignorance.

FOREIGN.

Concealment of Tattooing.—A female criminal has recently been on trial at Paris, who has been able to escape punishment several times by failure to identify on the part of her accusers. She claimed that she could not be the person sought, as her accusers could not have failed to note some extensive tattooing marks on her arm, as she showed the court, and yet no one had seen them, as her accusers confessed. A chemist was finally found who produced a cosmetic which caused the immediate disappearance of all evidences of tattooing—its effect lasting several hours. She had used some preparation of the kind to disguise her identity during her crimes, and had escaped justice for years by this means.

Medicolegal Evidence of Strangulation.—A young man was on trial at Mans, France, charged with strangling a young woman. The medicolegal experts, Drs. Blaise and Persy, testified to the strangling from the signs of congestion found in the lungs of the cadaver, the cyanosis of the lips, the swollen tongue projecting beyond the teeth and the foam that had collected in and around the mouth. They thought that the victim must have been strangled for one-half to four minutes to produce these signs. Brouardel did not see the corpse, but his testimony controverted that of his colleagues. He affirmed that the findings reported by the other experts indicated that the death of the young woman had been due to inhibition. She had succumbed to a violent excitation, affecting the region of the neck, which had caused the sudden stoppage of the heart. If she had not been taken by the neck she would not have been dead, but there was no evidence of strangling. None of the signs mentioned are proof of strangulation. The experts debated the matter an hour in the court, Persy concluding with the remark that "Brouardel's declarations leave us nothing to do but to make a bonfire of our text-books on medicine, for they contain scarcely anything but errors." The prisoner was acquitted of the charge of deliberate murder, and condemned merely to three years in prison.

LONDON LETTER.

Exemption from Vaccination.

The extent to which persons make use of the vaccination act of 1898, which exempts from vaccination children whose parents have a "conscientious objection" to the proceeding, is revealed by figures given by the president of the local government board. The number of certificates of exemption granted amounts approximately to 387,000. The greater number—200,000—were granted between the passing of the act and the end of the year 1898. This was due to the fact that certificates could be obtained during the four months after passing the act in respect of all children born prior to that date, while in respect of children born after that date the certificate must be obtained within four months of the birth of the child. How many of the exempted have been attacked by smallpox is not known, but several cases have been reported. No doubt in the future these exemptions will furnish an excellent soil for an epidemic of the disease.

The Sporozoa in Men and Animals.

Professor Minchin of the University of London has delivered a series of lectures on the sporozoa group of microbes which have become very important in connection with the etiology of malaria and other tropical diseases and cancer. He pointed out that the sporozoa were a group of protozoa widely distributed in nature and universally parasitic. There is perhaps no species of worm, mollusc, crustacean, insect or vertebrate which is not liable to become the host of some sporozoon. Their characteristics are in direct relation with their habit of life as internal parasites. Their nutriment is always fluid, the blood plasma or juices of their host, which are absorbed osmotically. Hence, none of the organs for ingesting or digesting solid food, so frequent in other protozoa, are ever found. The sporozoa are very fertile, an abundant progeny of several hundreds of motile spores (swarm spores) being liberated from the body of the parent within the tissues of the host. Thus the common earthworm harbors a sporozoon (monocystis agilis) which infests the vesiculi seminales and lives within the sperm mother cells. Around the margin of these cells the spermatozoa develop while the parasite grows within the cell until it attains full size and becomes covered with a layer of spermatozoa. The growing parasite is pear-shaped and consists of a single nucleated protoplasmic body which soon issues from its spurious covering and leads a free life (sporont stage). Sporonts when fully grown conjugate in pairs or gametes. Each pair secretes a cyst wall within which the protoplasm and nuclei undergo segmentation into numerous small oval masses of nucleated protoplasm (zygotes). Each zygote divides by repeated fission into eight smaller organisms within a single covering (sporozoites). These undergo no further development in the earthworm. But when the latter is devoured by birds the sporozoites are set free and pass out with the feces to be swallowed by the worm and so repeat the cycle.

The Pasteur Institute of India.

The annual report of the Pasteur Institute of India contains some interesting facts. In the year August, 1902, to August, 1903, 584 patients underwent antirabic treatment. Of these 269 were Europeans and 315 were natives. There were six failures, a percentage of 1.02. In addition there were six cases in which treatment failed because patients went too late to the institute. These cases are not counted as failures because the nerve centers were invaded before it was possible to produce immunity. In such a case hydrophobia sets in with certainty within fourteen days. Lieutenant-Colonel Semple, director of the institute, points out that the only trusworthy test of a rabid brain or cord is inoculating an animal, and that only a small portion of the brain, cord or medulla need be sent to the laboratory in sterile neutral glycerin. An antirabic serum is prepared to improve the treatment in badly bitten and late cases, by diminishing the time required to produce immunity. The serum is derived from young, healthy ponies highly immunized with the virus of rabies. The results were most satisfactory, and as the serum destroys the virus in a mixture it is thought that it may be valuable as a first dressing for the bite and for inoculation into the tissues around. These points are being investigated. Injected hypodermically it has no effect in preventing rabies inoculated subdurally. In badly bitten and late cases the object is to confer as soon as possible a high degree of immunity. With this serum a passive immunity is conferred while the patient is developing the more durable active immunity which can be attained only by inoculation with the virus. Cultures of anthrax bacilli were obtained so attenuated as not to convey the disease to the animals on which they were used but strong enough to confer active immunity. Anti-venomous serum is now being sent out from the institute for use throughout India. The horses used in preparing it are immunized with cobra venom, with viper venom, and with mixed venoms. Children and persons of feeble physique require large doses of antivenene. In a case of cobra bite when the patient is seen early and before symptoms have occurred the antivenene may be injected hypodermically in the loins. A patient may be saved at a much later stage by giving the antivenene intravenously. The report is a very valuable one, and maintains the reputation of the Indian Medical Service for scientific work.

The London Milk Supply.

The dangers arising from contamination of the London milk supply have been previously referred to in The Journal. The question of the control of the milk supply has given rise to much discussion recently at the Society of Medical Officers of Health. The society resolved to urge the local government board to carry out its statutory powers by which it may make general and special orders dealing with the registration of dairymen, inspection of cattle, sanitation of dairies, cleanliness of milk vessels, etc.; to bring in legislation to give effect to the recommendations contained in the report of the departmental committee on food preservatives and coloring matter, which was issued in 1901; and to ensure the carrying out of the dairies orders of 1885, 1886 and 1889, especially in rural districts. It seems that most of the dirt in milk finds its way into it before it reaches the town. Consequently Mr. Wynter Blyth, health officer for the metropolitan borough of Marylebone, recommends an organized system of inspecting milk at railway stations and in the yards of large contractors.

Plague in South Africa.

In Johannesburg since the first report of plague, on March 20 down to April 5, there have been 128 cases, of which 15 were in white people. The deaths amount to 70, of which 7 occurred in whites. The great majority of the patients are Asiatics. The report of the health officer for the year ending June, 1903, gives support to the suspicion expressed by Sir Walter Foster (a well-known physician) in the house of commons, that seeds of plague must have lurked in the town to account for the sudden and startling announcemenet of 30 deaths in 38 cases. The report describes 8 cases of suspected plague. Three occurred in April of last year, and the symptoms were so striking that the medical attendants regarded them as plague, but bacteriologic examination was negative. In January, 1903, there was a notable mortality among rats, but the bodies were examined with negative results. In April rats died in large numbers in the market buildings, and the bodies of 38 were sent to the government bacteriologist, but were too decomposed for examination. Alarmist rumors were circulated at the time, but were contradicted on the ground that plague bacilli were not found. The recent outbreak gives strong grounds for believing that rats have been dying of plague for many months, and that Johannesburg has been long contaminated with the disease. In Cape Colony during the two weeks ending March 12, 8 fresh cases and 2 deaths are reported from Port Elizabeth. Capetown appears to be the only place in South Africa which has eradicated plague after it has been established. This success is attributed to the extermination of rats by the use of Danysz's virus.

Great Increase of Plague in India.

In the weeks ending March 5, 12 and 19 the deaths from plague in India numbered 28,919, 33,517, and 40,527 respectively—the latter two mortalities far exceeding any previously recorded. Since the disease appeared in 1896 the highest weekly mortality occurred for three weeks in April, 1903, when it amounted to 30,000.

DUBLIN LETTER.

The Health of Dublin.

The annual report of the Dublin Sanitary Association draws attention once again to the scandalous condition of the health of Dublin. Judged on theoretical grounds there would seem to be no reason why Dublin should not be an exceptionally healthy city. Lying between open country and open sea, easily drained and on dry soil, supplied with water of unquestionable purity, with its population largely suburban, it yet has the highest death rate of any city in Europe. At the present time, although we are unusually free from epidemic disease, our death rate is the same as that of Calcutta where bubonic plague is present. Curiously enough the rate of zymotic disease is, as a rule, low in Dublin, the chief mortality being due to tuberculosis and diseases of the respiratory system. One would expect that the health authorities would have made some move to cope with the fearful tuberculosis plague which decimates our population, but not a finger has been lifted by them. Anything that has been done has been accomplished by the energy of such voluntary bodies as the National Association for the Prevention of Tuberculosis, while the Dublin health committee sits dumb. No attempt is made to prohibit spitting, either in the streets or in public conveyances; no attempt is made to render tuberculosis a notifiable disease; none to provide public sanatoria or isolation hospitals for sufferers. Four years ago the lord lieutenant appointed a committee to inquire into the causes of the high death rate in Dublin. In its report various suggestions, obvious enough, were made to the public health committee. Not one of them has yet been carried out. Two years ago, smallpox was rampant in London, Liverpool, and Glasgow—all in daily communication with Dublin. No provision was made to meet its probable spread to this city, so that when one or two cases were imported they had to be treated in an ordinary fever hospital. Infection was there allowed to spread, and Dublin was barely saved from an epidemic. Calling for close attention also is the high rate of infant mortality. More than one-third of the deaths occurring annually are of children under five years of age, and of these the majority are uncertified. It seems hopeless to expect our authorities to stir themselves to any activity to promote the public health, and as long as the interests of publicans and slum owners are considered of paramount importance, Dublin will retain its pre-eminence as the most unhealthy city in the world where plague is not raging. About half the corporation of the city, from whom the public health committee is elected, are publicans. Our medical officer of health, I should mention, is a knight, a companion of the bath, and probably the best-known diner-out and story-teller in Dublin. He was two years ago awarded the Harben gold medal on account of his distinguished services to hygiene.

A Medical Provost for Trinity College.

The long delay in appointing a provost for Trinity College has been ended by the nomination of Dr. Anthony Traill. Although he never practiced medicine he holds medical degrees, and he is the first medical man who has ever held the post. Indeed, with the single exception of the famous Hely Hutchinson, who held office toward the close of the eighteenth century, he is the first layman to do so. Dr. Traill's appointment is taken as signifying the abandonment by the government of Lord Dunraven's university scheme, as he was its most violent opponent.

Correspondence.

Johnson's Early Sign of Pregnancy Observed in the Fundus.

Boulder, Colo., April 14, 1904.

To the Editor:—Dr. H. L. E. Johnson mentions in The Journal, Feb. 20, 1904, the alternate changing of color, from violet to pink, shown in the vaginal cervix of the pregnant uterus as early as four weeks. An opportunity to observe this sign in the fundus uteri was given us a few weeks since. March 15, 1904, a woman, three and one-half months pregnant, presented herself at the University Hospital (Medical Department, University of Colorado), for relief from intestinal obstruction. Her condition was so grave that it was thought advisable to make an exploratory incision. The incision revealed a right parovarian cyst with twisted pedicle. During the removal of the cyst, the fundus uteri was in plain view and the delicate successions from a pale to a bright pink were truly beautiful. The alternations occurred exactly every sixty seconds. They were not a gradual shading from a pale to a bright pink or vice versa. The change in color began in the center of the fundus, passing outward in the form of a circle toward the periphery in a marked, clear-cut circular wave. The patient made an uneventful recovery without interruption of the pregnancy.

L. M. Giffin, M.D., and O. M. Gilbert, M.D.

College Credit for Medical Study.

New York City, April 13, 1904.

To the Editor:—In the first editorial in The Journal, April 9, on page 956, the Medical College of Cornell University is mentioned as giving a six-year course, at the end of which the A.B. and M.D. degrees can both be obtained. Kindly note that this is an error. The university, during the first four years of the existence of its medical department, did have such a course, but since 1902 the time required for obtaining the combined degrees has been extended to seven years. In spite of this extension of time more students every year have considered it advantageous to take their A.B. degree as a precedent to entering the medical course. I trust that you will correct the statement you have made, as The Journal has such wide circulation.

John Rogers, Jr.,
Secretary Cornell University Medical College.

Lactagol—To Promote Lactation.

New York City, April 12, 1904.

To the Editor:—In The Journal, March 12, in the department of "Current Medical Literature," there is an abstract from an article in the *Berliner klinische Wochenschrift* on lactagol [page 744, abstract 80]. In reference thereto we call your attention to the fact that you make it appear that lactagol is a powdered product of cottonseed. We are just in receipt of a communication from Messrs. Pearson & Co. of Hamburg, the manufacturers of the preparation, in which we are requested to inform you that the preparation is an extract of cottonseed and not the cottonseed itself.

Lehn & Fink.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

LETTER HEADS.

It is not always possible to tell the character of a man by his letter head, but sometimes it is possible to make a pretty good guess. A physician from a western state writes his letters on paper, in the upper right hand corner of which appears this card:

> THE HABIT CURES, SURGERY, and special work. The Ultra Violet Rays. Betz Hot Air Apparatus, local and full body. Robertson Comminuter for nose, ear, throat and lung work. Alkaloidal and Specific Medicines—large supply. Careful diagnosis, up-to-date drugs and methods. United States Pension Examining Surgeon.

Marriages.

Lewis J. Daniels, M.D., to Miss Anna Jung, both of Milwaukee, April 20.

Foster F. Potter, M.D., to Mrs. Grace E. Ranios, both of New York City, April 8.

Fletcher K. White, M.D., Sewickley, Pa., to Miss Anna B. Graff, at Duluth, Minn., April 7.

Thomas P. Davis, M.D., Nashville, Tenn., to Miss Myrtle Bass of Linwood, Tenn., April 5.

Roy V. Baketel, M.D., Manchester, N. H., to Miss Helen Tenney of Methuen, Mass., April 6.

George S. Bubb, M.D., McKee's Rocks, Pa., to Miss Sara N. Brown, on Neville Island, Pa., April 6.

Charles W. Cole, M.D., Norton, Kan., to Miss Maud Alice Daggett of Phillipsburg, Kan., March 30.

Austin Fox Riggs, M.D., to Miss Alice, daughter of Dr. Charles McBurney of New York City, April 4.

R. Quarles McClure, M.D., Forrest, Texas, to Miss Fae McClelland of Mount Pleasant, Texas, April 7.

M. Martha MacVean, M.D., Nebraska City, to William Edmonds, M.D., of Erie, Pa., at Chicago, April 4.

Thomas Littleton Savin, M.D., Baltimore, to Jessie Ella Sweet, M.D., of Pine Bluff, Ark., at Baltimore, April 6.

Charles W. Keel, M.D., Newport News, Va., to Miss Virginia Lesueur, at New Canton Court House, Va., April 6.

Joseph D. Condit, M.D., New York City, to Miss Katherine Aylett Guernsey of Port Hope, Ont., in New York City, April 5.

Deaths.

Sarah Fowler Stockwell, M.D. University of Michigan, Ann Arbor, 1876, a member of the American Medical Association, the Indiana State Medical Association, and of the St. Joseph County Medical Society, one of the pioneer woman physicians of the west, died at her rooms in South Bend, Ind., April 2, from cancer, after an illness of several months, aged 62.

John I. Skelly, M.D. Detroit Medical College, 1869, a member of the American Medical Association, and a surgeon of repute, a member of the hospital corps in the Civil War, died at his home in Pekin, Ill., April 9, from apoplexy, aged 57. Tazewell County Medical Society, at a meeting held April 12, adopted resolutions of regret.

J. Howard Rabe, M.D. Jefferson Medical College, Philadelphia, 1894, of Clyde, Ohio, died at a hospital in Philadelphia, April 2, after an operation for the removal [illegible] 7. At a meeting of the Sandusky County [illegible] a committee was appointed to draft resolutions of eulogy and regret.

Josiah C. Donham, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1867, in 1889 representative to the state legislature and for the last four years superintendent of schools in Hebron, Maine, died at his home in that place, April 7, aged 66.

John P. Manker, M.D. Chattanooga (Tenn.) Medical College, 1894, instructor in physical diagnosis in that institution, died at his home in Chattanooga, April 9, from paralysis, after an invalidism of seven years, the result of a fall from a horse.

Cyrus Kindrick, M.D. Jefferson Medical College, Philadelphia, 1848, one of the organizers of the Maine Medical Association, died at his home in Litchfield Corner, Maine, where he had practiced for 52 years, April 4, aged 78.

Thomas S. Clark, M.D. Medical College of Ohio, Cincinnati, 1873, sometime president of Lewis County (Ky.) Board of Health, died at his home in Vanceburg, April 4, from paralysis, after a short illness, aged 55.

James H. Crabbs, M.D. Eclectic College of Medicine, Cincinnati, 1859; College of Physicians and Surgeons, Keokuk, Iowa, 1872, died at his home in Fremont, Neb., April 9, after an illness of two years, aged 77.

Clinton Joseph Schadt, M.D. University of Pennsylvania, Philadelphia, 1890, for eleven years a surgeon on transatlantic liners, died at his home near Egypt, Pa., April 5, from Bright's disease, aged 40.

Philip Bissell, M.D. College of Physicians and Surgeons, New York, 1902, a member of the house staff of the New York Hospital, died in that institution, April 10, from pneumonia, aged 27.

Weller Roos, M.D. Bellevue Hospital Medical College, New York, 1883, died at his home in Chenango Forks, N. Y., March 31, from consumption, after an illness of ten years, aged 50.

John E. Bradbury, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1884, died at his home in Rockland, Mass., from tuberculosis, after a lingering illness, April 7, aged 44.

Erastus P. Fairmans, M.D. College of Physicians and Surgeons, New York, 1854, a surgeon in the Army during the Civil War, died at his home in Hardwick, Vt., April 6, aged 74.

Francis M. Harris, M.D. Cincinnati College of Medicine and Surgery, 1863, died at his home in Vincennes, Ind., April 4, from cancer, after a long illness, aged 67.

Emanuel L. Howerter, M.D. University of Pennsylvania, Philadelphia, 1889, of Kempton, Pa., died recently at the home of his parents in Allentown, Pa.

Peter S. Duff, M.D. Homeopathic Hospital College, Cleveland, 1870, was found dead at his home in Herman Station, near Butler, Pa., April 2, aged 80.

James S. Dennison, M.D. Willamette University, Salem, Ore., 1872, formerly of Pomeroy, Wash., died at Walla Walla, Wash., April 5, from paresis, aged 54.

Cyrus R. Stuckslager, M.D., surgeon during the Civil War, died suddenly at his home in McKeesport, Pa., from heart disease, April 7, aged 75.

John M. Teal, M.D. Physio-Medical College, Cincinnati, 1862, died suddenly at his home in Findlay, Ohio, from heart disease, April 8, aged 73.

Romain C. Barless, M.D. Jefferson Medical College, Philadelphia, died at his home in Rose, N. Y., April 3, after a short illness, aged 70.

Sylvanus E. Parker, M.D. University of Buffalo, 1877, died suddenly at his home in Naples, N. Y., April 4, from heart disease, aged 53.

Thomas J. Jordan, M.D. Missouri Medical College, St. Louis, died at his home in Hickory Hill, Mo., April 7, from apoplexy, aged 42.

Augustus A. Guy, M.D. Albany (N. Y.) Medical College, 1893, died at his home in Harpursville, N. Y., March 30, aged 44.

J. H. Moran, M.D., died suddenly at his home in Pueblo, Colo., April 2, from heart disease, aged 55.

William J. Maercklein, M.D., died recently at his home in Milwaukee.

Miscellany.

MALPRACTICE DEFENSE AND ITS SUCCESS.

The Result of the Medical Defense Work of the New York State Medical Association.

"The proof of the pudding is in the eating," and "An ounce of practice is worth a cartload of theory," are proverbs that apply to the question of medical defense. Until the last year or two it was a theory whether medical defense was a function that can be performed by the profession itself in its organized capacity. Now practical experience has demonstrated its practicability. The Chicago Medical Society has given its members the protection with such satisfactory results that the council of the Illinois State Medical Association has decided to recommend that it be taken up by the state body. We hope shortly to give a report of the work done in this line by the Chicago Medical Society. At this time we desire to call attention to the fact that among the other work of practical value to its members, taken up by the New York State Medical Association, is that of medical defense, and the remarkable success of this work, as shown by the report covering the fiscal year now closed, is worth more than a passing notice. The following abstract of this report shows how absolutely successful this defense has been, and adds more proof of the contention that most of such cases were purely blackmailing and strike cases.

1. Philip Kronenberger brought an action against Dr. McC. of New York, by an attorney named Robert Kuhnert. The physician brought a counter claim as part of the defense for services. The result has been that up to the present the complainant has not made a move. This is clearly an attempt to defeat the physician's bill, which is sure to fail.

2. An action brought by Dr. J. of New York City against one Harvey to recover on a bill. This action was originally in the hands of a collector, and when the physician threatened suit the person attended threatened to sue for malpractice. Counsel for the association was brought into the case, advised an immediate suit for the bill, and the defendant then set up a counter-claim of malpractice; both were tried and the physician collected his bill.

3. An action brought against Dr. von D. of the Bronx, in which counsel of the association acted as counsel only, the attorney of record having already put in an answer before the application for defense was made. The result was absolutely satisfactory in this case.

4. William Naeher of Buffalo brought an action against Dr. G. of Buffalo; the summons was served in April, 1903; it was recently discovered that the plaintiff had left the state, and counsel went to Buffalo and compelled the discontinuance of the action. This was clearly an action brought for strike, but, of course, failed.

5. Maurice S. Casey of New York City brought an action against Dr. S.; another physician was joined in this action also, the plaintiff charging that both were jointly liable for the death of an infant. This action was brought by Lawyer Oppenheim. This action has never been put on the calendar—doubtless a strike. If the case is ever brought to trial it is hopeless for the plaintiff.

6. Wood, as administrator, brought an action against Dr. W., a well-known surgeon of New York City, in Queens County. The case was tried before Judge Marean and a jury in Long Island City, who returned a verdict for the defendant.

7. An action was threatened against Dr. M. of New York City, a well-known surgeon, in which malpractice was charged. The surgeon promptly turned the case over to the counsel, with instructions to the plaintiff to send all future communications to him. There the case is ended.

8. Another threatened action was that charging Dr. De W. of New York City with malpractice. He has turned over the papers, signed the necessary agreement with the result that nothing has yet been done in the direction of a suit.

9. There are two other actions now pending at Rome and Utica, respectively against Dr. C. of Sylvan Beach and Dr. D. of Boonville, N. Y., one of which will be tried, the other doubtless will be abandoned.

10. This case is that of the Sommervilles, husband and wife, against Dr. Van L., brought by Messrs. Flynn & Kohn, attorneys of Nassau Street, in which it is charged that the damages arose by reason of the defendant going on his vacation. These cases have never been put on the calendar, and were doubtless brought because the physician sued had just purchased a house, and the plaintiff, relying on the rumored timidity of medical men, hoped for a settlement.

None of these actions could have been defended individually for less than $250, many of them for not less than $1,000, showing what a great saving and benefit generally this malpractice defense has become.

Abortion of Acute Tonsillitis with Quinin.—Nine years of experience has convinced a Hungarian confrère, Dr. Szentgyörgyi of Budapest, of the great value of quinin for aborting acute tonsillitis. Its action has proved as specific as in malaria. His communication is quoted in detail in the *Semaine Médicale*, xxiv, 5, 1904. The quinin, he states, must be given for the purpose in two doses of 7.5 grains each, with a half-hour interval, and taken about 7 p. m. Four or five hours afterward there follows an actual crisis as in pneumonia, with sweating, and by the next evening all the local symptoms have disappeared. He adds that this specific action is absent in case of scarlet fever or diphtheria, and the quinin may thus aid in the differentiation of these affections.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Medical Examiners of Iowa, May 2-3 at Sioux City. Secretary, J. F. Kennedy, M.D., Des Moines.

Illinois State Board of Health, Chicago, April 25-27, and East St. Louis, May 4-6. Secretary, J. A. Egan, Springfield.

Nevada State Board of Medical Examiners, Carson City, May 2. Secretary, S. L. Lee, M.D., Carson City.

Louisiana State Board of Medical Examiners, Tulane Medical College, New Orleans, May 6-7. Secretary, F. A. Larue, M.D., New Orleans.

Mississippi State Board of Health, Jackson, May 10-11. Secretary, J. F. Hunter, M.D., Jackson.

State Board of Medical Examiners of South Carolina, State House, Columbia, May 17. Secretary, S. C. Baker, Sumter.

University of the State of New York, State Medical, Homeopathic and Eclectic Boards, New York, Albany, Buffalo and Syracuse, May 17-20.

Board of Medical Examiners of the State of North Carolina, Raleigh, May 18. Secretary, G. W. Pressly, Charlotte.

Maine Report.—Dr. A. K. P. Meserve, secretary of the Maine Board of Registration of Medicine, reports that at the examination held at Portland, March 23, 1904, 100 questions were asked on 10 subjects, and a percentage of 75 was required. Of the 10 who were examined, 9 passed and 1 withdrew. The latter was a graduate of Syracuse University Medical Department in 1884. The successful candidates were as follows:,

College.	Year Grad.	Per Cent.
Laval University, Montreal, (1897) 85.3, (1892) 87.08, (1901) 83, (1902) 85.8.		
Harvard Medical School	(1903)	90.7
Jefferson Medical College, Philadelphia	(1903)	89.8
Medical School of Maine	(1894)	78.5
Royal Coll. of P. and S., Edinburgh	(1903)	86.3
University of Vermont	(1902)	90.2

Nebraska Report.—Dr. Geo. H. Brush, Beatrice, secretary of the Nebraska State Board of Health, reports that at the written examination held at Lincoln, Feb. 10 and 11, 1904, 80 questions were asked on 8 subjects, and a percentage of 75 was required. The two who were examined passed.

College.	Year Grad.	Per Cent.
Western Medical College, London, Ont	(1901)	80.25
University of London, England	(1898)	94.75

Illinois Report.—Dr. J. A. Egan, Springfield, secretary of the State Board of Health of Illinois, reports that at the written examination held at Chicago, Jan. 14 to 16, 1904, 110 questions were asked on 11 subjects, and a percentage of 75 was required. Of the 43 who were examined 34 passed and 9 failed. They were graduates of the following schools, with grades as follows:

College.	Year Grad.	Per Cent.
PASSED.		
Rush Medical College, Chicago. (1880) 84, (1902) 88, 86,	(1903) 89, 86, 84, 86, 83, 92, 85, 91, 88, 90, 87, 82, 89, 84, 85.	
American Med. Miss. Coll., Chicago	(1901)	85
Hahnemann Medical College, Chicago...(1900) 82,	(1903)	85
Harvard Medical School, Boston	(1880)	79
Harvey Medical College, Chicago	(1903)	79
Chicago Homeopathic Medical College	(1903)	85
Illinois Medical College, Chicago	(1904)	85
Louisville Medical College	(1903)	77
Marion Sims-Beaumont Medical College, St. Louis	(1902)	82
Missouri Medical College, St. Louis	(1896)	82
Northwestern University Medical School, Chicago	(1903)	92
National Medical University, Chicago	(1903)	81
Royal University, Naples, Italy	(1898)	83
University of Iowa, Iowa City	(1885)	79
University of Sciences, Hungary	(1901)	85
University of Tennessee, Nashville	(1891)	83
FAILED.		
Illinois Medical College, Chicago........(1900) 69,	(1904)	73, 69
Coll. of Med. and Surg. (Physiomedical), Chicago	(1903)	71
National Med. University, Chicago....(1903) 58,	(1904)	70
College of Physicians and Surgeons, St. Louis	(1895)	71
Rush Medical College, Chicago	(1886)	67
Royal University, Naples, Italy	(1902)	66

Association News.

AMERICAN MEDICAL ASSOCIATION.

Fifty-fifth Annual Session, at Atlantic City.

To the Members of the American Medical Association, and to Constituent State Associations:

The next annual session of the American Medical Association will be held at Atlantic City, New Jersey, on Tuesday, Wednesday, Thursday and Friday, June 7, 8, 9 and 10, 1904. The first general meeting, which constitutes the opening exercises of the scientific functions of the Association, will be held at 10 a. m., Tuesday, June 7.

The Registration Department will be open from 8 a. m. to 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, June 6, 7, 8 and 9, and from 9 to 11 a. m. on Friday, June 10.

NEW MEMBERS.

Those who join the Association at its annual session must present certificates of membership in good standing in their state association or in one of its affiliated branches.

THE HOUSE OF DELEGATES.

The House of Delegates of the American Medical Association will convene at the High School Building, Atlantic City, New Jersey, at 10 a. m., Monday, June 6, 1904. Each constituent state and territorial association is entitled to one representative for each 500 of its resident regular members, or fraction thereof. "State associations or societies in counting members for a basis of delegate representation in this House shall count only members in good standing, who pay regular dues to the state association, either directly or indirectly through county societies."

"Members of the House of Delegates shall be elected for a term of two years, and those state and territorial associations entitled to more than one representative are requested so to arrange such elections that one-half of their delegates, as near as may be, shall be elected each year." (Chap. III, Sec. 4, By-Laws.)

GEORGE H. SIMMONS,
Secretary of the American Medical Association.

Clinics in Connection with Atlantic City Session.

The Colleges and Hospitals in Philadelphia have arranged a schedule of clinics and demonstrations which will be complimentary to the members of the American Medical Association. These will be held the week before and the week following the fifty-fifth annual session, June 7 to 10, at Atlantic City. A full schedule will be published soon. Dr. DeForest Willard is chairman of the committee in charge.

Atlantic City Hotels.

For a list of the hotels at Atlantic City and their prices, see THE JOURNAL, April 2, page 912.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending April 16, 1904:

Miller, Reuben B., asst.-surgeon, leave granted in S. O. 66, War Department, to take effect on being relieved from Army Medical School, instead of June 1, 1904.

Moseley, Edward B., deputy surgeon general, leave of absence extended three months and granted permission to go beyond the sea.

Powell, Wm. A., asst.-surgeon, relieved from duty as surgeon on transport *Thomas*, to take effect on arrival of transport at Manila, and will then report to commanding general, Philippine Division for assignment to duty.

Mabee, James I., asst.-surgeon, reports change of status "en route to station" to absent on thirty days' leave.

White, J. Samuel, contract surgeon, granted leave of absence for one month, about April 15.

Fisher, William C., contract dental surgeon, ordered from Fort Brady, Mich., to duty at Columbus Barracks, Ohio.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending April 16, 1904:

Parker, E. G., P. A. surgeon, detached from the *Adams* and ordered to the *Wheeling*.

Odell, H. E., P. A. surgeon, detached from the *Wheeling* and ordered to the *Adams*.

DeVries, J. C., A. A. surgeon, resignation accepted, to take effect April 11, 1904.

Green, E. H., medical inspector, detached from duty as fleet surgeon of the Asiatic Fleet and ordered home and to await orders.

Drake, N. H., surgeon, detached from the *Maine* and ordered to the *Lancaster*.

Kite, I. W., surgeon, detached from the Navy Yard, Norfolk, and ordered to the *Maine*.

Woodward, J. S., asst.-surgeon, detached from the Naval Proving Grounds, Indian Head, Md., and ordered to the *Brooklyn*.

Gill, J. E., asst.-surgeon, detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the *Kearsarge*.

Lumsden, G. P., surgeon, detached from the Naval Recruiting Station, Chicago, and ordered to the Navy Yard, Norfolk, Va.

Biddle, C., surgeon, detached from the *Lancaster* and ordered to the Asiaatic Station, via *Solace*, for fleet surgeon on board the flagship.

Kennedy, J. T. [illegible] d from the Naval Academy and ordered to [illegible] duty to accompany Marine detachment to t [illegible] Exposition, St. Louis.

Wise, A. H., [illegible] from the Naval Hospital, Naval Home, Philadelphia, and ordered to the Naval and Marine Rendz., Chicago.

McCullough, F. E., P. A. surgeon, ordered to the *Wisconsin*.

Smith, C. G., asst.-surgeon, detached from the *Newport* and ordered home to await orders.

Campbell, F. E., asst.-surgeon, detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to the *Newport*.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended April 14, 1904:

Greene, J. B., P. A. surgeon, granted extension of leave of absence, on account of sickness, for sixty days from Feb. 25, 1904.

Warren, B. S., asst.-surgeon, granted extension of leave of absence for one day.

Ward, W. K., asst.-surgeon, granted extension of leave of absence for four days from April 7, 1904.

Stiles, C. W., chief of Division of Zoology, detailed to attend meeting of Medical Association of Mississippi at Jackson, Miss., April 20-22, 1904.

Gregory, G. A., A. A. surgeon, granted leave of absence for three days from April 12, 1904.

Jackson, J. M., A. A. surgeon, granted leave of absence for five days from April 20, 1904.

Rodman, J. C., A. A. surgeon, granted six days' leave of absence from April 12, 1904.

BOARD CONVENED.

Board convened at Stapleton, N. Y., April 18, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon Preston H. Ballhache, chairman; P. A. Surgeon A. C. Smith, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the period from April 9 to April 15, 1904:

SMALLPOX—UNITED STATES.

California: Los Angeles, March 26-April 2, 2 cases; San Francisco, March 28-April 3, 1 case.
Illinois: April 2-9, Chicago, 8 cases, 1 death; Danville, 4 cases.
Iowa: Des Moines, April 2-9, 1 case.
Louisiana: New Orleans, April 2-9, 2 cases, 1 case imported.
Maryland: Baltimore, April 2-9, 1 case.
Michigan: April 2-9, Detroit, 1 case; Grand Rapids, 2 cases.
Missouri: St. Louis, April 2-9, 11 cases.
New Hampshire: Manchester, April 2-9, 1 case.
New Jersey: April 2-9, Camden, 2 cases; Trenton, 2 cases.
New York: Buffalo, April 2-9, 2 cases.
Ohio: April 1-8, Cincinnati, 3 cases; Cleveland, 3 cases; Dayton, April 2-9, 4 cases, 1 death.

Pennsylvania: April 2-9, Johnstown, 1 case; Philadelphia, 20 cases, 5 deaths; Pittsburg, 5 cases, 1 death, 1 case imported.
South Carolina: Charleston, April 2-9, 4 cases.
Tennessee: Nashville, April 2-9, 2 cases.
Wisconsin: Milwaukee, April 2-9, 2 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Feb. 6-13, 3 cases.
Argentina: Buenos Ayres, Feb. 1-29, 58 deaths.
Austria: Prague, March 12-19, 1 case.
Brazil: Rio de Janeiro, March 6-13, 45 cases, 30 deaths.
Canada: Winnepeg, March 26-April 2, 4 cases.
China: Hongkong, Feb. 21-28, 2 deaths; Shanghai, Feb. 27-March 5, 6 deaths.
Colombia: Barranquilla, March 21-27, 1 death.
France: Paris, March 19-26, 16 cases, 1 death.
Great Britain: Dundee, March 12-19, 4 cases; March 19-26, Edinburgh, 5 cases, 2 deaths; Leith, 10 cases, 1 death; London, 54 cases (erroneously reported April 9 as 84); Manchester, 12 cases; Newcastle-on-Tyne, 3 cases; Nottingham, 11 cases, 1 death; South Shields, 1 death; Glasgow, March 25 April 1, 18 cases, 2 deaths.
India: Karachi, March 6-13, 14 cases, 3 deaths.
Japan: Nagasaki Ken, to March 8, 27 cases.
Mexico: Vera Cruz, April 2-9, 1 case.
Russia: St. Petersburg, March 12-19, 9 cases, 5 deaths.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Feb. 13-20, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, March 6-13, 6 cases, 1 death.
Ecuador: Guayaquil, March 12-19, 4 deaths.
Mexico: Vera Cruz, April 2-9, 1 case.

CHOLERA—FOREIGN.

India: Madras, March 5-11, 2 deaths.
Turkey in Asia: Basra, March 26-31, 5 cases, 7 deaths.

PLAGUE.

Africa: Cape Colony, March 5-12, 6 cases, 3 deaths; Transvaal, Johannesburg, March 20, 8 deaths.
Australia: Sydney, March 10, 1 case.
Brazil: Rio de Janeiro, March 6-13, 4 cases, 1 death.
Egypt: Port Said, March 18, 1 case.
Formosa: Feb. 29-March 6, 96 cases, 49 deaths.
Mauritius: March 3-10, 3 cases.

Medical Organization.

Indiana.

Clark County Medical Society.—Physicians of the county met at Jeffersonville, April 7, and organized a medical society on the standard plan, and elected Dr. David C. Peyton, Jeffersonville, president; Dr. Edward L. Elrod, Henryville, vice-president; Dr. Claude C. Crum, Jeffersonville, secretary and treasurer; Drs. W. Marshall Varble, Harry C. Sharp and William H. Sheets, Jeffersonville, censors, and Dr. Cadwallader Jones, Jeffersonville, delegate to the State Medical Association.

Louisiana.

Webster Parish Medical Society.—Physicians of the parish met at Minden, recently, and with the assistance of Dr. Norwood K. Vahce, Shreveport, councilor for the Fourth District, organized a medical society on the standard plan with the following officers: Dr. Risdon W. Smith, Dubberly, president; Dr. R. C. Thompkins, vice-president; Dr. Shelly F. Martin, Minden, secretary, and Dr. Thomas J. Vance, Minden, treasurer.

Maryland.

Howard County Medical Association.—This association was reorganized on the standard plan at Ellicott City, April 5. The following officers were elected: Dr. William R. Eareckson, *Elkridge, president;* Dr. Thomas W. Linthicum, Savage, vice-president; Dr. William B. Gambrill, Alberton, secretary-treasurer, and Drs. John W. Lacy, Lisbon, Samuel J. Fort, Ellicott City, and Bernard J. Byrne, Ellicott City, censors. All the counties of Maryland now have societies.

New Jersey.

Essex County Medical Society.—By vote of the Essex District Medical Society at its meeting in Newark, April 5, the society was reorganized on the standard plan with the following officers: President, Dr. Richard C. Newton, Montclair; vice-president, Dr. William S. Disbrow, Newark; secretary, Dr. Archibald Mercer, Newark, and treasurer, Dr. Charles D. Bennett, Newark.

Ohio.

Huron County Medical Society.—Dr. Thomas C. Martin, councilor for the Fifth District, met with the physicians of the county at Norwalk, and organized a medical society on the standard plan. Dr. Samuel A. Orwig, Bellevue, was elected temporary chairman, and Dr. Hugh L. Judge, Norwalk, secretary. The election of permanent officers was deferred until the next meeting, April 21.

Texas.

Brazos County Medical Association.—On April 7, Dr. Sam R. Burroughs, Buffalo, councilor for the Eleventh (Brazos Valley) District, met the physicians of the county at Bryan and organized a medical association on the standard plan, with the following officers: Dr. James M. Nicks, Stone City, president; Dr. George W. Emory, Bryan, vice-president; Dr. Paul M. Raysor, Bryan, secretary and treasurer; Drs. A. L. Mondrick, Bryan, Henry L. Fountain, Bryan, and R. H. Wilson, Kurten, censors; Dr. A. L. Mondrick, Bryan, delegate to the State Medical Association, and Dr. Paul M. Raysor, Bryan, alternate.

Washington.

Chelan County Medical Association.—This association met for organization on the standard plan at Leavenworth, April 1. Dr. W. M. McCoy, Leavenworth, was elected president, and Dr. H. A. Saunders, secretary. The other officers will be elected at a meeting to be held in Wenatchee, May 5.

Wisconsin.

Organization.—Up to April 1, 57 out of the 71 counties in the state had been organized on the standard plan.

Society Proceedings.

COMING MEETINGS.

American Medical Association, Atlantic City, N. J., June 7-10.
Texas State Medical Association, Austin, April 26.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 26-28.
Arizona Medical Association, Tucson, April 27-28.
Arkansas Medical Society, Texarkana, May 3-5.
Louisiana State Medical Society, Lafayette, May 3-5.
Nebraska State Medical Society, Omaha, May 3-5.
Kansas Medical Society, Topeka, May 5-7.
Utah State Medical Society, Ogden, May 10-11.
Association of American Physicians, Washington, D. C., May 10-11.
Oklahoma Territory Medical Society, Oklahoma City, May 11.
Illinois State Medical Society, Bloomington, May 17-19.
State Medical Association of Missouri, St. Louis, May 17-19.
Montana State Medical Association, Butte, May 18.
Indiana State Medical Association, Indianapolis, May 19-20.
Iowa State Medical Society, Des Moines, May 18-20.
New Hampshire Medical Society, Concord, May 19-20.
North Dakota State Medical Society, Fargo, May 21-22.
American Gynecological Society, Boston, Mass., May 24.
Connecticut Medical Society, New Haven, May 25-26.
Michigan State Medical Society, Grand Rapids, May 25-27.
American Medico-Psychological Association, St. Louis, May 30-June 3.
Medical Society of the State of North Carolina, Raleigh, June 1.
South Dakota State Medical Association, Redfield, June 1-2.
Maine Medical Association, Portland, June 1-3.
Minnesota State Medical Society, Minneapolis, June 2-3.
American Dermatological Association, Niagara Falls, June 2-4.
American Therapeutic Society, New York City, June 2-4.
Rhode Island Medical Society, Providence, June 3.
Indian Territory Medical Association, Holdenville, June 3-5.
American Academy of Medicine, Atlantic City, June 4-6.
Medical Society of New Jersey, Atlantic City, June 4-7.
American Gastro-Enterological Association, Atlantic City, June 6.
Massachusetts Medical Society, Boston, June 7-8.
Association of American Medical Colleges, Atlantic City, June 7.
American Orthopedic Association, Atlantic City, June 7-9.
American Urological Association, Atlantic City, June 10-11.
Medical Society of Delaware, Lewes, June 14.
Wisconsin State Medical Society, Milwaukee, June 22.

TENNESSEE STATE MEDICAL ASSOCIATION.

Seventy-first Annual Session, held at Chattanooga, April 12 to 14, 1904.

Under the presidency of Dr. I. A. McSwain of Paris.

Addresses of welcome were delivered by Hon. A. W. Chambliss, mayor of Chattanooga, and by Dr. J. R. Rathmell.

The response to these addresses was made by Dr. C. A. Abernathy of Pulaski.

Dr. J. N. McCormack of Bowling Green, Ky., delivered an admirable address on organization. His remarks created a favorable impression. He furnished the secretaries of the county medical societies some valuable pointers relative to this work.

The House of Delegates transacted the business brought before it expeditiously. It met promptly one hour in advance of the scientific sessions, thus enabling the members of the house to hear all the papers that were read and to take part in the discussions. The members agreed that this method of transacting business so as not to interfere with the scientific work was an admirable one.

The address of the president was on the subject, "The Two Sciences—Medicine and Humanity." This will be published in The Journal.

Officers.

The following officers were elected for the ensuing year: President, Dr. Paul F. Eve, Nashville; vice-presidents, Drs.

E. H. Jones, Murphreesboro; G. O. Bicknell, Madisonville, and C. E. Tyree, Trenton; secretary, Dr. Deering J. Roberts, Nashville; treasurer, Dr. W. C. Bilbro, Murphreesboro.

The association decided to meet in Nashville, April 11 to 13, 1905.

(To be continued.)

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

Meeting of the Section on Clinical Medicine and Surgery, held March 18, 1904.

DISCUSSION ON PNEUMONIA.

Some Recent City Statistics.

DR. J. HALL PLEASANTS said 105,971 persons died from the disease in the United States in 1900. The high death rate this winter is a wave on the pneumonia tide which set in several decades ago, and has continued steadily to rise. If anything like the present rate of increase is maintained in the death rate and if the consumption rate continues to fall or even remains stationary, the next census will show pneumonia established as the principal cause of death in the United States. The remarkable comparative rate of increase is shown by a comparison of the census figures of 1890 and 1900 of consumption and pneumonia. Pneumonia deaths, 1890, 76,496; 1900, 105,971; consumption deaths, 1890, 102,188; 1900, 109,750. In other words, in 1890 somewhat over 9 per cent. of all deaths were due to pneumonia, in 1900 over 10.5 per cent.; in the same period the mortality from consumption decreased from 12.23 per cent. to 10.99 per cent. Comparing city with country, the census of 1900 shows for pneumonia mortality per 100,000 inhabitants of cities, 233.1; for rural districts, 135.9; for consumption, cities, 204.8; for rural districts, 134.1. The mortality from pneumonia among negroes is 349 per 100,000, and among whites 184.8. Whites of foreign birth were shown to be much more susceptible to pneumonia than those of American birth. These statistics apply to both lobar and lobular pneumonia.

The statistics for Baltimore were next given for the past 50 years. A chart was exhibited showing that from about 35 deaths per 100,000 in 1850 from pneumonia, the rate had increased by 1875 to 149, and steadily thereafter until in 1903 it reached 206. Particularly high waves of mortality were seen in 1890 and 1900 due to epidemics of influenza; the mortality in 1900 reached about 253. The figures for the present season, so far, show 624 deaths, against 584 for the same period of last year, not such an alarming increase as was to be expected. During the present season, so far, 494 deaths have been reported from consumption. The percentage, therefore, of pneumonia to all deaths in this period is 16.5, and of consumption 13.1. The pneumonia mortality reached its climax with the week ending March 5, when 75 deaths were reported in a total of 302. The figures for the past fortnight are less alarming, and it is improbable that the death rate will reach the high-water mark of 1900. Various explanations of the recent high pneumonia death rate in Baltimore were discussed. Some thought it due to the fire, but the increase did not reach its maximum for three weeks after that, and, moreover, a similar increase is widespread over the country. Climatic conditions are probably the important factors. For only one year could the death rate from pneumonia among negroes be given. Of the 1,101 deaths from pneumonia in 1903, there were 726 among the whites and 375 among the negroes. The negro population of the city constitutes from one-sixth to one-seventh of the whole, and their general death rate is more than twice that of the whites.

Bacteriology, Serum Therapy and Immunity.

DR. WILLIAM H. WELCH said that the present stage of progress did not hold out any hope of a protective antitoxin owing to the low vitality of the pneumococcus in artificial inoculations. It must be confessed that little had been learned from the discovery of the pneumococcus that had aided the diagnosis or treatment, and there was absolutely nothing that could be called a specific in the disease. The germ is in a large percentage a normal occupant of the healthy human throat. Alcoholism and other debilitating conditions lower the power of resistance of the individual and increase the susceptibility to the disease. The idea is growing in Chicago, New York, and other places that the disease is propagated by contagion, as by the consumption sputa and the prevalence of the disease in a number of cases in one house or neighborhood speak for this idea. While this mode of spread must be recognized as a possibility, Dr. Welch thought that the majority of cases are due to the development or relatively increased virulence of the organism in the body.

Experience at the Johns Hopkins Hospital.

DR. WILLIAM OSLER said that after 26 years of hospital practice he found pneumonia everywhere the same disease as it was at the beginning of his career. Variations are seen, but the mortality in all large series of cases is about 25 or 26 per cent. Dr. Osler spoke of the training given his students in the hospital, and said that he believed that if one trained a student properly in pneumonia and typhoid fever, as the Bible suggests, all other things would be added unto him.

Treatment.

DR. I. E. ATKINSON concluded the discussion. There is no specific. He emphasized the need of sleep to the patient, advising the repeated injection of morphin, if necessary. The ice-bag to the affected side may suffice in milder cases. The warm bath gradually cooled is highly efficacious in children. He advised blood-letting, not in the beginning, but later to relieve extreme dilation of the heart. Alcohol and large doses of strychnin are called for for weak heart. Too great care to keep the patient from catching cold is harmful, and too much covering is undesirable. Oxygen is useful, but should be begun early. Saline injections are also useful by diuretic action, carrying off the toxin. The above treatment was for the severe cases. Overmedication is dangerous. One can generally foresee severity in a case and direct his measures accordingly. All expectorants are harmful.

MEDICAL SOCIETY OF THE CITY AND COUNTY OF DENVER.

Regular Meeting, held April 5, 1904.

Dr. W. J. Rothwell in the Chair.

Symposium on Medical Laws.

HON. I. B. MELVILLE, assistant attorney general of Colorado, discussed the relations of osteopathy to the medical laws of the state. He pointed out that the constitutional provisions protecting the freedom of the individual in the enjoyment of his religious beliefs did not extend to any practice that would injure his neighbors, or militate against the general welfare. He cited the mormon church and the practice of polygamy. In the same way, while a man may practice whatever system of medicine he may prefer, and while people of mature minds may choose any system, such practice must be carried on under restrictions that will prevent harm to others or to the community at large. Protection must also be given by the state to the immature and helpless. It is with this end in view that the general police powers of the state permit laws requiring a certain standard of qualification for those engaging in the practice of medicine. The osteopaths, while proclaiming in public and in the lobbies of the legislature that the medical laws were especially aimed at them, when proceeded against for the illegal practice of medicine, had set up the claim that the practice of medicine consisted entirely of the giving of drugs; and that, therefore, medical laws did not apply to them at all, because they gave no drugs. This contention had received some support in the lower courts, but it was opposed by the bulk of decisions in other states, and by two decisions that had been rendered by the Colorado Supreme Court with reference to the medical practice act of Colorado.

In the case of Mrs. Harding, an electropath, who undertook to practice after failing to obtain a license of the State Board of Medical Examiners, the lower court ruled that the medical practice act prohibited her from engaging in her peculiar system of practice without such license; and the supreme court upheld this decision. In the other case a certain Brown assumed the title of M.D., was convicted of illegal practice, and the decision of the lower court affirmed.

Mr. Melville pointed out how the recent verdict against the State Board of Medical Examiners and in favor of an osteopath had been reached. Dr. Van Meter had consulted several leading lawyers who had agreed that "Dr." Bass was violating the medical law. He then took the matter to the district attorney, who concurred in this view, had information drawn, and commenced proceedings. These were quashed by the judge before whom the matter was brought. Then Dr. Bass sued Dr. Van Meter and the State Board of Examiners for damages for malicious prosecution. Although the law and universal practice everywhere protect a citizen from any such suit on account of actions brought through the public prosecutor, Judge Millins ruled that the board of examiners were liable for damages on this account. It had been hoped that through this case a ruling of the Supreme Court might be obtained, defining the relation of the medical practice laws of Colorado to the practice of osteopathy. But the trial in question was so full of errors that the verdict was likely to be set aside without this important point being touched on.

Hon. H. E. Kelley, counselor for the Colorado Medical Legislative League, spoke of some legal experience bearing on the need of organization of the medical profession. The Colorado Bar Association, although it did not include by any means all the lawyers in the state, nor have the support of any law, was a body of such standing, force and activity, that it practically compelled honesty and decency on the part of all who would practice law in Colorado. In regard to the conduct of a legal case, there would be as many opinions as there were lawyers. Some yielding was always necessary. To get any efficient medical law, individual ideas and preferences must be sacrificed. All must agree on the common ground of requiring a searching scientific education of all who would practice *medicine. Those best fitted should be chosen to consider the* situation, and the most practical law to meet it; and then the loyal support of the whole profession should be given to this measure, and to aid those working for it.

He pointed out that when the Sanford bill was before the governor last year, prominent and generally respected physicians had advised him to veto it. There was lack of unity on the part of the medical profession. The first need was to instruct and convert some of the physicians. Then the subject must be explained to the public. When this was done there would be no difficulty in getting support for such measures. In spite of all that is said, the profession is held by the general public responsible for the public health. The medical profession had plenty of influence, if it would unite and use it.

Dr. W. W. Grant, president of the Colorado Legislative League, wished to point out that there were certain things the profession of Colorado were not responsible for. They were not responsible for Judge Mullins, or for the two governors that had vetoed two excellent medical laws. He referred to the Colorado plan of organization and the unanimous approval of it by the National Council of Medical Legislation. He read an editorial from The Journal of the American Medical Association, supporting that plan. The medical profession must fight unqualified practitioners. No self-respecting medical man could vote for one who would degrade our profession to the standpoint of the quacks.

Dr. Edward Jackson said that the effort to define the practice of medicine was an effort to prevent the taking of money under false pretense. Through the work of an educated body of practitioners the words "doctor of medicine" and "medical practice" had come to have a certain significance. To prevent the application of these words to those who did not possess these qualifications was an effort to check misrepresentation and falsehood. The first steps of the quack were to assume the title of "Dr." and to give out that he was engaged in the same kind of medical practice. No one, physician or layman, could afford to assist this form of misrepresentation and falsehood.

Dr. S. D. Van Meter called the attention the committee appointed by the National Legislative Council to draft a form of medical practice act which should serve as a model in all the different states, and which, with only such modifications as were necessary to meet the different state constitutions, should be recommended for universal adoption. He showed a certificate of death by tuberculosis signed by an osteopath, that had been presented at the office of the Denver health commissioner. He wished to point out that the fight was not against the osteopaths especially, but against all those who, professing some new school or cult of medicine, sought through it to evade the laws regulating the practice of medicine. There were sixteen such cults or "pathies" now in existence in this country, and others were liable to spring up at any time. The fight was not against osteopaths, but against any "paths."

The Journal presents below the constitution and by-laws of the league that is referred to above:

CONSTITUTION AND BY-LAWS OF THE COLORADO MEDICAL LEGISLATIVE LEAGUE.

Article I.

The name and title of the organization shall be the Colorado Medical Legislative League.

Article II.

The purpose of this league shall be to form a non-sectarian body through which the united medical profession of the state of Colorado may succeed in improving and in enforcing the medical statutes.

Article III.

Section 1.—This league shall consist of active members, honorary members and guests.

Sec. 2.—The requirements for membership in this league shall be limited only to an avowal of a desire to assist in the promulgation of the purposes of the organization and the payment of the annual dues.

Sec. 3.—Honorary membership may be conferred by a vote of two-thirds of the members present at any regular meeting.

Article IV.

Section 1.—The league shall hold an annual meeting in Denver, which shall be open to all registered and honorary members and guests.

Sec. 2.—The time for holding each annual session shall be fixed by the executive council.

Article V.

Section 1.—The officers of this league shall be a president, two vice-presidents, a secretary-treasurer and a counselor.

Sec. 2.—The officers shall be elected for a term of two years.

Sec. 3.—The five officers of the league shall be known as the executive council, which shall meet from time to time at the call of the secretary, for the transaction of business.

Sec. 4.—The chairmen of the respective committees on legislation from the different state societies shall, as far as practicable, be members of the council, and at all times each school of medicine must be represented.

Article VI.

The funds for meeting the expenses of this league shall be derived from the annual dues of its members and by voluntary contribution.

Article VII.

Section 1.—All elections shall be by secret ballot and the majority of the votes cast shall be necessary to elect.

Sec. 2.—In balloting for any officer, if on the first ballot no one receives a majority of the votes cast, the name receiving the smallest number of votes shall be dropped, and the balloting shall proceed in this manner until an election is had.

Article VIII.

Section 1.—The president shall preside at all meetings of the league.

Sec. 2.—The secretary-treasurer shall give bond for the trust reposed in him, whenever the executive council shall deem it requisite. He shall demand and receive the funds due the society, together with voluntary donations. He shall pay out of the treasury only on a written order from the president. He shall submit his accounts to such examination as the league may order, and he shall annually render an account of the expenditures and of the receipts and funds in his hands.

Sec. 3.—The secretary-treasurer shall perform the ordinary duties of secretary and treasurer for the league and its executive council.

Article IX.

The annual dues shall be $2.00, payable in advance.

Article X.

The chairman of the legislative committee of the National Auxiliary Congressional and Legislative Committee for Colorado, of the Colorado State Medical Society, the State Homeopathic Association and the Colorado State Eclectic Society, shall be, if not among the members of the executive council, ex-officio members of said council.

NEW YORK ACADEMY OF MEDICINE.

Meeting of the Section on Orthopedics, held March 3, 1904.

The Vice President, Dr. Virgil P. Gibney, in the chair.

The paper of the evening was read by John Ridlon, M.D., Chicago, on "The Ultimate Results of the Bloodless Replacements of Congenitally Dislocated Hips." This is published in full in The Journal, April 16 and 23.

DISCUSSION.

Dr. H. Augustus Wilson, Philadelphia, said that Dr. Lorenz had operated on nine cases in the Jefferson Medical College Hospital in Philadelphia, the results of which are as follows: There are three perfect anatomic and functional results. These patients are under two years of age; one a single dislocation, the other double. Three cases have good functional results. By that it is meant that they are so far improved over their former condition as to make the trivial limp apparent only to an expert. This gives 66.6 per cent. successes.

Six out of the nine have good functional results. One was not reduced—a child aged four, who had been previously subjected to various forms of tenotomy, stretching in bed, extension, had worn a brace a considerable length of time. In this case there was failure to produce a reduction. Lorenz attempted reduction and failed, after almost exhausting his strength. It was put up in typical position, and in six months radiograph showed the hip to be not reduced. The ultimate result was great improvement of function.

A double case, in six months, after the original cast was removed, showed apparent typical replacement. The conditions which made it slip were undoubtedly due to the misunderstanding of the physician in charge of the necessity for the weight-bearing feature emphasized by Dr. Lorenz. This child was kept at rest, sitting or lying in bed. At no time was it taught any method of extending the legs to get the hamstrings in full extension. It did not step on its foot for six months. The muscles of both legs were atrophied from disuse, the ham-string tendons were contracted so that the knees could not be straightened, and that made the joint slip from a very shallow acetabulum.

Dr. Lorenz, in June last, saw the case and found it necessary to etherize the child and stretch the hamstrings again. Notwithstanding the second manipulation on the hamstring tendons, both hips slipped.

Dr. Wilson had been surprised at the low valuation that Dr. Lorenz placed on the radiographs in cases of congenital dislocation. Dr. Wilson thought they were useful as a matter of record rather than as a test of conditions.

The radiograph of several cases showed a deep acetabulum, completely deceiving those interested as to the real conditions present, which were found to be filled with cartilage and fibrous tissue.

Casually alluding to the results in the thirty-two cases under his observation in Philadelphia, Dr. Wilson said there had been no paralysis of any sort, nor disturbance of the circulation. In one case there was temporary edema of the vulva, necessitating catheterization for forty-eight hours; after that, function returned.

There is a question as to whether we are justified in considering the classification of perfect anatomic results. Perfect anatomic results do not always give the best functional results, and function is the object always desired. It is clearly impossible to make a new hip that will be anatomically perfect in cases that have been born with abnormal hips, and the highest ideal should be to obtain functional recovery and a functional result is not always obtained in a so-called anatomic replacement.

A boy eleven years of age, by radiograph and palpation, showed a full, anatomically perfect replacement, but he had rigid, stiff hips which possibly might become limbered up after a while, but were far from a functional recovery.

We are making too fine a distinction in classes of cures. If we can form a standard of functional recovery, we will be attaining higher percentage of successful results, and be doing justice more fully to the man who has taught us.

Dr. E. H. Bradford, Boston, said that the congenital dislocations of the hip during twenty years at the Children's Hospital, Boston, had been carefully examined and the results were most encouraging in that it appeared that the percentage of absolute anatomic cures had been steadily increasing. By cures was not meant functional cures, or transpositions, but results by which the head was replaced in the acetabulum with perfect restoration of gait, shown by measurements, by palpation, by observation and by skiagraph record, and it is probable that in the near future these will be the results that the surgeon will expect to attain.

Relapses occur after congenital dislocations of the hip have been reduced, in a large number of cases. Dr. Bradford entirely agreed with Dr. Ridlon that in operable cases, the manipulative method as demonstrated by Dr. Lorenz was the method of choice. This may not, however, be considered a permanent solution of the question. Improvements in technic were to be expected in this as in other branches of surgery.

Relapse, as we understand after-treatment more thoroughly, may be expected to become less frequent. At present manipulative methods are to be tried in all operable cases. Where this fails, owing to a folding of the capsule in front of the reduced head, incision is advisable. In cases with osseous change, operations on the bone are considered.

It would seem that anatomically there is no greater difficulty in the cure of congenital dislocation of the hip than in the cure of congenital club foot, and in the next decade we may consider congenital dislocation of the hip one of the readily curable deformities.

Dr. R. Whitman, New York City, said that from his own experience he could not accept Dr. Ridlon's statistics as representative. In his opinion in properly selected cases (the younger the patient the better the prospect of cure) 40 per cent. of the cases should be perfectly cured by this method. He did not, however, limit himself to the Lorenz operation, but having failed by that method he would recommend arthrotomy. By this means one might assure himself that the head of the femur was actually within the acetabulum, or if the femur were so twisted as to make permanent apposition impossible, one might restore the normal relation by means of osteotomy. Finally the old Hoffa-Lorenz operation might serve as a last resort to assure stability, which was hardly possible without bony support. It was true that the best result by this method could not compare with the perfect cures attained by bloodless reduction. The average result, however, was better than after transposition. He was inclined to think then that when bloodless surgery had found its limit one should supplement it by other surgery, and that by a more comprehensive treatment the results would be greatly improved.

Dr. Whitman said that there were different varieties of transposition which had not been recognized, apparently, in the statistics presented. One was caused by hyperextension, in which the head of the femur was forced too far forward so that it could be felt and seen directly beneath the femoral artery. In cases of this character the limb remained, when the plaster bandage was removed, in an attitude of abduction and extension; motion could be restored only by persistent manipulation, and in some cases an anesthetic might be necessary to lessen the distortion. Yet in this class of cases the final result was likely to be good, and even perfect, because of the permanency of the reduction. If, on the other hand, the head of the femur were just outside the femoral artery, the result was usually unsatisfactory in that the shortening was progressive until the head came to a resting place beside the anterior superior spine. In only one class of cases could such transpositions be regarded as a good result. If, for example, one had transformed a bilateral posterior into a bilateral anterior displacement, the contour of the body was improved and the symmetrical disability was markedly decreased, but if in such a case one side were actually cured and the other transposed, the surgeon might be accused of injuring the patient because the swaying gait had been changed to a noticeable limp. In such a case one should always perform the open operation with the aim of assuring stability, even at the expense of a part of the range of normal motion.

Dr. A. Jacobi, New York City, asked the earliest age at which a patient should be operated on when found to have congenital dislocation of the hip. A case might be discovered when a baby was but a few months old; is any operation in order at this time?

Dr. Newton M. Shaffer, New York City, thought Dr. Ridlon's statistics formed an intelligent and comprehensive basis for judging of the Lorenz operation and its results. His own cases could not be well judged yet, but in all of them—and all were apparently successfully reduced—the tendency to the condition known as the "anterior transposition" was marked. He thought that Dr. Ridlon's statement that this was due, in a large measure, to the conditions produced by the tearing of all the resisting tissues—especially the muscles and nerves, was correct. In the after-treatment of this condition we should study the "adaptive muscular conditions," as he termed it, more closely. Normal muscles shorten and lengthen as opportunity is given—as, for instance, in the acquired talipes equinus associated with the shortened leg in hip disease. In infantile paralysis the shortening of the unparalyzed muscles is always marked. In lateral curvature the same thing is observed. Muscles lacerated as in this operation, for instance, the adductor group, by the force necessary to reduce a congenitally dislocated hip, may be so far injured that it may be years before they can *regain their normal contractility, if* they ever do. Add to this a nerve injury and the condition becomes more complicated. Studying the results which have come under his observation, he said in the future he should give these muscles a much longer time to recuperate before discarding the mechanical protection. *In other* words, after the plaster-of-paris splint is removed, a simple steel support should be applied, as, for instance, in extensive infantile paralysis, embracing the pelvis with a conventional pelvic band controlling the entire limb to and involving the foot, with anteroposterior motion only at the hip, knee and ankle, with or without perineal pads, as indicated. This would place the femur and the hip under the control of the surgeon and prevent any "anterior reposition" and the "weight-bearing" principle could be scientifically applied, while the patient walks about—with the head of the femur in the acetabulum. Massage, etc., could be used to restore the lost muscular power.

He had applied this treatment to two of the patients now under observation at the State Hospital, who are doing well. He wished he had applied it to two others, who have done badly since they left the hospital, with apparently perfect reposition.

Dr. V. P. Gibney, New York City, said that the cases operated on at the Hospital for Ruptured and Crippled are hardly ready for presentation of final results, but he believed the results would compare very favorably with those shown by Dr. Ridlon.

Dr. Ridlon said that the earliest case of congenital dislocation of the hip he had had anything to do with was one of seventeen months. There can be no question that the earlier one operates the easier it is to make replacement and the less the injury. On the other hand, the earlier the operation the more difficult the retention, because the delicate baby's skin does not bear covering as does that of an older child. A baby wets the plaster splint.

One case operated on by him, which he reported on as having relapsed because the splint was wetted and bent (the child flexed and the head went out backward) was operated on by Lorenz. The result was anterior and supracotyloid displacement. It is an annoyance to have to change a plaster splint, reeking with urine, almost every week for eight months. Earlier than eighteen months, one does not recognize the dislocation; generally not until the child has walked.

In one case a child had club foot and congenital kyphosis, coming for treatment when six weeks old; it was not known that she had a dislocated hip until she was nearly three years old. From two to four years is the period of choice—when the child is old enough to be cleanly.

As to Dr. Whitman's remarks that the greatest thing to be desired in the treatment of congenital hips would appear to be stability, the speaker would not agree. He had the pleasure of examining cases operated on and cured by Dr. Whitman in 1900. They were certainly replaced and certainly stable, also certainly stiff, by the cutting operation. Dr. Ridlon did not consider a stiff hip in a good position as good for a patient to use or as desirable as a hip with which he can walk, with just a little limp, which can be bent to a sitting position. He thought it best to get a functional result even if not a perfect anatomic replacement.

Dr. Whitman also spoke of different transpositions. Those cases in which the head has lain back of the artery, Dr. Ridlon had called extreme anterior transposition in contradistinction to those lying to the outer side of the artery and on a level with the acetabulum as shown by the *x*-ray; where the head could be felt but not seen, while those back of the artery can be seen as well as felt by him.

One point was not brought out in the paper—the ultimate result of dislocation of the head, anterior and directly behind the artery. Some results are counted as good if the head is in this position. Dr. Ridlon did not think we knew what the ultimate result would be when the head is back of the artery, but feared that it may arrest development of that limb with growth. It might not happen, but is to be feared. Dr. Whitman says those lying back of the artery do not go up; this is very likely true.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Iodin in Enlarged Glands.

Wyatt Wingrave, in British Med. Jour., states that, being specially interested in the supplemental treatment of enlarged glands and adenoids with iodin, he has obtained, after experimenting for many years, an iodin combination that can be given for a considerable period without causing symptoms of iodism while exercising its specific action. The form now used successfully is *iodin in* a loose chemical combination with tannic acid as follows:

℞.	Iodi (pure)	gr. xxxviiss	2	50
	Acidi tannici	ʒi	4	
	Alcoholis (90 per cent.)	ʒx	40	
	Syrupi simplicis	℥iiss	75	

M. Dissolve the iodin in alcohol and add the tannic acid and one ounce of the syrup; heat to just below the boiling point until the solution affords no evidence of free iodin, with starch reaction (about 20 minutes). Cool and add the remainder of the syrup. Sig.: One-half to one teaspoonful before meals, according to age.

Each teaspoonful contains two grains of iodin.

The foregoing is useful in chronic lymphadenitis, associated with or independent of adenoids, enlarged faucial tonsils and large cervical glands.

In atrophic rhinitis gratifying results have been obtained, especially when combined with arsenic. It is also of value in the treatment of bronchocele.

Diarrhea of Typhoid Fever.

The following combination is recommended by the *Dublin Jour. of Med. Science* to check the diarrhea of typhoid fever:

℞.	Bismuthi carb.	gr. x		65
	Sodii bicarb.	gr. v		30
	Cretæ prep. arom.	gr. xx	1	30
	Tinct. opii	gtt. v		30
	Spts. chloroformi	gtt. x		65
	Sodii salicylatis Pulv. tragacanthæ, āā	gr. x		65
	Aquæ q. s. ad	℥i	30	

M. Sig.: To be taken at one dose and repeated as indicated, to check the diarrhea.

Cough in Tuberculosis.

Dr. D. B. King, in an abstract in the *N. Y. and Phil. Med. Jour.*, recommends, in the treatment of the cough in tuberculosis which occurs on rising in the morning, that the patient be instructed to sip slowly a cup of hot milk, to which 15 to 30 grains of sodium chlorid has been added.

For the cough occurring at night he advises the administration of the pilula ipecac. et scillæ (B. P.) grains 5 (.30).

For excessive coughing through the day the following is recommended:

℞.	Pot. citratis	gr. xv	1	
	Liq. ammon. acetatis	ʒii	8	
	Tinct. scillæ	m. xii		75
	Vini ipecacuanhæ	m. x		65
	Aquæ anisati q. s. ad	℥i	30	

M. Sig.: At one dose for the cough.

Or a better combination is as follows:

℞.	Apomorph. hydrochlor.	gr. 1/24		0025
	Morph. hydrochlor.	gr. 1/8		008
	Acidi hydrochlor. dil.	m. ii		12
	Oxymel	m. xx	1	30
	Glycerini	m. x		65
	Aquæ q. s. ad	ʒi	4	

M. Sig.: At one dose.

Or the following containing both apomorphin and heroin:

℞.	Apomorphin. hydrochlor.	gr. 1/24		0025
	Heroin	gr. 1/16		004
	Terebene	m. x		65
	Mucil. acaciæ			
	Syr. tolutani, āā	ʒi	4	
	Aq. camphoræ q. s. ad	℥ss	15	

M. Sig.: To be taken at one dose.

Apocodein is also recommended by the author as of service in checking the cough:

℞.	Apocodeinæ	gr. 1/10		006
	Terebene	m. x		65
	Mucil. acaciæ	ʒi	4	
	Aquæ camphoræ	℥ss	15	

M. Sig.: At one dose.

In cough which persists while the patient is at rest relief is often given by the patient taking moderate exercise.

As an injection in tuberculosis the following is recommended by *Clinica Moderna*:

℞.	Iodi (pure)	gr. viiss		50
	Pot. iodidi	gr. lxxv	5	
	Crys. guaiacol	ʒiiss	10	
	Glycerini (pure)	ʒx	40	

M. To be used hypodermically, beginning with a few drops of the solution.

Diseases of the Eye.

The following combinations are recommended by L. Webster Fox, in *Med. Bull.*, in the treatment of diseases of the eye:

EDEMA OF THE LIDS.

℞.	Liq. plumbi subacet. dil.	ʒii	8	
	Tinct. opii			
	Tinct. belladonnæ, āā	ʒiss	6	
	Tinct. arnicæ	℥i	30	
	Aquæ camphoræ			
	Aq. destil., āā, q. s. ad	℥ iv	120	

M. Sig.: To be applied locally.

[It seems from the ingredients included that great care should be employed in using the foregoing combination.]

CONJUNCTIVITIS.

℞.	Acidi borici			
	Sodii biboratis, āā	ʒss	2	
	Aq. menth. pip.	ʒiii	12	
	Ext. hamamel. dest.	ʒiv	15	
	Aq. camphoræ			
	Aq. destil., āā	℥ii	60	

M. Sig.: Bathe the eyes freely.

OPHTHALMIA NEONATORUM.

℞.	Hydrastin hydrochlor.	gr. iv-vi		25-.35
	Acidi borici	gr. xx	1	30
	Tinct. opii deod.	ʒii	8	
	Aquæ destil.	℥iv	120	

M. Sig.: As an eye lotion.

ULCERS OF THE CORNEA FOLLOWING PURULENT CONJUNCTIVITIS.

℞.	Escrin. sulph.	gr. ¼		015
	Hydrarg. oxid. flav.	gr. ⅛-i		008-.06
	Liq. petrolati	ʒi	4	

M. Sig.: A small amount to be placed in the eye once or twice daily, followed by light massage of the lid.

Acute Rhinitis.

The following combinations are recommended by *Merck's Archives* in relieving the catarrhal condition in acute rhinitis:

℞.	Menthol	gr. ii		12
	Pulv. benzoini	ʒi	4	
	Bismuthi subnit.	ʒiss	6	
	Acidi borici	ʒi	4	

M. Sig.: A small amount to be insufflated into the nose two or three times daily; or:

℞.	Cocainæ hydrochlor.	gr. iss		09
	Iodol	gr. iii		20
	Acidi borici	ʒiss	6	
	Bismuthi subnit.	ʒi	4	
	Acidi tannici	gr. v		30
	Menthol	gr. iii		20
	Pulv. amyli	ʒiiss	10	

M. Sig.: To be insufflated; or:

℞.	Bismuthi salicylatis	ʒiiss	10	
	Pulv. camphoræ	gr. xl	2	65
	Menthol	gr. ii		12

M. Ft. pulvis. Sig.: To be insufflated into the nares three or four times daily.

Veronal in Insanity.

Veronal has been used successfully as a sedative to the nervous system by Wuerth of Hofheim in a great many cases of insanity, according to *Ther. Rev.* After treating 84 restless and troublesome insane women he has noted its relative action to other drugs. He found it to be of great value in the treatment of acute dementia, paralytic dementia, melancholia, senile dementia, idiocy, periodic insanity, epilepsy, hysterical mental disturbance, also in cases of ordinary insomnia.

As a sedative he gave from 3 to 7½ grains (.20-.50). However, double this sized dose may be given if necessary. He administers it dissolved in hot milk, hot tea, or in powder form. It produces sleep in from one-half to two hours. It is equal to double the dose of trional, and does not have that accumulative narcotic action. No ill effects have been noted by the author on the heart, kidneys or digestion.

According to the *Internat. Med. Annual*, 1904, Poly finds this preparation to be a valuable hypnotic given in capsule form in doses ranging from 4 to 12 grains (.25-.75). It is of no service in insomnia due to pain, unless combined with morphin. In some cases drowsiness, headache and dizziness were noted the following day. This preparation is specially recommended for the sleeplessness of morphinists.

[Veronal is a new hypnotic. It is the diethylmalonylurea.]

Medicolegal.

Pregnancy in Rape Case and Improbability of Conception.—The Supreme Court of Iowa says, in the case of State vs. Carpenter, a prosecution for rape, that the pregnancy of the prosecutrix has not heretofore been considered ground for a continuance. Her condition might, of course, appeal to a jury, and tend to enlist their sympathies; but the presence in the courtroom of a child born as the result, or as the claimed result, of a rape, would be quite as potent in this respect. Consequently, there was no error in overruling the motion for a continuance in this case. Indeed, the condition of the woman might well have been good ground for proceeding with the trial at that particular time. The dangers incident to childbirth may well be taken into account when such applications as this are made. A point was sought to be made as to the improbability of the witness conceiving at the time she claimed she was ravished. This was based on the theory that her last menstrual period had so far passed that conception was improbable, and on the further thought that conception at such a time was the more improbable on the state's theory of ravishment. But the court declares that it can not say, as a matter of law, that conception could not occur under such circumstances. This whole matter was for the jury.

Good Health—Aggravation of Existing Infirmity.—The Supreme Court of Georgia holds, in Atlantic & Birmingham

Railroad Co. vs. Douglas, a personal injury case brought by the latter party, that "good health" is a relative term, and does not mean absolute freedom from physical infirmity, but only such a condition of body and mind as that one may discharge the ordinary duties of life without serious strain on the vital powers. In life insurance cases, the court says, it has been held that "good health" does not ordinarily mean freedom from infirmity, and that "good health" or "sound health" means a state of health free from disease or ailment that affects the general soundness and healthfulness of the system seriously. When the party suing in this case alleged, therefore, that she was in good health, her petition was not to be construed as alleging that she was perfectly sound and free from all infirmities; and, consequently, when, under the evidence, it appeared that she was laboring under an infirmity of which she was ignorant, but this infirmity did not interfere with the discharge by her of the ordinary duties of life, and probably would not have ever interfered with her but for the injuries resulting from the negligence of the railroad company, she was not precluded from recovering simply because it developed that the injuries to her were the result, not of the negligence of the company alone, but of that negligence and a pre-existing infirmity, which up to that time had not been the occasion of any inconvenience to her. Or, as the court restates it, *when, in a suit by a female against a railroad company* for damages for personal injuries, it is alleged that she was, prior to the injuries, "in good health," a recovery may be had notwithstanding it appears from the evidence that at the time of the injuries she was laboring under an infirmity of which she was ignorant, and which did not interfere with the discharge by her of the ordinary duties of life, and that the result of the negligence of the railroad company was, not to produce an infirmity, but simply to aggravate the existing infirmity.

Not Liable for Death from Smallpox Communicated by Nurse.—*In reversing the decision in* M., K. & T. Ry. Co. of Texas vs. Freeman, reported on page 1676 of The Journal of June 13, 1903, the Supreme Court of Texas holds that, under the statute of that state, the company was not liable for death from smallpox communicated by an unreliable nurse intrusted by one of its local surgeons with the care of a pest camp. It says that to make the negligence of the surgeon that of the employer required the aid of the rule respondeat superior, the superior or master must answer. This, however, is eliminated by the Texas statute from this class of actions, except to the extent it is made applicable to those falling within the provision giving a right of action for death "when the death of any person is caused by the negligence or carelessness of the proprietor, owner, charterer, hirer of any railroad, steamboat, stage-coach, or other vehicle for the conveyance of goods or passengers, or by the unfitness, negligence or carelessness of their servants or agents." But the servants and agents for whose misconduct liability is created are those engaged in prosecuting, in some way, the business of conveying goods or passengers; and, as in law one person acts as the servant or agent of another only when he acts in the scope of his employment, the death contemplated by the statute must be caused by the servant while prosecuting the business of conveying goods or passengers. Besides, the court thinks it evident that if such a relation as that which existed between the detention camp in question, where one of the company's servants was being taken care of, and the railroad were held to make the keeping of the camp a part of the proper business of the company as owner of the railroad conducting a carrying business, it would be found impracticable to fix a limit at which it would be possible to stop short of the broad proposition that such companies and individuals, merely because they own and operate railroads, or some of the vehicles mentioned in the statute, are responsible for all deaths caused by their employes in any business. Such a construction of the statute would take away all foundation for the discrimination which the legislature has made in the business specified in the statute and other persons and corporations, making the former responsible for deaths occurring in the prosecution of collateral business when others engaged in like collateral businesses are not held to a like accountability.

Prescribing Intoxicating Liquors for Minors.—The Court of Criminal Appeals of Texas has reversed, in Atkinson vs. State, a conviction of a physician for selling liquor to a minor without the written consent of the parent or guardian of the minor. The prescription was in the terms of the law. The minor in question was about 18 or 19 years of age, and the facts for the prosecution and the physician showed that he was sick at the time. The question as to the minority of the patient was not mentioned or discussed between him and the physician, *while the testimony of the latter indicated that, if he had thought about it at all, he would have thought the patient was about 21 years of age, but really that question did not enter his mind. He gave the prescription because the boy was sick and needed it. Furthermore, he proved good character as a physician, man, etc. The transaction occurred in local option territory.* The court treats the case from the standpoint that the physician knew or had reason to believe that the patient was under 21, with the result above stated. It says that the general rule is that, where local option has been put into operation, it constitutes the exclusive system for the regulation or manner of liquor selling in the given locality. The local option law of Texas provides that intoxicants can be sold as a medicine in case of actual sickness in a local option territory, and with no other saving clause, except the sale of wine for sacramental purposes. This is inconsistent with the law prohibiting the sale to minors except on the written consent of the parent or guardian, when liquor is sold on prescription, and, being inconsistent, it must be considered as suspending that law during the operation of the local option law. Aside from the local option law there is another phase of the case well enough to notice. From the authorities the rule is deducible that, where there are statutes like those of Texas prohibiting the sales to minors (and most of the states in the federal union have practically the same law), where the sale is for medicine it is not within the inhibition of the statute prohibiting sales to minors. This question has been frequently decided in the states of the union as well as Texas. Bowman vs. State, 38 Tex. Cr. R. 14; Ball vs. State, 50 Ind. 595; Lindley vs. Braxton, 27 Ind. 56; People vs. Board of Com. 3 Scam. 153; Hooper vs. State, 56 Ind. 156; Elrod vs. State, 72 Ind. 294; Nixon vs. State, 76 Ind. 526; 11 Amer. and Eng. Ency. of Law, 703; State vs. Wool, 86 N. C. 708.

2 *Non-operative Relief of Eyestrain for the Possible Cure of Epilepsy as Tested in 68 Cases at the Craig Colony. William P. Spratling and George M. Gould.
3 Preliminary Report of a Series of Metabolism Observations Made in Atrophic Arthritis, Hypertrophic Arthritis, Osteitis *Deformans and the Normal.* (Concluded.) Joel E. Goldthwait, Charles F. Painter and Robert B. Osgood.
4 Nervous Complications of Typhoid Fever. Herbert A. Black.
5 Cholecystectomy vs. Cholecystostomy. A Plea for the Plaintiff. Maurice Kahn.
6 *Corneal Ulceration Due to Nasal Infection. S. Lewis Ziegler.

1. **Syncytioma Malignum.**—McFarland reviews the subject of the defense of the organism against overgrowth, and applies the facts to the syncytioma. There must exist, he thinks, between the embryonal and maternal tissues a cytolitic equilibrium, through which the variations favor the embryonal tissues during pregnancy and the maternal tissues after parturition. If the ovum should fail to provide the necessary cytolytic substance, it would be unable to secure an appropriate nidus and sterility might result, or if the cells of the embryo should fail, abortion might be the outcome, or in case they did not resist the antagonistic substance of the maternal tissues until the completion of gestation, miscarriage might result. On the other hand, if the maternal tissues fail in their antagonism, we can conceive that the actively growing syncy-

tium would invade the uterine wall with abnormal rapidity or to an abnormal extent, and that during involution fragments might be retained for an indefinite period, causing local disturbance if quiescent, or disorganization and hemorrhage if active. If the ability of the maternal tissue to resist this invasion was general instead of local the formation of metastatic secondary masses in various parts of the body to which syncytial fragments were accidentally transplanted, would be the result.

2. Epilepsy and Eyestrain.—At the instance of the superintendent of the Craig colony, Dr. Gould visited it in August, 1902, and made a thorough test of the ocular conditions and the benefit of their correction in 78 patients. The number of attacks each patient had had before this study and after was recorded, and in one case in which the patient had grand mal of great severity it seems that arrest was made and a possible cure may be anticipated. He has had no attacks for a period of 11 months. Five previous arrests were possibly sustained by the use of glasses, and there was an apparent decrease of the attacks in 11 cases, though not permanent or so slignt as to make it impossible to say that it was not due to the ordinary fluctuations of the disease. In 33 cases the attacks appeared to be increased, and in 16 there was no change whatever in the symptoms. The experiments, Spratling says, seem to prove that in looking for the cause and cure of epilepsy we must not confine our attention to any single organ and its abnormalities, but must study the whole organism and its parts. He regrets that the experiments, so carefully and scientifically made by Drs. Gould and Bennett, did not yield better results, but it strengthens his opinion that epilepsy is not a "single prescription disease," so to speak, and that the correction of ocular abnormalities alone is not any more likely to cure it than surgical measures on the brain from which so much was at one time hoped. Dr. Gould publishes an addendum to the paper in which he supports his formerly expressed views and thinks that two mistakes were made in conducting the experiments: 1, that young patients and only those with less injured nervous systems should have been chosen, and 2, that resident or frequently visiting opticians and oculists should have been insured to make the retestings and readjustments when necessary. Still he considers that the apparent improvement in 19 out of 57 patients, and the one cure in 57 against one in 80 by all other methods of treatment, indicate the value of the method.

6. Corneal Ulceration from Nasal Infection.—Ziegler points out the ways in which the cornea may be affected from nasal disorder and epitomizes the treatment as follows:

1. The nose should have antiseptic irrigation and local treatment applied.
2. The lacrimonasal duct should be disinfected or dilated.
3. The eye should have a soothing lotion, a mydriatic instilled, and a cauterant applied to the ulcer, if necessary.
4. The diet should be regulated, tonic and antiphlogistic treatment given, and the hygiene generally improved.

April 9.

7 *Tuberculosis of the Spinal Cord, with Reports of Cases of Tuberculous Myelitis and of Tuberculous Pachymeningitis. Charles L. Dana and J. Ramsay Hunt.
8 *The Outlook for a More Sanitary Street-car Service in New York. George A. Soper.
9 *The Early Diagnosis of General Paresis. William A. White.
10 *Pulmonary Tuberculosis as an Infectious Disease; Its Early Diagnosis. James J. Walsh.
11 *Pathologic Changes in Tissue Under the Influence of the X-ray. William S [illegible]
12 Historical Sketch o[illegible] Cures for Consumption, with a [illegible] Treatment. (To be concluded.) J. [illegible]
13 *Normal Labor Cons[illegible] Standpoint. A. M. Pond.
14 Rubber Cushions for General Surgical, Gynecologic and Obstetric Use. Howard A. Kelly.

7. Tuberculosis of the Spinal Cord.—Tuberculous myelitis is not yet recognized as a special separate pathologic process by the neuropathologist, at least it is not described in recent works nor referred to by writers on the general pathology. Dana and Hunt report cases, however, which point strongly to such a condition. The first case was one that seems to have been a direct infection or infiltration of the cord alone. The article is illustrated.

8. Street-Car Sanitation.—Soper gives the findings of the committee on engineering and sanitation appointed by the Merchants' Association of New York, showing the sanitary deficiencies of street and elevated cars, such as sand pile spittoons, lack of cuspidors, need of better car sanitation, more frequent cleansing of the cars, better floor coverings, the unsanitary condition of the closets in the stations and the need of ventilation both on the cars and in the stations, and the better regulation of temperature. In the surface railroads there should also be better ventilation and cleansing methods. The criticisms are much the same in both cases.

9. Paresis.—White points out the underlying dementia in the psychic symptoms in incipient paresis and the various disorders from which it should be clinically diagnosticated. The principal diseases which may be mistaken for it in the early stages are tabes, acquired neurasthenia, some of the pure psychoses, alcoholism, brain tumor, cerebral syphilis and disseminated sclerosis. The differentiation from tabes is not entirely easy. The physical signs may be the same. The preservation of knee-jerks and the associated evidence of dementia, however, are characteristic when they exist. The general mental attitude of the patient in acquired neurasthenia is significant. In neurasthenia there is no dementia, disorders of speech or writing or history of seizures. The tendon reflexes are equal or abolished, the pupils equal and reaction normal, while in paresis they are more apt to be dilated, frequently unequal and very much contracted. Alcoholism may closely simulate paresis, though the disappearance of the symptoms with discontinuance of the cause is remarkable. In brain tumor the focal symptoms should be looked for, and in disseminated sclerosis the differentiation should be by tremor, nystagmus and scanning speech, though some of these cases do ultimately develop typical signs of paresis. He points out a series of differentiating signs between cerebral and cerebrospinal syphilis and paresis which he thinks may be found, and the fact that the antisyphilitic remedies produce immediate results in many cases.

10. See abstract in The Journal, xli, p. 1224.

11. Tissue Changes Under the X-Ray.—Newcomet has studied the effects of the x-ray on the tissues microscopically, though he has not been able to study a case of simple burn. In all instances there had been pre-existing disease. He reports his cases and findings and concludes that no single form of degeneration is characteristic of the x-ray. The form of degeneration observed depends entirely on the tissue exposed. The method of x-ray application, and the effect of the x-ray depends on the cell formation of the exposed parts. But why certain normal cells, such as those in the hair follicles, should be more susceptible than in other tissues is still a question.

13. Normal Labor.—Pond recapitulates the points of his article under the following heads:

1. Success in obstetrics depends wholly on ability to secure and retain surgical cleanliness.
2. The same infective ag[illegible] gical practice are the causative agents in [illegible] lications, and are only successfully comb[illegible] of stringent aseptic and antiseptic technic.
3. Refrain from making numerous vaginal examinations, and when done, execute great aseptic care.
4. Do not wait until you are called to the case to make the preparations for confinement.
5. The practice of carrying a confinement pad is dangerous. An improvised pad is easily made with a quilt rolled and pinned in horseshoe shape, with a piece of white table oilcloth laid over it. This is aseptic and inexpensive.
6. Sunshine in itself is a valuable germicide; do not exclude it.
7. Unless the vaginal discharge is known to contain pyogenic bacteria the douche is contraindicated.
8. Exert the same surgical technic in dressing the umbilicus that would be demanded in any other fresh wound.
9. Be clean and be sure that you are clean. Take no chances. By so doing you will reap a liberal temporal reward, besides having the serene satisfaction of knowing that you are serving humanity faithfully and well.

21 On Laboratory Diagnosis. (Continued.) M. P. Overholser.

15. Wiring of the Bone in Fractures.—McCurdy illustrates his experience in wiring the bone, and favors the use of iron wire, iron being a normal constituent of the system, while silver is foreign and acts as such in the tissues, abstracting sulphur and producing more or less disturbance. He recommends, first, wiring of the bone while the ends remain down in their normal position, avoiding any removal from such position if possible as destroying the normal relations of things. It also preserves the nutrition, prevents necrosis and guarantees union. He also advises anchoring of the bony fragments to an external bridgework to hold them in position during repair. He illustrates his instrument for cutting off the ends of the bones when required.

16. Skiagraphic Errors.—The usefulness of the x-ray in fractures and bony deformities is twofold. First, in cases of injury of doubtful diagnosis, especially when near the joint, to determine whether or not there is fracture, and if so, what it is. In many cases only the skiagraph will reveal the condition, especially if small fragments are chipped off. If we are sure of fracture it is far less necessary to skiagraph than it would be to have a skiagram made of a part that has been continuously diagnosed as a contusion or strain. Many times these contusions or strains prove to be fractures of small fragments of the articular surface of the bone. It may be necessary to move the tube, plate and limb in several different positions before we can detect the fracture, but a skiagram so taken must not be interpreted as representing the relative position of the fragments. It is used simply to show the fracture, and when it has done that its usefulness is over. A broader and more important field of the skiagram is to show whether there is or is not any deformity. It does not require to be taken at the time of injury, and it may be done just as well years later. It is less useful when taken early, especially if the bones are still at all movable. To show the deformity best we must resort to what we might call comparative skiagraphy. The physician or even the surgeon can not properly be asked to compare a skiagram of an injured limb with his recollection of the bone as he has studied it in his student days, and say whether there is any deformity or not. It is also untrustworthy to compare an individual skiagram with a description or composite picture, or the part of one person with the corresponding part of another. There is only one thing to compare it with, that is, the corresponding normal part of the subject. If the plate is horizontal and the part to be skiagraphed is flat on the plate in such a position that the bone will be as near the plate as possible, and if the tube is vertically over the point of fracture or deformity, we can get the best possible picture of the part. But this is not enough. We must have a skiagram of the corresponding normal part with the tube, plate, part to be skiagraphed and the relation of the part to the body as a whole in exactly the same relative position as the skiagram of the injured part. If this is done with absolute accuracy it should show any deformity that may exist. We know then that it is really deformed and not a skiagraphic error.

17. Epilepsy.—Spratling commences his paper with the following propositions:

1. Epilepsy is curable in from 5 per cent. to 10 per cent. of all cases.
2. It requires, as a rule, a long continued course of treatment—never less than two to three years—carefully mapped out and executed to the letter, not only along one, but along many lines, to effect a cure.
3. The failure to secure better results, generally, in the treatment of this disease must frequently be laid to the failure to treat the individual and his disease as a unit, and to treat them both along the very broad, comprehensive and unyielding lines they both require.
4. The drug treatment of epilepsy alone, while invaluable in many cases and of some use in every case, often fails completely to meet the most important requirements.
5. Guides to the prognosis in epilepsy are always uncertain and unsatisfactory until treatment has been in operation from six to nine months, and in some cases a year or longer.

The remaining portion of this installment of his paper is mainly given to the report of cases that have been cured at the Craig colony up to this time.

18. Trachoma.—Alger thinks that much of the so-called trachoma observed in the school children of New York is really follicular conjunctivitis according to Fuchs' classical description. The treatment, therefore, for trachoma in every case is not logical. It simply removes the diseased lymphatics, but nothing short of complete removal of the conjunctiva could remove all the lymphatics, and if contagious at all, it is just as dangerous after expression as before. The school children have none of the symptoms of acute trachoma except the soft granulations.

25 *Technic of the Removal of One-half of the Thyroid Gland. John G. Sheldon.
26 Two Cases of Splenomedullary Leukemia, Treatment and Recovery. Bertram L. Bryant and Harold H. Crane.

23. Nervous Women.—Sebring reports 5 cases from actual practice which he thinks illustrates the classes of nervous cases most frequently seen by the physician, and which give him the greatest trouble. The first was one of aggravated hysteria, which after various experiments he subdued by emetics. The second was more of a neurasthenic type with anemia and was treated by Flint's tablets and analgesics for the relief of headache, etc. The third case was an overworked woman with nervous and gastric disorders and muscle spasms, which latter were controlled by splints. He thinks this the most effectual method of treating such cases. The fourth case was diagnosed by the attending physician as one of typhoid fever, and was the result of a low febrile condition, restlessness, insomnia, etc., with abnormal temperature due to the syndrome typical of neurasthenia from long continued strain and overwork. There was some psychic disturbance in this case also. He found the fluid extract of avena sativa the most effectual remedy in this case.

24. Rectal Segment of the Ureter.—Robinson describes the anatomy of the ureter in its relation to the rectum and adjoining parts. The paper is fully illustrated.

25. Thyroidectomy.—The operation for the removal of half of the thyroid gland here recommended by Sheldon is that originally devised by A. Pearce Gould. It is described as follows:

> The gland is exposed by dividing the skin, fascia and muscles. The next step is to pass a Kocher's director or one blade of an artery forceps between the trachea and the isthmus. Usually, I remove the isthmus, and in these cases clamp the gland with a stomach clamp between the isthmus and the lobe that is to be left. When one clamp has been applied, a second one is placed close to the first and an incision made between the two clamps. I now turn the isthmus and the lobe to be removed outward and separate the under surface of the gland from the underlying structures with the finger covered with a piece of gauze. This can be easily and quickly done without injury to the gland or to the structures on which it lies. The thyroid arteries are soon exposed as they enter the under surface of the gland. If a transverse incision has been made the inferior thyroid is first exposed and clamped; if an angular incision has been used, it is easier to expose and clamp the superior thyroid before dealing with the inferior vessel. After the arteries are clamped close to the gland and cut, the removal of the remainder of the lobe is easily accomplished by blunt dissection close to the gland. The veins of the thyroid do not bleed after the arteries have been clamped; and the internal jugular vein, in the great majority of cases, gives no trouble.

The operation, he claims, is better for the avoidance of hemorrhage and of injury of the recurrent laryngeal nerve, and he believes that the thyroid can be removed with less injury to the gland by the method here described than by the ordinary technic. He advises tubular drainage for ten or twelve hours in all operations on the thyroid as a considerable amount of primary wound secretion is exuded and the contents of the gland may have been expressed into the wound during the operation.

33 *The Cystoscope—Its Diagnostic Value. A. M. Wose.
34 *Ligation of the Lachrymal Canal to Prevent Infection Following Cataract Extraction. Alex. Quackenboss.

28. **Eyestrain and Spinal Curvature.**—Three cases are reported by Kilburn which he thinks are typical. In these cases eyestrain, by inducing a faulty position, acted as an indirect factor in the production of spinal curvature. The patients were all growing girls with poor muscular development, and the rapid increase of body weight contributed to the result.

29. **Supernumerary Breasts and Nipples.**—Young reports and illustrates a case of supernumerary nipples. He thinks heredity has a certain influence in the occurrence of these deformities, and that in respect to its cause the theory of reversion to some previous type has the greatest number of adherents among writers and offers the most satisfactory explanation for the appearance of these rather interesting deformities. As regards accessory nipples, the theory of the separation of a portion of tissue is apparently the most satisfactory. It may be that some other explanation may be needed for the anomalous position of the nipple occurring on the outer side of the thigh, on the back, etc.

30. **Ring Bodies in Anemic Blood.**—In this brief communication Cabot reports that he has examined 14 cases of pernicious anemia in their active stages, 9, or 64 per cent., of which showed the presence of rings more or less similar to those previously described by him in his former article in *The Journal of Medical Research* of February, 1903. He has also found them in anemias secondary to lead poisoning as also in lymphatic leukemia. Negative results were obtained in 4 cases of pernicious anemia in the stage of remission, in 10 cases of leukemia, in 9 of severe secondary anemia and in 22 cases of various skin diseases. He gives a number of illustrations of the ring bodies, remarking that further study has only increased his ignorance in regard to their nature and origin.

32. **Neurasthenia.**—Dana considers that 50 per cent. of the cases of neurasthenia may be classed under other heads, as dementia precox, slight attacks of melancholia or manic depressive insanity, the more early development of phrenasthenia, under which he includes such states as dipsomania, hysteria, psychic states, obsessions, etc., and the exhaustion psychoses. In syphilitic cases neurasthenia is liable to be a precursor of paresis. In older persons the symptoms usually indicate a mild form of the melancholia of involution. Neurasthenia occurring after severe illnesses, toxemias, etc., sometimes shows signs of confusional psychoses, and the so-called congenital neurasthenia or chronic hypochondria is generally a dementia precox, paranoia or phrenasthenia. His contention is, first, that many cases of dementia precox are in the early stages considered neurasthenics. Also that there are abortive types of dementia precox which pass through life or many years of it, with the dementia arrested, and are classed simply as neurasthenic. The subjects break down early and are unable to continue work and have but little initiative. Simple neurasthenia occurring under twenty years of age is rarely neurasthenia. It is a dementia precox or a recurrent melancholia or the exhaustion of phrenasthenia, and it is rarely paranoia.

33. **The Cystoscope.**—The value of the cystoscope in kidney and bladder disorders is pointed out by Wose, as well as the use of the segregator instruments and catheterization of the ureters.

34. **Ligation of the Lacrymal Canal in Cataract Operations.**—Quackenboss has operated on 2 cataract cases, following the suggestion of Buller of Montreal to temporarily ligate the canaliculi to prevent wound infection in operations on the eye. He has also seen two other cases thus operated on. The canal was tied, and in each he succeeded in preventing infection. He sees no use in leaving stitches after the corneal wound has healed firmly. They caused no irritation in the case reported, and were removed at the end of two weeks. Before taking them out, pressure on the sac failed to discharge anything into the eye, but after removal a probe was easily passed and pressure on the sac caused a small amount of purulent matter to come through the puncta.

39 My Autobiography and Reminiscences. (Continued.) S. Pollak.

35. **Determination of Sex.**—The subject of sex determination is very thoroughly treated by Taussig, who concludes that the sex of the human embryo is determined far earlier than we are able at present to differentiate microscopically. The study of single-ovum twins shows that such a differentiation must have occurred previous to the formation of a gastrula, in the first days of gestation. Whether the sex is determined earlier than this in man is unsettled, but in some animals it seems clear that the sex must have been determined before impregnation. In certain plants and animals the male and female generative cell can be differentiated by its size while still attached to the mother body; here, as in parthenogenesis, it is unquestionably true that the sex is determined in the unimpregnated ovum. All observations concerning the influence on sex determination of the respective vitality of the sexual elements, comparative age of parents, etc., are based on insufficient data. The influence of nutrition on the formation of sex has been clearly demonstrated for a large number of plants and animals, and the influence of temperature can logically be explained as also a nutritive influence. The effect of any of these factors in the determination of the human sex, however, is yet unproved.

37. **An Explosive Compound.**—Fairbrother calls attention to the fact that a combination of nitric and carbolic acid is dangerously explosive. There are hardly any two agents more frequently used in dressing wounds in the surgeon's office than these. He reports an accident that occurred to him. About half a dram of each of these substances was mixed and an immediate explosion resulted.

42. **Cancer of the Pylorus.**—The operation here described by Mayo is summed up by him in the following steps:

1. Open the abdomen. 2. Double ligate and divide the gastric artery; ligate and divide the necessary amount of gastrohepatic omentum close to the liver, leaving most of its structure attached to the stomach. Double ligate and divide the superior pyloric artery and free the upper inch or more of the duodenum. 3. With the fingers as a guide underneath the pylorus, in the lesser cavity of the peritoneum, ligate the right gastro-epiploic or gastro-duodenal artery, and progressively tie and cut away the gastro-colic omentum distal to the glands and vessels up to the appropriate point on the greater curvature, and here ligate the left gastro-epiploic vessels. 4. Double clamp the duodenum, divide between with the cautery, leaving one-fourth inch projection. With a running suture of catgut through the seared stump the end of the duodenum is closed as the clamp is removed. A purse-string suture about the duodenum enables the stump to be inverted. The proximal end of the stomach

is double clamped along the Mikulicz-Hartmann line and divided with the cautery, leaving one-fourth inch projection. Suture through the seared stump with a catgut button-hole suture. This is again turned in after removal of the clamp by a continuous silk or Cushing suture. 5. Independent gastrojejunostomy. 6. Closure of the wound.

He and his brother, Dr. C. H. Mayo, have operated on 41 cases, 37 for cancer and 4 for inveterate ulcer. Of these operations 13 have been made essentially by the plan outlined, with one death. There were 6 deaths in the remaining 28 cases performed by various methods. He does not claim originality for the method; it is a composite operation. He thinks it should be the operation of choice in the average case of fairly early disease of the pyloric region.

43. **Gastric Ulcer.**—MacLaren believes that many cases of perforating ulcer of the stomach can be diagnosed in time, and that the duty of the medical man is to operate at the earliest possible moment, followed by suture of the opening with silk or linen, caulking the opening with gauze. He would sponge out a slightly soiled peritoneum, without drainage; but if there is much fluid in the peritoneal cavity a large drain should be put into the pelvis through a stab-wound over the symphysis and the patient put to bed in the Fowler position. He reports three cases in detail, all encountered in three months.

44. **Cirrhosis of the Stomach.**—Sheldon reports a case and comments on the same. He also reviews the others that have been recorded in the literature, and believes that, in spite of the claims to the contrary by most German writers, benign cirrhosis of the stomach, though a rare condition, does exist. It is difficult to diagnose, but may be suspected in patients presenting symptoms of benign stenosis of the pylorus with contracted stomach. It would be impossible in any case to exclude malignancy. The conditions that would point to it are long-standing disease, absence of hemoptysis, contraction of the stomach, absence of tumor on palpation, absence of glandular or hepatic involvement and general improvement and relief of the stomach symptoms for a period of time when rectal feeding is resorted to. It is not likely to prove fatal until the pylorus has been so nearly closed as to prevent the passage of food. The treatment is necessarily surgical.

45. **Gunshot Wounds of the Abdomen.**—The points emphasized by Harris are stated as follows:

1. In penetrating wounds of the abdomen there are absolutely no known symptoms which indicate injury to any of the viscera, except those in connection with the urinary tract, stomach and occasionally the lower bowel. 2. Except those relating to general shock, all symptoms following such wounds indicate either internal hemorrhage or peritonitis. 3. To wait for symptoms of perforation of the intestine means to wait until peritonitis has developed, therefore, 4. Every bullet or stab wound which penetrates the abdominal cavity should be operated on at the earliest possible moment in order to anticipate the advent of peritonitis. 5. No time should be wasted in attempting to demonstrate the presence or absence of intestinal perforation by such means as the rectal insufflation or gases or vapors, or the analysis of recollected intraperitoneally injected air or liquids. 6. It is essential to systematically examine the entire gastrointestinal canal in all cases, regardless of the point of entrance of the wounding body. 7. Whenever the alimentary canal has been perforated suitable drains (the author prefers the so-called cigarette drains) should be placed either through the operative incisions or counter-incisions, as may appear best suited to the individual case.

46. **Unilateral Hematuria.**—Freeman reports a case and remarks that a prominent cause of renal hematuria, which is often unilateral, is chronic interstitial nephritis, often involving the glomerules. This, with other obscure causes, must be excluded before a diagnosis of "essential hematuria" is made. Decapsulation of the kidney is indicated in these cases as affording a prospect of cure of both the hematuria and the nephritis. Nephrectomy is dangerous on account of the probability of involvement of the other kidney.

47. **Epithelioma of the Urethra.**—Hall reports a case personally observed and 3 others by Drs. Wood and Montgomery communicated to him. He also finds in the literature 21 undoubted cases of epithelioma of the bulbous urethra, which he tabulates. The rarity of the occurrence of this condition must be a mystery, he says. The urethra ought to be a common locality for cancer if Cohnheim's theory of chronic irritation be accepted. If, on the other hand, a specific micro-organism be invoked as the essential cause, it is difficult to understand its immunity, especially when we remember how easily gonococcus infection is established.

48. **Prostatectomy.**—Moore's article is a critical one on the subject of prostatectomy, pointing out its inconveniences and dangers. He thinks it is too grave an operation to be resorted to as a routine treatment, and that it is applicable only in properly selected cases. The dangers of uremia in case of kidney disease, of sepsis, which is an ever present danger, the various complications, such as injury to important blood vessels, peritoneum and nerves, hemorrhage, which, however, is not a very serious danger, the possibility of permanent damage to the urethra and of extensive injury to the bladder in case of suprapubic operation, and in the peritoneal operation, of injury to the rectum, must all be taken into consideration. Moreover, under the present technic, we do not preserve the seminal ducts, and this is certainly a grave complication. Other unfortunate sequelæ are epididymitis, incontinence or dribbling and the possibility of perineal fistula. He does not wish to be classed as a pessimist as regards this operation, but as one who recognizes difficulties with the hope of overcoming them.

50.—See abstract in THE JOURNAL of January 16, p. 191.

51. **Pyothorax.**—Beck reviews the operations for costal and thoracic resection in pyothorax, advocating early preliminary rib resection and condemning aspiration as ineffective on account of the probability of solid masses in the cavity. Baelz' treatment of aspiration with irrigation has also its drawbacks. The drain may be obstructed, the drainage tube become loose and the exclusion of air impossible. Such patients require much more careful watching than those under ordinary treatment. Simple incision through the intercostal space is undoubtedly effective in the majority of cases, but he does not consider it a good substitute for resection, the alleged difficulties of which have been overrated. He insists on the importance of individualizing in operations, and special caution at the beginning of operation. The author describes the technic in detail, illustrating the article. Two cases are reported.

52. **Pulsating Exophthalmos.**—In the case reported a man 29 years of age was struck on the left parietal region with a bottle. There was no unconsciousness or laceration of the scalp, but the second day afterward the left eye began to protrude and the eyelids to swell. The conjunctival and subconjunctival veins became enormously distended. There was headache for the first week followed by noise in the head. The left eye protruded forward at least one-half of its anteroposterior diameter; the right eye also protruded slightly forward. The operation performed was ligation of the left common carotid by two ligatures, severing the artery between the ligatures. Relief was apparently perfect for the first year; then came a relapse. Murray thinks the mistake made was in ligating the common carotid, and that the chances of recurrence would have been lessened if the internal carotid had been tied. If the patient should return for operation he would follow Woodward's example and ligate and resect the branches of the superior ophthalmic vein at the inner angle of the orbit, and, if necessary, resect a portion of the main vein. In case of failure then ligation of the opposite carotid would be indicated. The case is illustrated.

53. **Lip-Tie.**—While cases of tongue-tie are common, Griffith thinks the condition here described has not been noticed in the literature. In an Italian infant since birth there has been an attachment of the inner surface of the middle line of the entire upper lip to the gum by a fold of tissue continuous with the mucous lining of the mouth, about an eighth of an inch in thickness. When the mouth is opened the middle of the upper lip is rolled directly inward, giving rise to a peculiar expression not apparent when in repose. The treatment consisted in cutting through the protrusion half way up its extent and tearing through the remaining portion. There was a temporary hemorrhage from the operation. The result is not stated, but was probably good.

55.—This article appeared in The Journal, March 5, p. 646.

56. **Cerebrospinal Symptoms in Infectious Diseases.**—Gordon reports a case of typhoid in which there was a total motor aphasia, agraphia, word blindness, right hemiplegia, including the face, though not pronounced, and slight hyperesthesia of all forms of sensation on the same side, rigidity of both lower extremities with ankle clonus, greatly exaggerated patellar reflexes, and the Babinski sign on both sides. The patient could not stand unsupported or walk, and there was incontinence of both urine and feces. With this there were no hysterical stigmata, and the previous history made Gordon reject functional nervous disease as the cause. At the time the examination was made the patient had entered into convalescence and made an uninterrupted recovery and left the hospital in perfect health. He thinks the case is instructive, for the following reasons:

> 1. An apparently mild case of typhoid fever without any complication in other viscera may affect the whole cerebrospinal system simultaneously. 2. The nervous symptoms may be pronounced and multiple in spite of the mildness of the original disease. 3. These multiple and marked organic symptoms may be out of proportion to the general condition of the patient, as, generally speaking, we know that the more the infectious disease is pronounced in its course, the more profound is the toxemia, and the more symptoms of complications can be expected 4. The prognosis is usually favorable in cases in which disproportion is present, as these apparently alarming symptoms are only transitory in character. The case is also unusual from this point of view, that if aphasia and hemiplegia in the course of typhoid fever were rarely observed, agraphia and word-blindness, to my knowledge, were not reported.

60. **Chronic Polyarthritis in Children.**—Edsall reports a case of the type of chronic joint disease described by Still, characterized by marked enlargement of the lymph nodes, usually of the spleen, a tendency to irregularity and at times a marked fever, absence of bone deposits, and the fact of its occurrence in young children. From his study of the case he is inclined to believe that the child had a widespread tuberculosis of a low degree of virulence, which enabled him to kill off large numbers of tubercle bacilli, and, finally, to control the progress of the disease. The case presented the tuberculin reaction and microscopic examination of the lymph nodes, while at first it showed no tubercle bacilli, and inoculation experiments were negative, an emulsion from several of the lymph nodes showed a large number of acid-fast bacilli having the typical appearance of tubercle bacilli. Dr. Ravenel, who made the examination, has no doubt but that the bacilli seen were tubercle bacilli, especially in view of the violent tuberculin reaction. The case is one which was also mentioned in a former paper noticed in The Journal of January 23, p. 271.

64. **Anesthesia in Abdominal Surgery.**—Williams insists on the importance of a skilled anesthetist, and thinks the selection of an anesthetic of less importance than the selection of the one to administer it. He has no fear of chloroform in abdominal surgery, and believes that in careful hands it is a safer substance than many believe. In the vast majority of cases, however, ether will be employed. It has the advantage that it is nearly always possible to procure a fresh supply, and so far as statistics go, is safer. The patient can be placed under anesthesia in a large number of cases quite as easily and quickly as under chloroform, keeping the patient in pretty much the stage desired, while with chloroform he has seen the patient go quickly from the sensation of pain to deep narcosis. When we are compelled to place the anesthesia in unskilled hands it is safer than chloroform. When organic heart disease is present, ether for the time stimulates the heart; he has seen the patient leave the table in a better cardiac condition than before the operation. He has administered ether to alcoholics, tuberculous cases, and cases of pathologic kidneys, and thinks it is as safe as any general anesthetic, if not safer. His plan is to administer the ether on a square of gauze of about twenty layers, allowing a few drops to fall on the center of the pad, letting the patient "see what it is like" by holding it several inches from the face. This is followed by a request to close the eyes and breathe as he wishes, but stating the benefits of slow, deep inspirations. Still holding the gauze so as not to touch the face, ten or twelve drops are added, carefully avoiding the eyes; in the majority of cases the amount can be increased every few seconds until thirty or forty drops are added each time, the pad being brought close to the nose and mouth, never covering the eyes, and allowed to stay there during the operation. When the patient has been fully etherized, the anesthesia may be given by dropping ½ or 1 dram over the nose tip every minute or so, or using the "drop method" as in chloroform anesthesia. One very important point is to turn the towel over after each addition in the former method, and every few minutes in using the drop method. Whenever possible he prefers to keep the gauze an inch from the face, allowing a certain admixture of air. This can often be done in acute septic and feeble cases. Unless absolutely necessary never request an anesthetic to be given to any one suffering from an "acute cold." During appendicitis and bowel-stitching operations, vomiting and retching are to be strictly avoided, and a few inspirations of air followed by several drops of fresh vapor will usually overcome this tendency. Heaving of the abdominal wall and efforts to swallow seen early in the administration indicate the attempt to vomit; in this case, push your anesthetic. When occurring late in the operation, the patient needs air; withdraw the vapor, gently push the jaw forward and turn the head to one side. It is proper, Williams says, to inform the operator of failing pulse or respiration. Always withdraw the anesthetic when tapping a large cyst or ascites, and when removing bulky fibroids, keep it withdrawn until the patient shows signs of returning consciousness. The anesthetist's endeavor should be to administer vapor so carefully that the transition from one state to the next is a slow agreeable process, void of all sensation of suffocation. Two points to bear in mind are that the average time is eight minutes and the amount four or five ounces.

65. **Duplex Placenta.**—Lewis describes the condition and insists on the importance of examining the edges of the afterbirth with sufficient care so that one can be assured that nothing has been left behind in the uterus. The membrane should be held up to the light to see whether there are any vessels running off from the margin of the placental disc. If so they

should be traced and the spot where they end scrutinized for evidences of the tearing away of an accessory lobe or a succenturiate portion. If it appears that a piece of any but the very smallest size has been retained in the uterine cavity the hand must go in search of it and remove it.

77 *Early Diagnosis of Cirrhosis of the Liver, Considered from the Pathologic Standpoint. W. W. Ford.
78 *Early Manifestations of Cirrhosis of the Liver Previous to the Appearance of Physical Signs. Charles G. Stockton.
79 Clinical Chemistry of Disease of the Liver. David L. Edsall.
80 Certain Peculiarities of the Inductorium. Colin C. Stewart.
81 Spontaneous Agglutination of Blood Cells of Arthropods. Leo Loeb.

77. **Cirrhosis of the Liver.**—Ford has analyzed the cases of cirrhosis of the liver encountered in the first 500 autopsies in the Johns Hopkins Hospital. He finds that advanced cirrhosis occurred as a direct or accessory cause of death in 49 cases, or 1 in 10. The majority were cases of atrophic cirrhosis in which an excessive fibrous tissue production masked the initial changes. Twenty-nine cases were definitely associated with arteriosclerosis, either alone or in association with primary cardiac disease or secondary heart changes induced by primary sclerotic changes in the kidney. Next in frequency to these cases of arteriosclerosis come the cases of syphilitic cirrhosis of the liver. In 14 cases of syphilitic hepatic disease, interstitial hepatitis occurred in but 6. The other 14 cases of cirrhosis present the most diverse pathologic findings. A few seemed to be associated with chronic infectious processes elsewhere. In some, among other conditions, there was chronic suppuration of the genitourinary tract, cholelithiasis, peritonitis, etc. Only 2 of the whole series were hypertrophic. He next discusses the initial changes leading to interstitial hepatitis, and the evidence of existence of these changes in the 500 autopsies. He found parenchymatous degeneration of the liver cells in 26 cases without any increase in the fibrous tissue. Fatty degeneration was found in 158 cases and fatty infiltration in 18 cases, but apart from the cirrhotic cases there was no increase of interstitial tissue observed. In practically all the cases, with the very few exceptions noted, the cases of beginning cirrhosis of the liver were associated with renal disease, cardiac affections and arteriosclerosis. No case of advanced cirrhosis of the liver has been seen in Baltimore in connection with chronic malarial intoxication. He remarks on the experimental, apart from the clinical, data as to the production of cirrhosis, and says there seems to be little doubt but that alcohol has much to do with the production of the condition, but from the experimental standpoint there is no very reliable evidence that alcohol alone can cause fibrous proliferation. Alcohol of itself is not sufficient to start tissue proliferation. Experimental cirrhosis in spite of all the work that has been done, is only in exceptional cases sufficiently definite to bear searching pathologic criticism. The essential factor in the production of fibrous tissue increase can not be made operative. What that factor is can only be determined clinically. We may eliminate from consideration all syphilitic cases, cases of chronic infection and the rarer cases of anthracotic cirrhosis or of malarial cirrhosis, and the few cases of biliary cirrhosis dependent on disease of the bile passages, and still have left the vast majority of cases of atrophic cirrhosis and a considerable number of cases of beginning cirrhosis in all of which the hepatic disturbances are part and parcel of some more general disturbances of nutrition whose pathologic effects operate on kidney, heart and liver alike, but whose primary etiologic factors are as yet unknown.

78. **The Early Manifestations of Cirrhosis.**—Stockton concludes from a study of the subject that subjecting the question to careful scrutiny and analysis there seems to be no positive data from a clinical standpoint on which a developing hepatic cirrhosis may be predicted.

87 *Dysmenorrhea. Charles L. Bonifield.
88 Address—Need of More Unity Among Members of the Profession. S. J. Sornberger.

82. **Gunshot Wounds.**—Weir's paper describes the type of missile wounds received during the Civil War, noticing a number of interesting anomalous cases and calling particular attention to the contrast between the methods then in vogue and those at present practiced. He also refers to the medical or surgical malingerer, a very striking type of fraud on the government, and mentions his methods of exposing the humbug.

83. **Modern Treatment of Gunshot Wounds.**—La Garde describes his experience in the Spanish-American and South African wars as well as accidental gunshot wounds such as the toy pistol injuries and their sequelæ of tetanus. The character of the lesion in gunshot wounds favors all infections, though tetanus is the most frequent and fatal one. The great danger in military practice is the environment; the removal of lodged missiles has to be forbidden at the front, while in civil practice it is imperatively indicated. The remote consequences of gunshot wounds, thanks to antisepsis and the *x*-ray, have been reduced to a minimum. He considers the fatality of gunshot wounds of the head as great as it was by old arms; glancing wounds are less frequent. The modern projectile is less septic, and chest wounds are considered among the hopeful class at present. In conclusion he calls particular attention to the experimental work in this line; it is only by the results of such that the modern treatment of gunshot wounds can be intelligently formulated.

84. See abstract in THE JOURNAL, xli, p. 1224.

85. *Minus Cylinders.*—Higgins' article is written with the special intent of calling attention to the evils from ignorant prescribing of minus cylinders. He insists that to prescribe glasses properly requires a medical training.

94 Neuralgia and Some of Its Clinical Features. Paul Sanford.
95 Asepsis: Especially in the Practice of Obstetrics. J. W. Graham.

90. **The Rat and Its Parasites.**—Lloyd enumerates the numerous parasites to which the rat is subject, including species of tremotada, cestoda, and nematod worms, many of them in common with man; various protozoa, particularly *Trypanosoma Lewisi;* among the insects, the flea, which has its part in the transmission of disease; among the vegetables, the favus organism. He mentions further the danger from rats in regard to plague, showing from the history how plague may linger in the sporadic form for years in a city, and then under favorable circumstances explode, so to speak, into a violent pestilence. The non-contagious nature of the disease in the stricter sense of the word is emphasized.

91. **Appendicitis.**—Stapler insists that appendicitis is caused through loss of tissue with subsequent infection. This loss of tissue may be caused by capillary hemorrhages due to infectious diseases or overexertion or by foreign bodies. No appendicitis without infection, he says, and no infection without loss of tissue.

99 *Effects of X rays on Lower Animal Life and the Tube Best Suited to Their Destruction Kennon Dunham
100 *An Anopheles Mosquito Which Does Not Transmit Malaria Leonard K Hirshberg

96 **Myocarditis**—In the conclusion of his article Camac emphasizes the following points The normal anatomy and physiology of the heart must be closely studied by the clinician A knowledge of the pathologic anatomy and physiology is also essential His study of myocardial disease must be greatly extended by bedside observation, and to do this there must be an honest limitation of the clinician's conclusions to the evidence at hand The diagnosis must be made in the early stages Even with the best methods, the diagnosis of chronic myocardial disease at least is difficult, and its nature obscure

97 **Periureteral Arterial Plexus**—Sampson insists on and demonstrates the importance of the arterial plexus surrounding the ureter, imbedded in its perimuscular fibrous coats The complete dissection of this plexus for a very short distance, or its partial resection, if combined with ligation of the vessels supplying the vesical end of the plexus, is apt to cause necrosis He insists on guarding this plexus in operations, though experience shows that the ureter can stand a good deal of interference The ureter has been freed for its entire length without necrosis Both the internal iliac, ovarian and vessels of the round ligament have been tied without producing such results On the other hand, when the ureter is dissected free from some adherent mass, even for a short distance, there is danger of necrosis, and this danger is increased after operations on account of cancer of the cervix, where the vessels supplying this portion of the ureter are ligated Other etiologic factors of necrosis are infection exudates, the use of the cautery, the pressure of foreign bodies, such as gauze, stricture, and a lowered general resistance In performing hysterectomy in case of carcinoma of the cervix uteri there is danger of ureteral necrosis in the radical operation Resection of the lower .75 cm of the ureter and implantation of the renal end into the bladder offers the best chance of cure, with less danger of ureteral necrosis in such cases In any operation the periureteral arterial plexus and the ureteral sheath should be preserved The article is illustrated by figures showing the ureteral plexus and its blood supply

99 **Effects of X-Rays on Lower Animal Life**—From his extensive experiments, the technic and details of which are described, Dunham concludes that the best rays to destroy epitheliomatous and sarcomatous cells are those from the lower tube excited by a heavy current with much resistance The closer to the object treated the more destructive the rays Very high tubes have little effect By the use of controls he eliminated as the destructive force any other agency than the *x* ray, and also established the analogy between the susceptible lower organisms and new malignant cells

100 **The Anopheles Mosquito.**—From observations made on the incidence of malaria and the distribution of *Anopheles maculipennis* in the neighborhood of Baltimore, Hirshberg concludes that this species is not usually a conveyor of the malarial organism He thinks the absence of any reference in the literature to the species as having been found bearing parasites is also corroborative Farther than this he does not care to go

2 **Pancreatic Disease.**—Robson's third lecture begins with a discussion of pancreatic cysts, the symptoms of which vary, according to the size and seat of the tumor, though there have been exceptional cases presenting very few symptoms and requiring no active treatment Occasionally excision may be performed Aspiration is more dangerous than free incision and drainage The situation for the drainage must vary according to the circumstances He gives his own experience, and a search through the literature reveals 160 cases operated on, 140 of which have recovered or cure is supposed to have taken place Injuries of the pancreas have been thoroughly written up by Mikulicz Radecki and he passes over them to the subject of pancreatic calculi, which as a rule show no calcium carbonate and are opaque to the Roentgen rays, an important point for the diagnosis As these are generally associated with serious and usually progressive disease their diagnosis is of importance He considers their treatment by sialagogues useless and surgical treatment as probably now offering a chance of cure. He would incise about one and a half inches to the right of the middle line, split the right rectus and lengthen the incision upward or downward as needed If the opening of Wirsung's duct has to be explored the second part of the duodenum is to be incised, the papilla laid open and any

impacted calculi removed. If they are more deeply placed in the ducts, the organ may be explored either through the gastrohepatic omentum or reached through a slit in the omentum, the calculus cut down on and extracted by a scoop or forceps. The hemorrhage must be arrested by ligatures. The duct can be sutured and the incision in the gland brought together by buried sutures, the peritoneal covering being coapted by a continuous suture. If leakage is feared a gauze drain may be inserted. When the duodenum is opened it must be closed in the usual way. The incised papilla need not be sutured. Medical treatment of malignant disease is purely symptomatic. Palliative operations for the relief of cancer and pancreatitis associated with jaundice are useless. Even if the operation is survived life is not very much prolonged. Sarcoma and carcinoma occurring in the tail of the pancreas may be removed with some chances of recovery, and if the disease is primary and no secondary growth or glandular involvement has occurred, great prolongation of life is possible.

4. **Blood and Urine Testing.**—The principle of the method described by Wright and Kilner is as follows: A standard quantity of normal red corpuscles in a measured volume of salt solution of standard strength furnishes a test fluid. The urine or blood serum from which that urine is derived is mixed in progressive dilutions in a capillary tube with measured volumes of the standard suspension of red blood corpuscles. The point is determined at which the urine or serum has been so far diluted as to allow of complete hemolysis with the standard suspension. From these data taken in association with the data obtained on diluting the suspension with progressive dilutions of decinormal sodium chlorid solution, the concentration of the serum and urine is calculated. The quotient obtained by dividing the latter by the former is denoted the excretory quotient. The method of forming the standard suspension of red blood corpuscles is given and a number of cases illustrating the process are tabulated.

5. **Tuberculosis.**—Weber discusses the reciprocal relation between tuberculosis and other diseases, pointing out the association of congenital pulmonary stenosis with a predisposition to tuberculosis from not only the imperfect blood supply, but the defective general development. Amyloid disease of the liver is a very rare complication, but fatty liver is so frequently found that a causal connection between the two diseases is generally admitted. Cirrhosis is not rarely found associated with tuberculosis of the lungs or peritoneum, and in a few cases may be due to tuberculosis itself. Alcoholism is evidently a cause in many cases and kidney disease is a very serious complication, usually the result, he thinks. Gout is rarely associated with pulmonary tuberculosis, and this is possibly due to the meat diet and the more generous fare of gouty subjects. There are, however, marked exceptions to the rule of the antagonism of two diseases in persons addicted to alcoholism, and those with general decrepit constitutions. There is sometimes supposed to be an antagonism between cancer and consumption, but there are a great many apparent exceptions. Cancerous patients, however, are generally advanced in life, and have lived well, which may have something to do with the apparent exemptions. Lymphadenoma tends to become associated with tuberculosis and diabetes mellitus is a very common associated disease. Syphilis has been remarked as having a special antagonism, but the majority of French writers think that it predisposes to tuberculosis by lowering the general condition, and that there is some causal relation between the association of multiple neuritis of the alcoholic type and pulmonary phthisis.

6. **"Corset" Cancer.**—Lucas reports two cases which he thinks demonstrates a site of origin of cancer dependent on the friction of the upper edge of a corset where it crosses the anterior fold of the axilla. He has credited this largely to chronic irritation, but supposing the cancer to be due to an organism from without, rubbing in of the organism might be amply effective. The author referred to other sites of origin associated with irritation or disease, and syphilis also producing injuries sometimes proves to be the fore-runner of cancer. Inoculation and contagion were also considered and the infection theory as well as recent observations showing the pictures of mitotic changes in the cancer cells.

9. **Tuberculosis.**—Owen mentions some of the diagnostic points of early tuberculosis, remarking, first, that many cases do not advance beyond the early stages as shown by postmortems. In case of tubercle attacking the serous membranes and the patient surviving, the tendency toward permanent arrest of the new growth is marked, but in the loose tissue of the lung it is more apt to progress. There may, nevertheless, be intermissions, though the bacillus can still be detected, and these remissions would have attracted more attention were it not for the fact that they have been attributed generally to the treatment given. In most cases of chronic tubercle, therefore, we have a mixed morbid anatomy, some fibrous scar tissue and some caseous material of different dates. The chief physical signs are those of consolidation or the presence of what is called tubular or harsh breathing, change in the voice sounds and dullness on percussion. The hearing of well-marked tubular breathing over the chest wall implies that over the area covered by the stethoscope, the superficial layer, at least, of the lung is enough to conduct the sound to the surface, and at the same time abolish the normal vesicular murmur. The actual depth of the superficial layer is difficult to say, but he thinks it does not exceed half an inch. Harsh breathing, associated with voice changes, however, is still more significant and well marked bronchophony must indicate a rather extensive tract of consolidation. The result of percussion may be less marked and does not always correspond with the actual condition of things; sometimes the affected apex is the more resonant of the two. He advises the use of both light and deep percussion, comparing the results. If it is more marked with the light than with the deep percussion there is probably a thickened pleura. If the reverse obtains it suggests a deeply seated patch of consolidation. The question what consolidation really means is of importance, whether it consists of grey granulations, of fibrous scar or of bronchopneumonic products. Moist sounds during inspiration may indicate granulations, though not necessarily a breaking down of the tissue. Clicks at the end of inspiration are formally diagnostic of tubercle, but they may occur at later as well as earlier stages. Tuberculous crepitations may be accompanied by light, dry and wheezing rhonchi, which differ from the asthmatic or catarrhal type by being more localized, but if neither moist sounds nor rhonchi can be found it does not necessarily follow that the condition is not progressive. A daily rise of temperature and progressive loss of weight are almost formal evidence of advanced tuberculosis, even if the physical signs fail. Cavernous breathing is also mentioned, and it may be noticed even over small cavities, but it may also be heard with the stethoscope brought near the trachea, which suggests caution in its estimation. Pectoriloquy is of less value than cavernous breathing, and is not always heard over small cavities, and may be heard where no cavities exist. The earliest physical sign is usually neither dullness or harsh breathing or alteration in the voice sound, but a local change in the character of the bronchitic rhonchus, which ordinarily does not change.

10. **Tuberculosis.**—Baumler calls special attention to the early involvement of the apices, the loss of weight, the temperature signs, strictly localized and persistent râles of various kinds, fine crepitations heard over a limited area, disappearing or being replaced by coarser râles, etc.

14 *Etiology of Scurvy. Myer Coplans.
15 Cold Weather Mosquito Notes from India—Malaria in Umritzar and Its Causes. (Continued.) G. M. Giles.

14. **Scurvy.**—The incidence of scurvy in the Transvaal in the burgher camps among soldiers and natives is described by Coplans, who can not find adequate proof that the food factor is the cause. The clinical facts also would seem to oppose the contention. The infection, however, seems to occur through the mouth, the general system being involved later and secondarily, but how the primary infection occurs and how it gives rise to disease in the mouth is not capable of being definitely stated and needs further investigation. He thinks the facts adduced seem to prove that scurvy is not due to either the presence or absence of any particular kind of food, but rather to infection for which food may act as a vehicle under conditions of dirty storage or dirty preparation. Considering that the disease prevailed in inverse proportion to the standard of personal hygiene of the individuals infected, the infectivity seems to depend on the sanitary habits and perhaps unwholesome occupations.

20. **Breathing Exercises.**—Rosenthal urges that the profession take personal charge of the physico-therapeutic measures which time is proving of such vast importance. This applies particularly to gymnastic respiratory exercises as a preventive and curative measure for affections of the air passages. He asserts that Knopf in his memoir on the subject in 1901 merely confirmed and realized the ideas which Marfan, Grancher and Jaccoud of France had long been preaching. It is as absurd to breathe through the mouth, he claims, as it would be to eat through the nose. In taking the chest measure he has found it useful to have a tape in which the inches are marked off toward each end from a central point which is placed on the spine. This reveals any asymmetry at a glance. He has found that the diaphragm may be subject to incompetency, inco-ordination or unilateral paresis. This insufficiency of the diaphragm is revealed by the immobility of the lower ribs and interspaces. As the subject reclines the abdominal wall is likewise immovable, with other signs almost simulating pleurisy. Radioscopy will clear up the diagnosis. The subjects for whom respiratory exercises are particularly indicated are the "false adenoidians," and cases of nervous nasal obstruction. Also of pseudo-hypertrophy of the heart in growing children. In the latter case the heart is normal but the chest has not grown to keep pace with it. Exercises in deep breathing are the elective, rapid and specific means of restoring the balance in these cases. He also states that the prolonged course of convalescence after infectious diseases is in many cases due to the lack of sufficient respiration. Appropriate exercises would materially shorten the convalescence. Keeping the patient out of doors is a blind means of accomplishing what is needed, but appropriate exercises are the systematic application of the same principle which is both preventive, therapeutic and for after-treatment. Such exercises are the specific preventive of tuberculosis. In conclusion he comments on the dangers of inertia of the diaphragm, which affects secondarily the functions of the liver, intestines, etc. Every inflammatory affection of the peritoneum near the diaphragm is liable to limit the excursions of the diaphragm, while gaseous distension of the abdomen or its organs or pregnancy has the same effect temporarily, which may, however, outlast the cause.

21. **Zootechnical Side of the Milk Question.**—Diffloth refers to the way in which cows have been bred to produce the maximum of milk, and remarks that this exploitation of the milk-producing function for commercial purposes is contrary to nature, and has perhaps unfitted the milk for the use of infants.

26. **Sterilized Drinking Water.**—The Lepage apparatus is briefly described with an illustration, and its use recommended for barracks, ships, private houses, etc. It boils and cools the water still in the pipes in which it is brought into the building. The water first collects in a tank like that for a water-closet and passes downward in a small pipe. The pipe then broadens to about six times its former diameter and passes straight upward to the level of the tank, opening into a small conical receptacle, the point upward, terminating in a curving pipe. A gas jet below this conical receptacle keeps the water boiling and by expansion it passes on into the curving pipe above whence it drips, a drop at a time, into a much wider part of the pipe, paralleling the upright pipe above mentioned. The boiled water thus stands in contact with the cold water in the first upright, which cools it and it is drawn from a faucet as needed. The illustration shows that the curving pipe is above the level of the water in the first tank, and consequently the water can not pass on unless it is first expanded by the action of the heat under the boiler receptacle.

28. **Treatment by Artificially-Obtained Natural Gastric Juice.**—Hepp was formerly interne of the Paris hospitals and has been meeting with great success in his efforts to supply a natural gastric juice for therapeutic purposes. He obtains it by a Pawlow opening into the stomach of pigs. The gastric juice thus obtained keeps indefinitely after filtration if sheltered from light and air, and has fully established its usefulness in cases of gastric insufficiency, especially those due to dyspepsia from atony, inadequate secretion of gastric juice, in the gastro-intestinal disturbances of nurslings consecutive to acute enteritis, and in the stomach troubles of tuberculous subjects. It has also proved its value in the gastric troubles of chlorotics, of over-fatigued and neurasthenic subjects and of pregnant women. It is generally taken during the meal, one to three tablespoonfuls of the limpid fluid being added to some beverage, beer, lemonade, champagne or some mineral water. It is sometimes best to refrain from telling the patient the character of the medicine he is taking.

34. **Sphygmometer.**—Mladoveano has applied the sphygmograph to determine the arterial pressure at the wrist, and gives an illustration of the instrument modified for the purpose. It supplies a force to crush the artery, indicates when the artery is crushed and the blood current thus interrupted, and registers the pressure. His modification can be added to any sphygmograph and transform it into a sphygmometer without interfering with its other uses.

35. Surgical Treatment of Facial Paralysis.—Munch reviews the experiences in this line in America, France, Germany and Great Britain. The results apparently establish that grafting the facial on some neighboring nerve is capable of restoring a certain tonicity to the paralyzed muscles and thus attenuate the asymmetry of the face in the fortunate cases. But it is unable to restore to the muscles their spontaneous movements, and on the other hand, it entails certain inconveniences which are of some importance, such as associated movements of the shoulder and face. Another disadvantage is the atrophy sure to follow in the muscle innervated by the nerve chosen for anastomosis with the facial—no matter what technic of anastomosis is adopted. In some cases the atrophy of the trapezium or the hemiatrophy of the tongue does not cause serious functional disturbance, but in others the disturbance is not negligible. On the whole, Munch thinks that the disadvantages outweigh the inconveniences of the paralysis of the face, but if surgical treatment is contemplated the evidence is preponderantly in favor of facio-hypoglossal nerve anastomosis instead of the spino-facial graft which entails more serious disturbances.

36. The Knife or "Tapotage" Sign of Cavity in Lungs.—Erni applies this term, "tapotage," which means tapping or slapping, to describe the reaction which he has found almost pathognomonic of a tuberculous cavity in the lungs. He percusses the chest over the apex of the lungs, using for the purpose a flexible knife—a silver paper cutter—weighing about 100 gm. The blade is taken in the fingers and the chest is tapped with the handle, no force being applied, but merely the elasticity of the knife doing the percussion. The handle rebounds as it touches the chest wall. This light percussion produces no effect over normal parts, but when there is a cavity beneath, the percussion causes the subject to cough immediately and expectorate, all in less than a minute. If the same point is percussed several times an ecchymosis forms if there is a cavity beneath, but not otherwise. The cough and expectoration with which the cavity reacts to the percussion have therapeutic value, as they clear it out. The amount of sputa expelled is also an indication of the size of the cavity. Erni has been studying this sign for nine years and has always found it positive when there was a cavity located near the surface. He has also found this knife percussion an important aid in clearing out a cavity. The sputa become mucous and then dry up entirely as the cavity heals after evacuation; the walls become thicker and the tapotage sign can then no longer be elicited.

39. Suspension of Testicle in Treatment of Varicocele.—Carta suspends the testicle from the pillars of the external inguinal ring, using for the purpose a musculo-fibrous bag formed out of the cremaster and vaginalis. This allows excision of the varicosed veins and averts all dragging on the cord. The results have been perfect in 22 patients on whom he has operated by this technic during the last fifteen months. The technic is described in detail.

41. Disturbances from Adhesions and Peritoneal Bands.—Lejars does not include postoperative adhesions in this study, but merely those which have no appreciable source or have long survived the primary cause. Such adhesions and bands may entail trouble manifested solely by pains and vague functional disorders; or they may induce strangulation of the intestine, in all its forms, or a clinical picture reproducing in every particular the syndrome of this or that distinctly characteristic abdominal affection. He relates a number of examples of gastrointestinal disturbances following, after a longer or shorter interval, some apparently slight traumatism affecting the abdomen. The most prominent symptoms were vomiting, pains, tenacious colics and attacks of pseudo-occlusion, all of which subsided after a simple exploratory laparotomy and detachment or excision of the adhesions or constricting bands. The feature of these cases is the long interval that may elapse before any disturbances are noted. It is sometimes difficult to trace back to the primal traumatic cause of the disturbance. When no traumatism can be discovered in the antecedents the diagnosis is more difficult and the rebellious colics, vomiting, constipation or diarrhea are liable to be attributed to visceralgia or some other mysterious neurosis, when in reality the sole trouble is some peri-intestinal adhesion or restraining band. Lauenstein reported nine years ago 9 cases of this kind, and Lejars here analyzes 2 from his own experience. In one a woman of 30 had suffered from abdominal troubles for fifteen years, attributed to ingestion of a caustic. The pains grew worse and worse, mostly located in the left side, and were accompanied by nausea and vomiting. For a long time the patient had been fed exclusively by the rectum. Signs of pseudo-occlusion were observed at intervals. The patient had become addicted to morphin as the condition had only become aggravated under the various methods of treatment applied. An exploratory laparotomy disclosed a band of omentum constricting the transverse colon and another crossing the cecum. Both were excised and there has been no recurrence of the disturbances. The second patient was a woman of 40 who had had stomach trouble for thirteen years, distinguished by vomiting and pains exaggerated when standing erect, located to the left of the umbilicus. A cicatrix about the size of a quarter was found in the anterior wall of the stomach. This organ was adherent to the liver, and a broad band, about three inches long, fastened the cicatricial and adherent portion of the stomach to the wall of the abdomen. After excision of this band the patient was cured. These bands are probably the relics of some long extinct inflammatory process, the symptoms of which were unnoticed or have been forgotten—which explains the difficulty of a proper diagnosis. Perman has related an instructive case of a congenital band of this kind. The patient was a young man who had suffered from frequent colics since he was 8 years old. The pains developed especially after eating and after physical exertion. The condition grew constantly worse and a small umbilical hernia was incriminated. As long as the subject remained confined to his bed he had no disturbance, but as soon as he got up the pains recurred, severer than before. Each attack lasted from twelve to fourteen hours and terminated suddenly with passage of flatus. The abdomen was opened and a round cord as large as a penholder was found extending from the umbilicus to the lower portion of the sigmoid loop, where it spread out into a fan. A complete cure followed its excision. The symptoms caused by these adhesions or bands are gastric, intestinal or pelvic. They testify to the presence of some obstacle and to a painful distension above the obstacle. The lack of response to medication and the exacerbation in certain attitudes are aids in differentiating. The subjects are liable to become neurasthenic, but this phase is secondary. A settled pain, recurring always in the same zone, usually can be traced to some real, mechanical and curable cause. In the pelvic form the pains in the pelvis, sacral or iliac regions recur also in attacks, usually coinciding with the onset of menstruation. The organs are sound and the adhesions are due to some old, long past pelvi-peritonitis. The appendix may have co-operated in its production, but the main point is that all disturbances cease as soon as the adhesions are detached or excised. In one of Gersuny's patients McBurney's point was painful, but so was also a corresponding point in the left side. There was constipation and this aggravated the pains, which amounted at times to severe colics. Enteroptosis, chronic constipation and pelvic neuralgia had been diagnosed in turn, but a laparotomy disclosed merely adhesions. Intervention must be complete in such cases, with multiple and integral liberation. We know that about a third of all cases of strangulation of the intestine are due to constricting bands—too often attributed to mere constipation. Lejars witnessed the death of a young man from this cause. There had been no vomiting, very little distension, some flatus still passed and after a week of expectant treatment the exploratory laparotomy revealed a mass of adhesions fastening the sigmoid flexure and part of the small intestine to a large cicatrix on the abdominal wall. One peculiarity of this class of occlusion from the multiple adhesions is that they fail to cause trouble for such a long time, but when it does develop it is serious. In another case, for instance, a man of 66, large, fat, diabetic, had never had any intestinal disturbances of any kind except for a vague history of a brief painful affection of the epigastrium twenty years before. Suddenly pain developed in the left hypochondrium and flank, and there was considerable meteorism above the umbilicus. The rectal evacuations still continued and there was no vomiting. Medication for several days did not improve the condition, the meteorism and constipation increased and the pulse showed trouble. An adherent and compact mass of intestines was found above the umbilicus, involving the transverse colon and small intestine. The patient died in coma in a few days. In conclusion Lejars reviews a large number of cases that have been published in which the constricting bands caused a syndrome simulating that of ulcer of the stomach, cholelithiasis, cancer, etc., calling especial attention to some cases of occlusion of the common bile duct by adhesions alone. As these conditions require operating in any case, differentiation of these relics of inflammation is not so important. The unexpected success of many of these purely liberating operations is most encouraging. They may require a slow, progressive, minute dissection and the adhesions must be extirpated as completely as possible to guard against recurrence of trouble. If integral liberation is impossible it is preferable to establish some roundabout route by anastomosis rather than to excise the wall of the stomach or intestine.

43. **Ultramicroscopic Study of Cause of Sympathetic Ophthalmia.**—Raehlmann has been applying the perfected ultramicroscope to the study of metastatic inflammation and gives illustrations of the findings in a case of phthisis bulbi requiring enucleation. The eyeball was examined under a microscope magnifying 2,400 diameters. The vitreous body was found swarming with motile bacteria apparently all of the same kind and representing what he believes to be the first instance of the direct inspection of a pure culture of living bacteria in the interior of the tissues. These bacteria are less than .25 of a micron in one diameter, but are longer in the other, too large to pass through the vessel walls like the particles of albumin, which is also prevented by their lively motions. It is possible, however, that the younger forms are still smaller and are thus able to pass through the vessel walls. This assumption would explain the cyclic character of certain inflammations. It would also explain sympathetic ophthalmia. The primary injury of the eye allows the proliferation of these bacteria in the vitreous body for which they seem to have a predilection. This process remains latent, that is, restricted to the vitreous body, until the birth of another generation. The very small younger forms pass readily into the blood and thus the first condition for the formation of metastases is produced. They circulate in the blood until they reach the vitreous body in the other eye. The vitreous humor as a watery fluid containing very little albumin is unique in the organism, providing a culture material unlike anything to be found elsewhere in the body. Hence, it follows that the bacteria circulating in the blood, if they are not eliminated by the natural emunctories beforehand, find conditions favorable for them in the vitreous humor and consequently locate there, and there alone. His research has further shown that the primary and sole location of the penetrating microbes is in the vitreous body. The inflammation spreads thence to the ciliary bodies and the iris and backward to the optic nerve, but this is merely the inflammatory reaction of the surrounding tissues, not due to the direct action of the bacteria, as none was found in these parts. Sympathetic ophthalmia is, therefore, a metastatic infection of the second eye induced by ultramicroscopic micro-organisms. The interval before the invasion of the other eye may vary with the virulence, number, etc., of the germs. He does not think that it can occur under six weeks, but is liable at any time after this, even after several years. The inflammatory reaction in the surrounding tissue is probably the effect of the products of bacterial metabolism, and may extend a long distance from the located microbes, but we have no reason for assuming that this inflammatory reaction alone is able to induce a sympathetic ophthalmia.

44. **Action of Radium Rays on the Eyes.**—Greeff discusses the fact that the rays of radium are visible to the naked eye in the dark. It is not a phosphorescence, as radium maintains this property indefinitely when kept exclusively in the dark without exposure to any light. It induces fluorescence in other objects and also emits the radium rays proper. He experimented with a mixture of both barium and radium chlorid, containing about .02 gm. of the latter. The paper in which it was wrapped became fluorescent under its influence, as also the fluorescent screen, but the light thus emitted is the ordinary light of fluorescence. Not so the light induced by the direct application of the radium to the eye. The radium mixture, enclosed in a leather box, to eliminate all phosphorescence, is approached within 10 cm. of the eye, which then perceives a diffuse sea green light, increasing in intensity as the radium is brought closer to the eye. It is impossible to locate the source of the light, as it is diffuse, and the intensity is the same whether the radium is held above or at the side of the eyes, or whether there are interposed objects, eyelids open or shut, the hands held over them, or even the interposition of a steel plate. The radium rays penetrate readily every substance known to date, with no attenuation, in which they differ from the Röntgen rays. Himsted and Nagel explain this action of radium on the eye by assuming that the radium induces fluorescence in certain tissues of the eye, and that this fluorescence is perceived as a light by the retina. Greeff examined the various parts of pigs' eyes to determine their power of fluorescence in these conditions and found that it was actually less than that of the surrounding skin, but that the radium did not bleach the visual purple in the retina in the dark, thus excluding the possibility of a direct light action on the retina. He consequently inclines to accept Himsted and Nagel's theory. No injurious effect on the eyes was perceptible from these experiments with radium radiation. The sensational announcements that with radium the blind can see are disproved by the above statements. Persons with relics of vision may be able to see the outline of dark objects placed on the fluorescent screen lighted up by the radium rays, but the same effect is obtainable with any screen and kerosene lamp. The same persons may be able to perceive, like the sound eye, the diffuse greenish luminosity induced by the radium rays proper, but this is far from actual seeing. Nothing has been advanced to date which encourages any hope that radium will enable the blind to see. London's announcement that with the radium rays the blind are able to see was mentioned in The Journal, xli, page 400.

45. **Action of Radium Rays on Carcinoma in Mice.**—Apolant gives the results of radium treatment of a number of mice which had been inoculated with scraps from extremely malignant carcinoma in man, according to the Borrel and Jensen technic. The communication proceeds from the Institute for Experimental Therapy at Frankfurt, in charge of Professor P. Ehrlich. The mice were the seventh or eighth generation of inoculated animals. Out of 19 tumors, the size of a pea to that of a large bean, 11 retrogressed completely under the influence of the radium rays and the remaining 8 were reduced

to mere traces of the former tumors. The growths began to retrogress before even the effect of the rays was shown in the falling out of the hair. *On the other hand, the controls showed* enormous increase of the tumors with 6 exceptions, in which the tumor remained *stationary* or was spontaneously absorbed, as occurred in 2 cases. The findings in both sets of animals are shown *in parallel* illustrations which present a graphic picture of the invariable success of the radium radiation, with details of its application. The radium was applied directly over the tumor, in light contact with it. The duration of treatment ranged from six to twenty-three days, during which time the radium was applied *from two to fourteen times*, each sitting from five to twenty minutes long. The few instances *in which after the tumor had* retrogressed to mere traces and stopped there, notwithstanding repeated and more vigorous radiation, the time and exposure limits above were much exceeded. The refractory behavior of the tumor at this point was probably due to transformation of a certain part of the growth into connective tissue.

47. **Determination of Position and Outline of Heart with X-Rays.**—Grunmach *gives an illustration of an improved* vacuum apparatus for *x*-ray work. With it he has succeeded *in distinguishing* three classes of "heart neurasthenics," as he calls them: 1, those with heart of normal size and position with slightly increased pulse rate and regular rhythm; 2, those with normal pulse rhythm and no dilatation, but with a displacement of the heart downward and sideward by cardioptosis, and 3, those with a slight enlargement of the heart, the pulse rhythm periodically transiently irregular, bigeminus or trigeminus, easily restored to normal by massage of the heart. Conditions remain normal afterward for days with rest and hydrotherapy, but under stress *of excitement* the pulse becomes irregular again. It can again be restored to normal by massage of the heart and may persist normal under repose and hydrotherapy. The slight enlargement of the heart, however, remains uninfluenced by all these measures. The practical results of his numerous experiments and findings center in the maxim that the old, tried heart remedies are not to be discarded in favor of the newer hydrotherapeutic measures in treatment of heart disease, but should be combined with them in appropriate cases. He urges *x*-ray examination of all cases of heart disease before applying hydrotherapy for fear that a *latent or incipient aneurism of the aorta may* escape our other modes of investigation. It is sure to be aggravated by the hydrotherapy. *He found that the outline of the heart in* healthy subjects never varied under the hydrotherapeutic measures nor under unusual exertion nor immoderate use of alcohol nor hot baths.

49. **Thiosinamin Treatment of Contracture.**—Lengemann reports additional cures from the injection of thiosinamin in cases of Dupuytren's contraction, and states that the fine results obtained have been permanent for more than a year since. He gives an illustration of still another case, the patient a man of 35, *the contracture of ten years' standing. About forty* to forty-five injections were made in the course of seven or eight weeks and normal flexibility was restored. *Similarly* fine results were obtained in the case of a traumatic contracture of the thumb, which regained its normal excursions after 25 injections. He always injects the fluid directly at the point where its action is desired, first injecting cocain, and follows with massage, passive movements and application of a dressing saturated with the thiosinamin.

51. **Thermometer That Can Be Boiled.**—Kantorowicz has improved on the ordinary clinical thermometer by having the upper end of the mercury tube spread out into a reservoir large enough to contain ten times the bulk of the mercury in the thermometer. The instrument can thus be placed in boiling water without fear of injury or even be sterilized with steam. For convenience he calls it the "pyrol thermometer."

64 Anurie infolge doppelseitige Nieren-Nekrose, verursacht durch Druck-Erhöhung in den Nieren. J. H. Saaijer (Leyden).

56 and 57. **Experimental Decapsulation of the Kidneys.**—Asakura has performed on rabbits and dogs Edebohls' method of decapsulation of the kidney. The operation was always well borne. *A new envelope of connective tissue formed around the* decapsulated kidney and new blood vessels formed in the new capsule and on the surface of the kidney. *Animals with a* suppurating kidney were also treated in the same way, but *with less success, although even after injection of* staphylococci into the vein of the ear the course of the infection was *more favorable in the decapsulated animals than in the con*trols. Stursberg's experiments in the same line on rabbits and dogs, both healthy and under the influence of potassium chromate, were equally favorable in regard to the effects of decapsulation or nephrorrhaphy. The decapsulation was always followed by a new formation of vascular communication between the kidney tissue and the adjacent tissues, which apparently had an essential influence on the ample supply of blood to the kidney.

58. **Technic of Lumbar Puncture.**—Klein *gives a number of* diagrams of the lumbar intervertebral spaces as seen by radioscopy *in the cadaver—not studied from the skeleton.* The conclusion is evident that in the third and fourth lumbar intervertebral spaces the conditions are most favorable for lumbar puncture. The lumbosacral spaces are broader but much lower, sometimes so low as to afford very unfavorable conditions. The general skeleton is no criterion as to the size of the spaces between the vertebræ.

59. **Spontaneous Appendicitis in Animals.**—Mori found spontaneous appendicitis in two rabbits and one dog. In one rabbit there was proteus, coli and staphylococcus infection, in the others coli alone. He was able to induce an artificial appendicitis by injection of bacteria into the arteria appendicularis.

60. **Artificial Infection of Biliary Passages with Pneumococcus.**—After extensive resection in dogs of the common bile duct, freshly virulent pneumococci from sputa were injected into the gall bladder. The cocci vanished from the bile, but circulated in the blood, and in the stagnating contents of the gall bladder obligatory anaërobics were found in great numbers. These findings explain the absence of pneumococci in the gall bladder of pneumonia cadavers. None of the animals displayed any pulmonary lesions notwithstanding the pneumococcemia *and not even after exposure to cold.*

61. **Operations on Diabetics.**—Körner reviews 38 operations on diabetics undertaken on account of mastoiditis. In mild cases the sugar in the urine was increased but only temporarily. Only in the very severe cases is coma to be feared. An otherwise indicated operation need not therefore be omitted on account of an existing mild diabetes, but *in the severe* cases no operations should be undertaken unless under vital necessity. The details of the 38 cases are tabulated. He selected the cases of mastoiditis as affording conditions for better comparison. Only 7 of the total number were personally observed by him; 27 have already been published, and 4 were communicated by Kümmel.

62. **Invagination in Children.**—Kredel operated on 8 out of 12 children with acute invagination of the intestines. Only one recovered spontaneously, and all the others died. All but 2 were less than one year old. He urges prompt intervention and special efforts to avoid shock. *In severe cases he advises* to ligate the mesentery and make an artificial anus, or pos-

bly restrict the intervention to suturing to the incision the rst distended loop that comes to hand, opening it to allow racuation of the contents. Rapid operating is the only hope; he second day is usually too late. The indications are as ressing as for incarcerated hernia. Enemata and insufflation f air are dangerous.

74 Die Schlaftänzerin Mme. Magdeleine G. im aerztlichen Verein zu München. F. Schlagintweit.

65. **Bilateral Vagotomy.**—Starck describes experiments on dogs in which the vagus was interrupted by stages, from the diaphragm to the neck. The technical difficulties were great. He did not find that the vagotomy had any influence on the esophagus at the time nor during the interval of more than nine months since.

66. **Destruction of Tubercle Bacilli in Milk.**—Rullmann found that the tubercle bacilli were still alive and virulent in milk heated to various temperatures for various periods of time, but never when the milk was heated to 68 C. (156 F.) for one hour, during which it was kept in constant motion. The taste of the milk and the chemical condition of the constituents of the milk are scarcely at all affected by this temperature, while the extremely virulent bacilli were all destroyed. He, therefore, commends this method of sterilization as perfectly effective while free from the objections of other technics.

68. **Continuous Gastrosuccorrhea.**—Bittorf distinguishes between the primary idiopathic form of chronic, continuous gastrosuccorrhea (Reichmann's disease), and the secondary form, accompanying dilatation of the stomach, ulcer, stenosis or catarrh. The idiopathic form is a neurosis, a disease *sui generis*, extremely rare. There is also an idiopathic variety which occurs only at intervals, as also a secondary form of this kind, secondary to hemicrania, tabes or brain affections. The idiopathic form may exist for years—seven years in one instance—and he describes a case in detail that had lasted for three and one-half years. Treatment includes sodium bicarbonate or magnesia, meat diet, frequent meals with tonics, hygiene and mild hydrotherapy. Treatment along these lines may not only relieve the symptoms, but realize a complete cure. There is evidently an excessive increase of the physiologic amount of gastric juice from morbid irritability of the secretory nerves. This irritation may be due to swallowed mucus from the throat, which is liable to induce the physiologic secretion in the empty stomach. The literature is reviewed.

70. **Secretory Neurosis of Intestines.**—Geissler's patient occasionally secreted large amounts of pure intestinal juice. He had long been subject to gastrointestinal disturbances and then acquired neurasthenia and exhibited symptoms of disturbance in the innervation of the intestines, manifested chiefly in the secretion of abnormal amounts of intestinal juice, causing diarrhea. The nervous character of this diarrhea was unmistakable. It only occurred after nervous strain or excitement and the feces showed exceptionally fine digestion. When the food passes rapidly through the digestive tract, as in ordinary diarrhea, it does not have time to undergo proper digestion.

86 Zur Kasuistik der Mesenterial-Varietäten. A. Neudorfer (Gersuny's service, Vienna).

76. **Pneumococcus Peritonitis.**—Ghon describes the pathologic anatomy of 4 cases of acute fibrinous-suppurative peritonitis originating in the stomach. The pneumonia diplococcus was found numerous in the exudate, sometimes alone and sometimes associated with other bacteria. The subjects were 23 to 69 years old. In 3 cases there was a carcinoma and in the fourth an ulcer in the stomach. A fifth case showed a similar picture after perforation of a gastric ulcer. There was a lung affection in 2 of the cases only. In conclusion Ghon suggests that disinfection of the mouth and nose might prevent infection from this source in gastrointestinal operations, and might possibly reduce the mortality still further. A. Fraenkel long ago insisted on disinfection of the nose as an important factor in treatment of injuries of the skull.

77. **The Reverse Side of X-Ray Treatment.**—Riehl exhibited a patient at his local medical society, March 4, who had been treated for chronic eczema by exposure of the parts, once each, to a soft tube for half an hour—a total of ten sittings. The regions involved were the neck, breast and arms. The eczema temporarily disappeared, but in its place extensive gangrene developed. It healed, but ulcerations recurred at times. A year after the *x*-ray treatment the exposed patches assumed a different aspect, with atrophy and telangiectasia, resembling a "fire mole," while the skin contracted until flexion of the elbow is reduced by one-third. The chronic eczema has returned and involves previously intact regions. The patient has thus been permanently disfigured by the treatment. Riehl also knows of a number of women who had the *x*-rays applied as a depilatory for the chin and upper lip, and atrophy and telangiectasia have developed not only over the spot, but extending down even to the nipple in certain cases. No remedy has yet been discovered to cure this telangiectasia. He warns in conclusion that pathologically altered skin is liable to react to the *x*-rays in a different manner from sound skin. He thinks the hour has come for radiologists to collect and publish their successes and failures, like the surgeons. He also insists that radiologists should be trained dermatologists to begin with, and that cutaneous affections which we are able to cure by other means should not be submitted to *x*-ray treatment. Even in lupus the results have only been temporarily favorable, on the whole.

78. **Simple Blood Test for Typhoid.**—This communication from Gluzinski's clinic at Lemberg is another highly favorable report on Ficker's ready-made diagnosticum for the typhoid agglutination test. See editorial on page 962.

82. **Inoculation of Animals' Brains with Carcinoma.**—Wagner found that animals tolerated the injection of cancer substance as a foreign body, but succumbed to infection from the pathogenic germs accompanying the implanted scraps. The research was undertaken to disprove Adamkiewicz' assertion that the simultaneous injection of cancroin with cancer scraps prevented the latter from developing. Both cancroin and cancer scraps were incorporated like a foreign body, exerting no specific effect either alone or together, and the death of the animals was due to casual infectious germs or in their the animals was due to casual infectious germs, and in their

83. **Intra-Auricular Transplantation of Thiersch Flaps After Evacuation of Middle Ear.**—Politzer accelerates healing after

a Panse or Körner plastic operation by transplanting Thiersch flaps when the surface is granulating, about the sixth to the twentieth day. He irrigates the ear with sterile water for several hours beforehand, then fills it with 6 per cent. hydrogen peroxid, and then after five minutes, dries and tampons with cotton. Three or four hours later he proceeds to the transplantation. He takes the flap from the inside of the thigh or arm, about 1 or 2 square centimeters in size, and applies it on the perforated tip of a canula, of which he gives an illustration. There are a dozen or more openings in the tip of the canula, the other end of which swells to form a sphere just before it is attached to a rubber tube and bulb. The flap is placed on the tip of the canula and the latter is then introduced into the ear, and when the flap is over the proper location it is blown on it by pressure on the bulb. The ear is then packed with small cotton wads, avoiding pressure on the flaps. He describes the technic in detail, and states that it has been followed in 12 cases to date in his clinic. In 5 cases healing was perfect. In 5 others partially so, and the 2 others were failures at first, but one healed after a second transplantation.

85. **Permanent Alterations in the Skin After Roentgen Radiation.**—Freund and Oppenheim describe the disagreeable after-effects of *x*-ray treatment as observed in certain cases. They give illustrations of the histologic findings in one case of pronounced telangiectasia, and proclaim that these troubles are unmistakably the result of the disturbances in the circulation induced by the exposures. It is particularly liable to occur when the action of the rays is most intense in the upper layers of the skin. The existing capillaries of the upper network of capillary vessels become dilated, and pre-existing cutaneous affections in which there is already a tendency to this dilatation of the vessels afford a predisposition to telangiectasia later which must never be forgotten. Besides telangiectasia the *x*-rays are liable to induce atrophy of the skin and an alteration in the skin suggesting scleroderma. The findings in each form are described. In the telangiectasia they simulate those of commencing xeroderma pigmentosum. The torpid character of the Röntgen ray dermatides is due to the chronic stagnation in the vessels of the cutaneous region exposed. The ulcers developing on account of the necrobiosis of the tissues display the same torpid character and lack of tendency to heal which distinguish varicose ulcers in the leg. The conditions are practically the same in both these lesions. The effects observed indicate the necessity for using rays which affect the deeper tissues and do not exhaust their energy on the superficial layers.

98 *Value of Olive Oil in Affections of Stomach and Duodenum. P. Cohnheim.—Weitere Mittellungen über die Heilwirkung grosser Dosen von Olivenöl bei Erkrankungen des Magens und des Duodenums, Ulcus, Hyperchlorhydrie, spastischen und organischen Pylorus-Stenosen und deren Folgezuständen (Gastrektasie).

99 Cancer Research. G. L. Mamlock (Berlin).—Krebsforschung im Zeitalter der Aufklärung.

88. **Dysentery.**—Jürgens expatiates on the occurrence of latent symptomless cases of typhoid and dysentery as the connecting links between epidemics. He also comments on the unknown factors which induce epidemics. The bacilli alone are not sufficient. The locality seems to exert a marked influence. His experience with infected troops changing from garrison to garrison confirms this.

89. **The Glycogen Problem.**—Wolff comments on the varying solubility of the glycogen of normal leucocytes in health and disease and in different species. He further states that the idea that glycogen in the leucocytes indicates a degenerative process is incorrect. It was based on imperfect technic. On the other hand, later researches have shown that a lesser water-solubility of the glycogen in the leucocytes indicates a degenerative process.

95. **Paroxysmal Hemoglobinuria.**—The origin of the hemoglobinuria in the 3 cases described was not from the direct action of cold on the red corpuscles, nor from a purely mechanical injury to these corpuscles, but seemed to be due to a hemolytic action of the blood plasm. This hemolysis is probably the result of the action of the serum hemolysins.

96. **Typhoid Fever.**—Jürgens reiterates that the presence of the typhoid bacilli is far from being synonymous with the disease. In the efforts to carry out Koch's method of isolating typhoid patients, all the persons in the family were examined for typhoid bacilli, regardless of whether they were sick or well. This revealed a number of slight, atypical cases of typhoid and also disclosed the presence of the bacilli in certain absolutely healthy subjects. The bacilli in the milder cases were sometimes far more virulent than in the severe ones. The resistance of the individual is evidently the determining factor. The disease process is identical for all, but differs in its degree. Other points in Jürgen's communications were reviewed in an editorial on page 959.

97. **Albumin in Feces as Sign of Functional Disturbance.**—Dissolved albumin was always found in the feces of healthy nurslings, but only rarely in healthy older children, but always in both in case of an intestinal affection. In adults it was found only in a certain proportion of the cases of severe intestinal affections.

98. **Value of Olive Oil in Gastrointestinal Diseases.**—Cohnheim's article was reviewed in an editorial on page 895. In addition to the points therein noted may be mentioned his recommendation of an emulsion of almond oil in case there is repugnance to the olive oil. It answers the same threefold purpose with the exception that it is less nourishing. He has found the olive oil effectual in relieving and curing gastrectasia not due to an organic obstacle, and even in organic and relative stenosis it proves a valuable lubricant. In such cases he orders a wineglassful—two tablespoonfuls—half an hour to an hour before meals, two or three times a day. It has no by-effects, and has frequently rendered a contemplated operation unnecessary. It prevents impending gastrectasia and wards off recurrences. He gives the particulars of 35 chronic cases treated with the oil. A further advantage is that it serves to differentiate purely nervous or hysteric gastric affections, as they are not benefited in the slightest by the oil, in marked contrast to other affections of the stomach and duodenum.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

CESAREAN SECTION FOR PLACENTA PREVIA.

JOHN B. DEAVER, M.D.
Surgeon-in-Chief, German Hospital.
PHILADELPHIA.

Resort to cesarean section as a means of delivery for a patient with placenta previa is still a sufficiently rare procedure to make the history and result of every case a matter of general interest.

For conservative cesarean section for other conditions the mortality for the mother is about 10 per cent., and that for the fetus from 5 to 10 per cent. The mortality for the mother with placenta previa, treated by means other than cesarean section, is about 11 per cent., while the fetal mortality is from 45 to 50 per cent. Gillette[1] collected 216 cases of placenta previa, of which 34 mothers and 96 fetuses died, being 15.3 per cent. and 44.3 per cent., respectively. Schauta[2] reported from his clinic 234 cases, 16 mothers (6.8 per cent.) and 127 fetuses (54.3 per cent.) perishing.

The conservative methods of packing the vagina with gauze or with the dying infant's body, have been fairly successful in averting death from the mother, by compressing the bleeding placental site. The method of rapid extraction after forcible dilatation of the os, where this is required, places the mother in greater jeopardy, but increases the chances of delivering a living child. It is, therefore, on simply *a priori* grounds, to be assumed that a resort to cesarean section would greatly lessen the mortality of the fetus, while not materially increasing the danger of the mother.

Against this reasoning is argued, first, that the mother's life is of much more consequence than is that of the unborn infant. A weighty objection to this is the fact that neither the surgeon nor the accoucheur is a legal executioner, even were he competent to judge between the intrinsic value of the two lives, each of which is equally under his care. Secondly, it is said that the infant whose placenta is previa, is almost of necessity premature at the time of delivery, and is, therefore, very apt indeed to die in a very short time. Again, it may be rejoined that it is neither ethical nor safe for the attendant to act on the principle that his patient will die soon under any form of treatment, and that, therefore, it is little matter what that treatment may be, for it is the bounden duty of every physician to do what he thinks is for his patients' best interests, irrespective of other considerations. Moreover, while the mortality of premature infants in general is about 22 per cent., as calculated by Ford,[3] that of infants in cases of placenta previa treated by rapid extraction is about 55 per cent., and with slow extraction (practically allowing the fetus to die during delivery) this figure rises to 67 or even 83 per cent. "The methods of treatment in placenta previa, therefore," adds Dr. Ford, "are clearly responsible for the loss of 45 per cent. to 61.4 per cent. of the children," and although the prospects from conservative delivery may have brightened somewhat within the past decade, yet it still seems probable that the fetal mortality is in this affection disproportionately high.[4]

The danger to the mother in placenta previa is chiefly from hemorrhage, and this hemorrhage, it is to be recollected, is due to premature detachment of the placenta from the lower uterine segment, opening up the uterine sinuses, so that the blood which should pass into the placenta, and so on to the fetus, rushes forth through the dilating os. The fetus meanwhile is becoming asphyxiated. A remedy for the former condition can not be found until the uterus is allowed to contract, and this can not take place until the child is removed, and only by the removal of the child can its asphyxiation be prevented; hence, removal of the child is the first indication. To secure this *per vias naturales* it is necessary, first, to increase the bleeding by separating the placenta sufficiently to allow the introduction of the obstetrician's hand for the performance of version; and while these manipulations are taking place, and the mother is bleeding more profusely than ever, the child is smothering within the womb.

It becomes, therefore, a question demanding the highest judgment to determine whether the mother will endure the added hemorrhage, and whether the fetus will survive the period of asphyxiation, momentary though it be.

In primipara, and in multipara whose os is rigid and undilated (a condition not so rare in placenta previa as has been supposed by some authors), rapid obstetric delivery is no easy task, and the lacerations of the maternal soft parts and the shock to both mother and child may be considerably more than would be entailed in a cesarean section. In other cases, where the os was already dilated, or was soft and easily dilatable, and where the parturient canal was roomy, version and rapid extraction would no doubt offer equally good chances of success.

If labor had already lasted some time, and there was probability of uterine infection, I am not sure whether a Porro-cesarean section might not give the best ultimate results; but the general opinion of the profession appears to be that in infected cases cesarean section is to be avoided.

---

[1] The Journal A. M. A., Aug. 24, 1901.

[2] Interstate Med. Jour., St. Louis, April 1, 1902.

[3] Amer. Gyn. Jour., 1892, ii, 525.

[4] Higgins, in the Boston Med. and Surg. Jour., 1902, i, 6, states that at the Paris Maternity the mortality for premature infants is over 70 per cent., and that at the New York Nursery and Child's Hospital it is 60 per cent. These figures seem scarcely compatible with his other statements to the effect that the fetal mortality in placenta previa is from 50 to 60 per cent. only, while at the same time 62 per cent. of such infants are premature.

If no evidences of fetal life exist, it would, of course, be mere folly to perform cesarean section, since craniotomy or embryotomy would offer a perfectly satisfactory solution of the difficulty in cases where normal delivery proved impossible. On the other hand, if the mother were evidently moribund, a rapid cesarean section should by all means be preferred, if the fetus was still living and viable.

In a private house, where, in case of emergency, the attendant has no skilled assistance, and is unable to have his patient immediately removed to a hospital, it is my opinion that version and extraction would be the better treatment. If the case were not urgent, an efficient vaginal tamponade should secure time enough for preparation for cesarean section; but it is a rule that may well be called golden for the surgeon not to leave his patient's side; once labor has commenced, until she has been delivered. At any moment a torrential hemorrhage may occur, and the mother die like a flash.

In the recent literature a great number of articles may be found,[5] whose writers support one or the other side of this question, and which the reader who desires a fuller exposition of the subject will do well to consult.

The case which I report was referred to me by my friend, Dr. Charles E. Bricker, after consultation with whom I selected cesarean section as the lesser of the two evils, and as an operation with whose technic I was more familiar, and, therefore, one with which I was more likely to have success than with podalic version under such unfavorable circumstances.

History.—Mrs. W., aged 41. Family history negative. Always enjoyed good health. Digestion good, bowels constipated. Married 21 years, four children living and well, one miscarriage five years ago. Patient has always had difficult forceps labors.

Last menstrual flow May 29, 1903. Dec. 20, 1903, she had a severe hemorrhage and was obliged to go to bed, since which time she had felt weak and would become very tired on slight exertion.

Thirty-six hours before admission, morning of Feb. 6, 1904, to a private room at the German Hospital, the patient had a very severe hemorrhage and the vagina was packed with cotton by Dr. Bricker.

Examination.—On admission patient is very well nourished, heavy, fatty abdominal walls, abdomen very large, patient is restless, pulse rapid and thready, mucous membranes pale. Fetal heart sound can be heard on the right side near the umbilicus. Vaginal examination shows the os to be dilated to the size of a silver half dollar and filled by a soft mass. Diagnosis: Placenta previa centralis.

Operation.—Feb. 6, 1904. Incision through the right rectus muscle, peritoneum opened, enlarged uterus was delivered through the incision and intestines protected with gauze pads.

A longitudinal incision was made into the uterus, the bag of waters protruded and was ruptured, child delivered carefully, laid on right side, cord ligated. The placenta, which was attached directly over and around the internal os, was carefully separated and the uterus contracted satisfactorily. The uterus was sutured with two rows of silk. Abdominal wound closed by tier suture. The wound healed by first intention and the patient was discharged entirely well, Feb. 21, 1904. The baby is well and healthy.

What determined Dr. Bricker and myself to do cesarean section in preference to delivery by the natural way was: Previous deliveries by forceps, all of which were difficult, in addition to forced dilatation, version and perhaps forceps again; the risk to the child's life; danger to the mother, both from hemorrhage and injury to maternal parts; and in favor of delivery by abdominal section, the much less risk to the mother and being practically certain of saving the child, labor being but a few days of full term.

The results of cesarean section for placenta previa, so far as hitherto reported, are not very encouraging. They show a considerably increased mortality for the mother, and a not materially decreased death-rate for the fetus, as compared with those of the older methods. It has been possible to collect in all 25 cases where this method of treatment has been employed, in one of which, however, the results have not been determined (Storer's case, No. 22). Of the remaining 24 cases, 19 mothers and 8 children recovered, a mortality, respectively, of 20.8 and 66.6 per cent., including as a recovery the child in Tait's case, it having lived for one month and dying then from bronchitis. If we exclude the cases (Nos. 2, 14, 17, 19, 20, 21, 25) where the operation was undertaken before the fetus was viable, and those where it is known to have been dead before operation was commenced, the fetal mortality falls to 50 per cent., showing that in reality cesarean section will save more viable fetuses than can be saved by delivery *per vias naturales;* whereas, for the mother, the mortality in these cases is only 18.75 per cent., as against 20.8 per cent. in the whole series, and 28.5 per cent. where the operation was done before the fetus was viable or when it was already dead, showing that the earlier stage of pregnancy is more unfavorable for the mother.

If we now consider only those cases (Nos. 1, 3, 4, 5, 6, 7, 8, 9, 10, 11, 13, 14, 16, 18, 23, 24), sixteen in number, where delivery by cesarean section was a method of choice, not of necessity, as in the remaining cases (Nos. 2, 12, 15, 17, 19, 20, 21, 25), the fetal mortality is 56.2 per cent., and that for the mother 18.75 per cent., as against 87.5 per cent., fetal, and 25 per cent. maternal, where delivery by natural method was impossible. But in this last series—where cesarean section was imperative—of seven fetuses so delivered, no less than six were already dead or not viable, only one in the series recovering, thus making the improved fetal mortality 50 per cent.

In view, therefore, of these figures, it is evident that cesarean section is not a method to be unreservedly recommended in placenta previa, but that it should be confined, where a choice between it and obstetric delivery is possible, to those patients whose cervix is with difficulty dilatable, whose birth canal is rather contracted, where immediate extraction of the fetus is necessary, and where further hemorrhage would almost certainly kill either mother or child, or both.

CASES OF CESAREAN SECTION FOR PLACENTA PREVIA

1. Bernays: The Journal A. M. A., May 12, 1894. For placenta previa. Mother recovered. Child died in ten hours.

2. Bossi: See De Paoli: La Rassegna d'Ostetricia e Ginecologia, 1899, viii, No. 3, p. 155; quoted by Mattoli: Archivio Italiano di Ginecologia, 1899, ii, 309. For rupture of uterus with placenta previa. Mother died in twelve hours. Fetus dead when extracted.

3. Braun-Fernwald: Archiv. f. Gyn., 1899, lix, No. 2, p. 320. Porro, for placenta previa with uterine myomata. Mother recovered. Child died in three days.

4. Braun-Fernwald: Ibid. Porro, for sepsis with placenta previa. Mother recovered. Child died of atelectasis pulmonum.

5. Conroy: Bost. Med. and Surg. Jour., 1902, cxlvi, 634. For placenta previa. Mother recovered. Child dead when extracted.

---

[5] Among those who favor cesarean section in these cases are the following: Ford (Amer. Gynecol. Jour., 1892, ii, 525), Dudley (N. Y. Med. Jour., 1900, ii, 754), Boyd (Proc. Phila. Co. Med. Soc., 1901, iii, 117), and Donoghue (The Journal A. M. A., 1902, ii, 620); while articles opposing this method have been written by Ehrenfest (Amer. Med., 1902, i, 64), Schauta (Interstate Med. Jour., St. Louis, 1902, ix, 177), Murray (Amer. Med., 1902, i, 945), De Paoli (Archiv f. Gyn., 1903, ix, 15), and Higgins (Boston Med. and Surg. Jour., 1902, i, 6).

6. Covington: Cincinnati Lancet-Clinic, 1901, i, 558. For placenta previa. Mother recovered. Child recovered.

7. Deaver: (Case here reported.) For placenta previa. Mother recovered. Child recovered.

8. Donoghue: Bost. Med. and Surg. Jour., 1900, ii, 571. For placenta previa. Mother recovered. Child recovered.

10. Gillette: Ibid., 1901, ii, 9. Porro, for placenta previa. Mother recovered. Child recovered.

11. Hare: Ibid., 1901, i, 151. For placenta previa. Mother died in eleven hours. Child died in thirteen days of inanition.

12. Hopkinson: Amer. Med., 1902, i, 140. For contracted pelvis, with lateral placenta previa. Mother recovered. Child recovered.

13. Hypes and Hulbert: See Bernays, loc. cit. For placenta previa. Mother died. Child died.

14. Lanphear: Amer. Jour. of Surg. and Gyn., 1901, xiv, 132. Porro, at end of fourth month for infected placenta previa. Mother recovered. Fetus not viable.

15. Lodemann: Centralbl. f. Gyn., 1893, xvii, 564. For placenta previa with osteomalacic pelvis. Mother recovered. Child died.

16. MacCalla: Medical Sentinel, 1900, viii, 55. Porro, for placenta previa. Mother recovered. Child lived one week.

17. Mattoli: Archivio Italiano di Ostet. e Gin., 1899, No. 4, p. 305. For placenta previa, with undilatable cervix. Mother recovered. Child dead before extraction.

18. Omboni: See Stradiotti: L'Arte Ostetrica, 1902, xvi, 258. For placenta previa. Mother recovered. Child living when extracted; no subsequent history.

19. Pasquali: Atti della Soc. Italian. d'Ostet. e Gin., 1895, ii, 299. For contracted pelvis with placenta previa. Mother recovered. Child not viable.

20. Pasquali: Ibid., loc cit. For contracted pelvis with placenta previa. Mother recovered. Child not viable.

21. Sligh: Amer. Jour. of Obstetrics, February, 1892. For carcinoma of cervix with placenta previa. Mother died day of operation. Child dead when extracted.

22. Storer: Quoted by Mattoli, loc. cit. Porro, for "grave hemorrhage in pregnancy." Stump of uterus treated extraperitoneally, according to the original procedure of Porro. No history of mother and child given.

23. Tait: Lancet, 1899, i, 364. Porro, for placenta previa. Mother recovered. Child died in one month of bronchitis.

24. Truesdale: Boston Med. and Surg. Jour., April, 1903. For placenta previa. Mother recovered. Child died.

25. Webster: Amer. Jour. of Obst., 1901, xliii, 158. For placenta previa, in a mother of 13 years of age. Mother recovered. Child dead (?) when extracted.

SURGICAL OBSERVATIONS IN THE PHILIPPINES.*

J. M. BANISTER, A.B., M.D.

Major and Surgeon, U. S. Army; Commanding Officer, First Reserve Hospital.

MANILA, P. I.

Having for the past twelve months been closely associated with the surgical work at the First Reserve Hospital in the City of Manila, it has occurred to me that it might be of interest to the members of the Manila Medical Society should the results of this year's experience in surgery be presented to them, covering, as it does, a wide range of surgical conditions. Moreover, I am induced to select the above as the title of my paper by reason of the erroneous views prevailing in certain quarters, both in this archipelago and in the United States, as to the results of surgical work in the Philippine Islands. I shall first give a tabulated list of the various operations performed by the surgeons on duty at the First Reserve Hospital since Jan. 1, 1903, and then adduce certain conclusions, which would seem justified by the results. The operations enumerated below were performed by First Lieutenants W. L. Keller, assistant surgeon, U. S. A., E. L. Ruffner, assistant surgeon, U. S. A., Capt. H. R. Stiles, assistant surgeon, U. S. A., and myself. In the general list of operations the names of the responsible operators are given:

Operations.	Cases.	Operators.	Died.
Bassini operation for the radical cure of inguinal hernia.	59	Keller 22, Ruffner 4, Banister 33.	0
Radical cure for ventral hernia..	3	Banister	1
Operation for appendicitis......	30	Keller 12, Ruffner 1, Banister 17.	1
Laparotomy for perforating gunshot wounds of the abdomen.	3	Banister	2
Laparotomy for sarcoma of small intestine—extensive.	1	Keller	1
Laparotomy for rupture of intestine from blow on abdomen.	1	Keller	1
Laparotomy for acute intestinal obstruction	1	Keller	1
Laparotomy-exploratory	3	Banister	0
Radical operation for varicocele suprapubic incision.	49	Keller 31, Ruffner 10, Banister 8.	0
Large abscess, mammary region—incision and drainage.	1	Keller	0
Large lumbar abscess—incision and drainage.	1	Keller	0
Large abscess abdominal wall—deep incision and drainage.	3	Ruffner 2, Banister 1.	0
Abscess of liver. Operation for..	7	Keller 4, Banister 3.	2
Abscess—ischiorectal	1	Ruffner	0
Sebaceous cyst of back—large excision.	1	Keller	0
Sebaceous cyst of arm—large, extending beneath biceps muscle, excision.	1	Ruffner	0
Lipoma of forearm. Excision...	1	Ruffner	0
Large cyst of neck, deep. Excision.	1	Keller	0

GENERAL ANALYSIS.

In this list of 428 operations, such so-called operations as the opening of small abscesses, the removal of ingrowing toe nails and other surgical measures of similar slight importance have been carefully eliminated, although frequently included in the statistical tables of many hospitals. In scanning the list it can readily be seen that, of the 428 operations recorded, 145 may justly be ranked as capital. In this list may be noted 59 operations for the radical cure of inguinal hernia; 3 for ventral hernia; 30 for appendicitis; 9 other laparotomies, 3 being for perforating gunshot wounds of the abdomen; 7 operations for abscess of the liver, 5 being by the abdominal route; 3 external perineal urethrotomies, 1 with and 2 without a guide; 4 trephine operations for cranial injuries or their effects; 2 radical operations for suppurative mastoiditis; 1 excision of the anterior half of the tongue for malignant disease, and many other important operations. Of these operations 106 involved invasion of the peritoneal cavity.

In this list of capital operations there was a mortality of 12. One other patient in the general list died from septicemia, due to serious streptococcic infection of the deep tissues of the lip and face. The operation in this case was the use of the thermo-cautery, which can not be considered a capital operation, and hence has not been placed in such list. Of these 145 capital operations, 87 were performed by the writer, with a mortality of 6. Of the 6 fatal cases, four patients were moribund when placed on the operating table just after reaching the hospital, and a fifth, a patient suffering from a traumatic arteriovenous aneurism of the external carotid artery and internal jugular vein, which had become diffuse, was in momentary danger of death from hemorrhage, and the operation of ligation was attempted as affording a forlorn hope of saving life. In this connection, I shall state that since I have been connected with the First Reserve Hospital it has been the rule to operate on desperate cases, as soon as brought to the hospital, in order that such patients might be given their one chance of life. By following this rule I was able to save the life of one out of three patients brought to the hospital during the year suffering with perforating gunshot wounds of the abdomen. In this case the descending colon was wounded, and if the expectant plan had been followed this patient would, in my opinion, have died.

This man was brought before this society a few months ago, when a brief outline of his case was given. The sixth case of mortality, in my personal capital operations, resulted from acute tetanus, following what I considered, in every way, a most satisfactory operation for ventral hernia. A complete and exhaustive bacteriologic investigation as to the source of the infection in this case was immediately instituted by my order, the laboratory work being performed by Assistant Surgeon H. M. Smith, the bacteriologist and pathologist of the hospital. Everything connected with our technic was discovered to be blameless. True cultures of tetanus bacilli were, however, obtained from the scrapings of the floor of the operating room, the tetanus spores having presumably gained access to the wound by means of dust blown in from the street about forty yards in front of the hospital. It must be understood that the tiled floor of the operating room had been habitually subjected to scrubbing with a strong solution of carbolic acid.

Anaërobic cultures obtained from the floor of the operating room, as mentioned, produced tetanus when injected into rats. Since the occurrence of this lamentable accident the windows of the operating room on the side facing the street have been kept closed, or covered with wet sheets, during operations. Furthermore, as additional precautions against the possibility of harboring or of introducing tetanus spores by means of dust the operating room is scrubbed out with strong solution of carbolic acid just before each operation, clean sheets are spread around the operating table, and no one is permitted to enter the operating room in shoes which have been worn outside. Slippers, which have never been used outside of the operating rooms, are kept in the surgeon's dressing room for the use of the surgeon and assistants or others entering the operating room. We have had no other trouble on the score of infection from tetanus.

Thus in the six cases of mortality in my 87 capital operations, five were from their very nature doomed in advance, and were subjected to operation simply as giving the unfortunate patients a last chance. The tetanus case is the only one in which the fatal result can, in any way, be attributed to the operation. The most of the remaining 58 capital operations were performed by First Lieutenant W. L. Keller, assistant surgeon, U. S. Army, and the remainder by his successor, First Lieutenant E. L. Ruffner, assistant surgeon, U. S. Army. In all important operations performed by my assistants, I almost invariably act as first assistant, and hence am perfectly familiar with all surgical results in the hospital. In this series of 58 capital operations performed by my surgical assistants, six deaths resulted, the fatal cases being as follows: (1) One case of malignant appendicitis in an officer, whose family opposed operation until a successful result was impossible in consequence of gangrene of the intestine. This operation was performed by Dr. Keller just prior to my arrival at the First Reserve Hospital. (2) One case of sarcoma of the small intestine so extensive as to preclude any attempt at removal, so that the operation simply amounted to a laparotomy with inspection of the growth. (3) A case of septic peritonitis due to a traumatic rupture of the small intestine, in which a laparotomy was performed in accordance with our established rule. (4) One case of acute intestinal obstruction from bands of adhesions, the intestine being extensively gangrenous and the case hopeless, the operation consisting in a laparotomy with relief of the constriction. (5) Two cases of hepatic abscess with multiple and extensive abscesses throughout the liver.

As can be seen these six cases, as five of my six, were doomed from the first, and were hopeless when subjected to operation in accordance with our rule to let no man die without making an effort to save him. In considering this mortality rate of twelve deaths in 145 capital operations, our percentage would be, considering the results in hopeless cases as being chargeable to the operation, 8.2 per cent. Taking the whole number of operations given in the general list, amounting to 428, the mortality of 13 would give our death rate as 3.03 per cent.

THE POSSIBILITY OF ASEPSIS.

Before coming to the Philippines I had heard a great deal of talk in the United States about the poor surgical results to be expected in these islands owing to climatic conditions, lack of proper sanitation, and many other factors, under whose saturnine influences the various pathogenic bacteria, most to be dreaded in surgery, would flourish and infect, infect and flourish, at their own sweet wills, while the poor surgeon could only stand by helplessly wringing his impotent hands, and bemoaning his fate at being thus compelled to practice his art in such fatal surroundings. In fact, such statements have not solely emanated from the United States, for a good deal of comment of the same tenor has been and is still heard in the Philippines. I feel that, from the number of cases of surgery which I have had an opportunity of observing in these islands, I am to some degree entitled to express an opinion on the subject, and I desire to say, without the slightest reservation, that, with proper aseptic and operative technic, just as good results may be expected to follow operative work here as in any country under the sun. When septic infection occurs in operation wounds in the Philippines, the fault must be looked for in the technic, not in the climate. Aseptic surgery in the Philippines may be expected to have the same results as would follow the same technic in New York, Ohio, Kansas or California. This is absolutely true for pyogenic infection. The great prevalence of tetanus spores in the soil of the Philippines adds a possible element of danger, which would not be encountered in many portions of the United States. As proved by my fatal case of tetanus, spore bearing dust must be guarded against in our operative work in this part of the world.

As a proof of the correctness of the views just expressed, I shall state that at the First Reserve Hospital we have secured an almost continuous series of aseptic results. In our series of 59 hernia operations, during the past twelve months, we discovered only one small superficial stitch abscess, which was not worthy of the name of "abscess," but which was recorded as such, as we perferred to err on the safe side. In every one of our interval operations on account of former appendicitis, or of our appendicectomies performed during the acute stage before infection outside of the appendix had occurred, has first union resulted. The same can be said of all of our other clean cases, with three slight exceptions, and the only instances of pyogenic infection occurring in such cases at this hospital, since I have been connected with it, have been the following: (1) The small stitch abscess which occurred in the subcutaneous tissue in the hernia case, previously referred to. (2) Suppuration ensued in one operation performed on the knee joint on account of a serious injury, which had broken the patella into many fragments. (3) In an operation for the repair of the fascia lata, in the case of hernia of the adductor longus muscle, a slight superficial infection resulted. This was of no importance whatever, and occurred as a result of the slipping of the dressing and a consequent uncovering of the wound, while the patient was in bed soon after the operation. It seems to me that such aseptic results, which have been obtained in an old Spanish hospital building in the much-criticised Philippines, and which are not surpassed, as far as I have been able to learn, in any hospital in more favored climes, should forever set at rest all doubt regarding the proposition, which I have advanced, that clean results may be expected to follow clean methods here as constantly as in other portions of the world. So much for the dangers of septic infection.

RECUPERATION IN THE PHILIPPINES.

As far as recovery after operations is concerned, I desire to advance the broad proposition that surgical cases, subjected to operation, recuperate here in a most satisfactory manner. After serious operations there is here the usual slight aseptic rise of temperature, just as is the case in the United States or Europe, with a speedy fall to the normal. This applies especially to clean cases, but in pus cases, after thorough drainage has been established, we find the patients progressing toward recovery in the same manner that we have been accustomed to see in our best equipped and regulated hospitals at home. After such operations as those for the radical cure of hernia, for appendicitis or surgical measures of similar severity, our soldiers are able to return to their regiments in as reasonable a period of time as I have been accustomed to see in the United States in the same class of cases. As far as the permanency of the cure in such cases is concerned, I desire to state that I have not heard of a single case of relapse in the 59 cases of hernia subjected to operation since I have been connected with this hospital, and I only know of two cases of ventral hernia resulting from all the rest of our abdominal operations performed during the past year and resulting in recovery. These two cases of ventral hernia occurred in patients who had had large appendiceal abscesses, which had required drainage for a considerable time. Thus out of 106 cases, in which the peritoneal cavity has been invaded by the surgeons of the First Reserve Hospital during the past twelve months, only two cases of post-operative ventral hernia have resulted.

RESULTS IN APPENDICITIS.

In a paper entitled "The Modern Radical Operation for the Cure of Non-Strangulated Inguinal Hernia," read before this society some months since, I expressed fully my views on the subject of hernia, and the views then expressed relative to the value of this operation have simply been strengthened from further experience with it in the tropics.

With reference to appendicitis in the Philippines, a few notes may not be out of place. In the first place, apendicitis here is the same disease, with all its different forms and types and complications, that we have been accustomed to encounter at home, and in my Philippine experience I have not been able to observe any relation whatever between climatic conditions and the special type of the disease present in any case. For a time, after assuming my duties at the First Reserve Hospital, I was of the opinion that this disease was more prevalent here than in the United States, but on further observation, I have changed my views on this point. When it is borne in mind that the hospital mentioned is the large general military hospital for the Philippine archipelago, and that in it are treated almost all of the serious surgical cases that can be transported to this point from the entire military personnel in the islands, including officers, enlisted men, American employes of the various departments of the service, native scouts and native employes of the military establishment, it can well be appreciated that our series of 30 operations for appendicitis in the past twelve months is an infinitesimal ratio. Another point of interest in this connection is this, that all of our appendicitis patients, since I have been at this hospital, have been of the white race, and that no record can be discovered here of any native having been treated for this disease in past years.

In our list of 30 operations for appendicitis in the past twelve months, as before stated, there was one death from a most malignant attack with gangrene of the cecum, operation not having been permitted until too late. This occurred just before my arrival at the hospital, and consequently I did not personally observe the case, but since the patient was under the professional charge of First Lieutenant W. L. Keller, assistant surgeon, U. S. Army, one of the most careful, judicious and accomplished surgeons of my acquaintance, I feel sure that he received every attention, and that he was a doomed man before he was placed on the operating table. The 29 patients remaining recovered, although the great majority of them were in very serious conditions. This year's record for this dangerous disease, which shows that recovery resulted in every case in which operation was permitted when the surgeon had so advised, does not offer a very strong argument in favor of the deadly effects of this climate in serious surgical work. I have no more fears concerning the outcome of an operation for appendicitis here than I would have in a similar case in the United States, neither am I afraid to operate early in an acute attack. There is no more demand for delay in operation here than would be the case in any other country, and I must confess that all of my surgical tendencies are opposed to delay in appendicitis work. I consider appendicitis a strictly surgical condition, and see no logical reason for waiting for the formation of abscess, perforation with probable septic peritonitis, or gangrene of the appendix and cecum, with all that such conditions imply.

If our acute appendicitis cases do not speedily improve when admitted to the First Reserve Hospital as shown by a rapid decline of leucocytosis, and by an amelioration of general and local symptoms, the patient is subjected to operation without delay. This has always been my practice, and that it is not opposed to reason is evidenced by the fact that, in my limited experience as an operator for appendicitis, no case of mortality has resulted. I make this statement in no spirit of egotism, but as a simple declaration of fact.

A few days ago I removed an appendix during the early period of an acute attack of apendicitis, when, from the symptoms, it had become evident that the disease was steadily progressing. This appendix contained a number of fig seed, these little bodies being distributed from the apex along the entire length of the interior of the appendix. This is the first case in my own experience, in which the appendix was found to contain fruit seed of any kind. The advantage of the early operation in such a case can be readily appreciated.

In concluding these desultory remarks on appendicitis in these islands, I shall state that we take no account of the climate in our treatment of such cases at the First Reserve Hospital, but are guided here by the same considerations which would influence us in the United States, and confidently expect the same results that would obtain there.

HEPATIC ABSCESS.

Abscess of the liver is a great bugbear in the tropics, but at the First Reserve Hospital, with a very wide area of territory from which to draw our clinical material, we have only had six patients with this disease during the past twelve months. One patient was operated on twice; once under general anesthesia by aspiration in the attempt to locate the abscess, and the last time by the abdominal route with evacuation of the abscess. In this case aspiration utterly failed to show the presence of pus, although this procedure was most carefully performed through several different punctures. These six patients were subjected to operation: one by the thoracic route, after resection of a rib, and the remaining five by the abdominal route. A previous history of amebic dysentery was the rule in these cases. There were two deaths in these six cases, in both of which the abscesses were multiple and very extensive. In the four patients who recovered, the abscesses were single, though, as a rule, large. From my own observation, and from conversation with other surgeons relative to liver abscess in this climate, I have formed the opinion that with a patient not moribund, and with a single abscess to contend with, a careful operation, either by the thoracic or abdominal route, will afford a very favorable prognosis. In cases of multiple abscesses the prognosis is very gloomy, as patients so affected almost invariably die. Of these six patients suffering from hepatic abscess, two were natives. I am especially interested in the fact that two natives were victims of the disease, as I remember reading a short while since in one of the medical journals, published in the United States, that liver abscess was unknown among the natives of the Philippine Islands.

BONE SURGERY.

Bone surgery in the Philippines has results that can not be excelled in any part of the world, provided, of course, that a thorough aseptic technic is employed. In a case of comminuted fracture of the clavicle of a degree to render proper apposition impossible with the usual methods of treatment, or in a suspected fracture of the cranium with symptoms of cerebral compression, or in necrosis involving the bone in any portion of the body, I would not be induced to delay operation by any fears on the score of the climate. The results in such cases have been eminently satisfactory to the surgeons at the First Reserve Hospital. In cases of comminuted fracture of the clavicle of such a character as to preclude the possibility of recovery with useful shoulder under other treatment, I would operate at once, thoroughly exposing the fractured bone at the seat of the injury, placing the fragments in correct apposition under the guidance of vision, and holding them in such position by means of proper wiring with silver wire. I would do this in hope of securing a perfect result in spite of the climate, and all its supposed deleterious influences on surgical work. In fact, during the past year we have done this very thing in two serious cases of this type which were brought to the First Reserve Hospital. Dr. Keller was the responsible operator in one case and I in the other. Both patients made perfect recoveries with useful shoulders, my patient performing now his accustomed work as wheelwright in the employ of the quartermaster department in Manila. As a proof of how successful the operation of wiring the patella may be in this climate, I present for examination this evening a patient, on whom I performed this operation a short while since.

As noted in the preceding pages, I was called on to treat at the First Reserve Hospital, during the past year, three cases of perforating gunshot wound of the abdomen. In each of the three I performed a laparotomy after admission to the hospital. One patient, a soldier who had been accidentally shot by a comrade with a Krag rifle, was brought to the hospital moribund in about thirty minutes after the reception of the wound. The common and external and internal iliac veins of the right side were found to have been torn to pieces at their junction, and death occurred on the table as the result of the excessive hemorrhage so caused.

A second laparotomy for gunshot wound of the abdomen was performed in the case of a Filipino scout, who had been shot by ladrones early one morning about 3 o'clock, and who was brought to the hospital after 11 o'clock on the following night. At the operation I discovered that the small intestine had been so severely lacerated at one spot that it would be necessary to resect the bowel, and make an end-to-end anastomosis. This was done, the anastomosis being made with the Murphy button. The patient lived four days, and at the necropsy it was found that the intestine was gangrenous for about a foot on each side of the union. The anastomosis, however, had not yielded. This man might have been saved if he had reached the hospital soon after his injury was received.

The third case was brought to the operating room within two hours after being wounded with a 38-caliber revolver at close range. I opened the abdomen, found the wound in the bowel, which was the descending colon in this case, repaired the wound, cleaned out the peritoneal cavity, closed the abdomen, using a small cigarette drain of gauze covered with rubber tissue, and the patient made a rapid and uneventful recovery. The first two cases I considered to have been necessarily fatal cases, and the fatal issue in no wise attributable to the operation, while the third case, which made such a satisfactory recovery, would certainly have died without operation.

CONCLUSIONS.

It is not necessary to discuss all of the interesting cases or types of cases in the list of operations which I have given. Those cases with results, which I have specially brought forward, when considered in conjunction with the tabulated list, will, I trust, furnish sufficient evidence of the propriety of the views which I have expressed in the preceding pages on the subject of surgery in the Philippine Islands, which views I beg leave to present, in conclusion, in the form of the following propositions:

1. Aseptic results will just as surely follow aseptic methods in the Philippines as in the United States or in Europe.
2. Should septic infection occur in any clean case subjected to operation in the Philippines, blame the technic, not the climate.
3. Successful attainment of the object, for which operation has been undertaken, will follow careful and skillful surgery in the Philippines with the same regularity that we have been accustomed to observe in such work at home.
4. Convalescence after surgical operations in the Philippines is rapid and satisfactory, when such operations have been carefully and skillfully performed.
5. The danger of mortality after a skillfully performed surgical operation, in which all the details of a rigid aseptic technic have been carried out, is not increased by the influences of the climate of the Philippines unless the patient is, at the same time, the victim of some other serious disease.

A CLINICAL STUDY OF THE BACILLUS DYSENTERIÆ IN BOSTON AND VICINITY.*

ROBERT W. HASTINGS, A.M., M.D.
Resident Physician on the Boston Floating Hospital.
BOSTON.

The assignment of Arthur I. Kendall by the Rockefeller Institute for Medical Research to work with us on the Boston Floating Hospital during the season of 1903, has enabled us to make a few scientific and clinical observations which may be of some value to the medical profession, and hence are reported. Not less important than the expert work of Kendall was the hearty co-operation of the Boston Board of Health, the facilities of whose large laboratory were placed at his disposal.

The *Bacillus dysenteriæ* was discovered by a Japanese physician named Shiga in 1898. It has many characteristics in common with the bacillus of typhoid fever, thus justifying bacteriologically the position that we have taken in favor of the use of the most careful "typhoid precautions" in these cases. It differs from the typhoid bacillus in various ways—for example, its motility and its action on mannite.

Cultures may be fed to animals without any outward effect, but when injected under the skin or into a vein a powerful toxin is developed. Flexner found the same bacillus in the Philippine Islands, and he and his assistants have since searched for and found it in many places in the United States.

This study has developed the existence of a group of these bacilli, differing from each other in some ways, but markedly similar in others. Temporarily these are divided into two classes styled "Shiga" and "Harris," respectively. Drying and sunlight quickly make them powerless, and the common disinfectant methods of typhoid fever are equally efficient, for they are found in the dejecta of patients. Moreover, agglutination tests similar to those employed in typhoid fever are successful. A drop or two of blood from a patient, diluted

---

* Read before the Norfolk District Medical Society.

100 times, produces clumping of Shiga bacilli obtained from pure cultures within from two to four hours. Furthermore, it has been proved that a serum may be produced from horses in precisely the same way as diphtheria antitoxin is produced, which has marked powers to render guinea-pigs immune, and which it is, therefore, hoped may be produced powerful enough to check the ravages of the germs in the human system.

The Japanese use such a serum for bacterial dysentery, and have reduced the former mortality of over 50 per cent. to an average of only 10 per cent. or 15 per cent. The Rockefeller Institute for Medical Research, of which Dr. Simon Flexner, mentioned above, is the medical director, has set itself the task of determining whether this germ, so positively identified in the East, so readily detected by agglutination tests, and so amenable to serum treatment, is the same germ which every summer carries off thousands of infants under 2 years old. In this investigation it was our privilege to be one station, similar work being carried on by other assistants in Baltimore, Philadelphia and New York.

If further work shall make it probable that the *Bacillus dysenteriæ* (Shiga) is the cause of a large portion of our cases of summer diarrhea, a method of diagnosis analogous to the Widal test will be available to the diagnostician. Moreover, the identification of the cause in this case means the immediate use of a cure. Once firmly proved, therefore, a work in no sense secondary to the introduction of the antitoxin treatment of diphtheria will have been accomplished. Hence there was marked enthusiasm in this portion of our work this last summer.

Thirty-five cases were carefully studied, and in 28 the *Bacillus dysenteriæ* was demonstrated. Twenty-three were of the Harris variety, 3 of the Shiga, and 2 showed both varieties. Of the 5 cases pronounced negative, one, No. 20, seems like a case in which nature very vigorously attempted to rid the rectum of the invading germs, which were probably derived from a younger sister very ill with ileocolitis. The great amount of mucus concealed the germ cause. Case 26 was not a very severe one, and no clinical explanation for the failure to find the bacillus is available. Case 32 was very unsatisfactory clinically as well as bacteriologically, and much surprised her visiting physician by the suddenness of her death. Cases 33 and 35 were evidently meningitis. The local pathologic lesions of what we have termed clinically ileocolitis have in each case proven to be "much thickened intestinal walls, with prominent, injected, sometimes ulcerated, follicles and a coating of thick glairy mucus." It is possible to study these cases in very many ways. It is hoped that the grouping adopted may prove of interest and value. It is practically identical with that used in the report to the Rockefeller Institute.

PREVIOUS ATTACKS OF DIARRHEA.

The histories obtained were in many instances unreliable, owing to the lack of knowledge displayed by parents in regard to previous attacks of diarrhea. In only four cases was there a history of previous enteric disturbance. Of these, Cases 11, 12 and 15 gave histories of previous attacks, during the earlier summer. One case (18) had two previous attacks, one of ileocolitis the preceding year, and a second earlier in the season of 1903.

CHARACTER OF FOOD AT TIME OF ATTACK.

Of the cases proving positive, 2 were breast-fed exclusively (5 and 14); 5 cases were fed on condensed milk alone; ordinary table diet to 3; cow's milk diluted variously with water or cereal infusions, but without regard to accurate modification had been given to 7; proprietary food alone was given to 3; in combination with milk to 4; a restricted diet of bread, beef juice and milk had been given to 3; in 1 case the diet is not stated.

DISCOVERABLE CAUSE OF ATTACK.

As to a discoverable cause, no one cause can be assigned to any case except Case 14. In most of the cases the food of the children lacked even ordinary care in its method of preparation. The milk was the ordinary milk of the household, kept in many instances in the usual unhygienic surroundings. In no case had the food been sterilized before being given to the child. In one case, a breast-fed child, the onset seemed to be synchronous with the use of a breast pump.

LENGTH OF SYMPTOMS BEFORE OBSERVATION.

The average duration of symptoms before coming under observation was seven days. The longest period was six weeks, a diarrhea of the fermental type. The shortest period was one day, a fatal case of cholera infantum. In one case there is no history of duration given.

PERIOD UNDER OBSERVATION.

The average period of observation was eighteen and three-fourths days. The shortest periods were in three cases, each of which died on the day of entrance. The longest period of observation was sixty-three days (Case 27). The average age was 10 months, the youngest patient being 3 months and the oldest 4 years.

CHARACTER OF ATTACK.

Of the positive cases, 3 are noted as mild, 5 as of moderate severity and 20 as severe. Of the mild cases, 2 were discharged well, and 1, when entirely over the enteric trouble, finally developed symptoms of what was probably central pneumonia, from which she finally recovered. Of the moderately severe cases, 1 was discharged well, 2 were relieved; 1 complicated by tubercular adenitis and chronic otitis media was discharged unrelieved, and the remaining case developed lobar pneumonia, from which she died. Of the severe cases, there were 13 deaths, 5 recoveries and 2 unrelieved, both of the latter cases dying outside the hospital.

TYPE OF ORGANISM.

Of the 28 cases, 23 were infected by the Harris type of organism, 3 with the Shiga, and in 2 cases both were isolated. The small number of cases presenting the *Bacillus dysenteriæ* (Shiga) precludes much comparison. The 3 cases presented no marked difference from the rest of the cases. The 2 cases of double infection were both severe, but had no difference in symptoms from the other cases. Of these 2 cases, 1 died and 1 recovered. Of 3 cases of Shiga infection, 1 was moderate and recovered, 1 moderate and relieved, and 1 severe case died.

BREAST-FEEDING.

There were but two cases breast-fed at the time of entrance.

Case 5.—A boy, 11 months old, well developed and nourished, entered with a temperature of 104 F., delirious, furred tongue, mild diarrhea, 4 to 6 dejections per diem, green with mucus. On the heel of the left foot was a bleb surrounded by an erysipelatous process. Numerous abscesses of the leg developed later, were opened and evacuated. The *Staphylococcus pyogenes aureus* was isolated. There was final recovery.

As the enteric disturbance was never very annoying, and as a prolonged search of several hundred colonies revealed only one colony of the *Bacillus dysenteriæ* (Harris), the relationship as a causative factor is problematic.

Case 14 is interesting as to etiology. The mother stated that on account of a cracked nipple she had begun a week previously to the onset to use a breast pump, of which little care had been taken.

Case 14.—A boy, 10 months old, fairly well developed and nourished, somewhat hydrocephalic, slight rosary, no teeth, anterior fontanelle 1¾ x 1 in. Dejecta 8 to 10 a day, green mucus and occasionally streaked with blood, considerable tenesmus. Temperature 99 to 101 F. Child refused to nurse, dropper feeding was resisted so as to exhaust child, esophageal feeding was regurgitated. At times nasal feeding was retained. Vomiting was persistent, and toward the end vomitus contained blood in pinhead size clots. Day of death had two convulsions.

---

* No discoverable cause of the attack save in Case 14, where an unclean breast pump had been used. † Autopsy showed ulcerative colitis.

FATAL CASES.

The histories of the fatal cases were as follows:

Case 2.—Boy, age 7 months; well developed and nourished, slightly anemic, tongue dry with white coat, collapsed and drowsy. Temperature 104 F. Very weak. Persistent vomiting. No tenesmus. Dejecta 6 to 9 a day, green mucus and blood. Died five days after entrance. Treatment: Stimulant and serum, Harris (132 F.) 10 c.c. on three days. No change after first day, when child seemed brighter. There was no change in character of pulse. The dejecta remained unchanged, but dropped in number. The fifth day temperature rose to 105.4 F., and child died.

Case 3.—Boy, age 2 months, poorly developed and nourished. Slight rosary. *Few râles in back. Heart* action weak, peripheral circulation sluggish. Child restless. Occasional vomiting. Dejecta 6 to 10 a day, green with mucus. Some tenesmus. Treatment: Stimulant and serum. Child lived 9 days. Serum given six times, 10 c.c. on consecutive days; temperature dropped from 104.8 to 96 F. Improved slightly for two days, then failed rapidly. Dejecta unchanged. Child practically moribund on entrance.

Case 6.—Girl, age 5 months; fairly well developed and nourished; pale. Temperature 102 to 105.6 F. Pulse weak, somewhat restless at times. Child was prostrated on entrance, severe tenesmus, marked vomiting. Lived 48 hours. Dejecta 12, green fluid with mucus. Treatment: Stimulant. No serum.

Case 8.—Girl, colored, age 3 months; well developed and nourished; tongue coated, fontanelle depressed; pulse weak, intermittent; extremities and skin cold and clammy; stuporous; temperature 101.5 F. Dejecta very *thin, faint* green tinge, four *in* number. Face pinched. Died a few hours after entrance. Had two convulsions. First limited to right arm. Later general. Duration of one day; vomiting and twenty dejections. Autopsy after 16 hours: Thymus to fourth rib. Pericardium about 10 c.c. fluid. Slight hypostatic congestion of both lungs. Mucosa of colon slightly injected. Cultures made from scrapings of mucosa.

Case 13.—Girl, age 20 months; well developed and nourished. Prostrated, extremities cold and cyanosed, tenesmus. Comatose. Circulation fair. Temperature 104.8 F. Lived two hours. Moribund *on entrance.* Treatment: Serum 20 c.c. No response to saline infusion or stimulation. Autopsy refused.

Case 16.—Girl, age 7 months; well developed *and nourished.* Prostrated, heart sounds weak. Skin inelastic. Restless. Temperature 101 to 104 F. Dejecta 6 to 9, green with mucus and blood. Treatment: Stimulation of no avail. No serum.

Case 19.—Boy, age 13 months; well developed and nourished. Physical *examination negative.* Drowsy. Slight tenesmus. Dejecta 5 to 10, brown with mucus. Mild constant vomiting. Temperature 100 to 102.5 F. Lived 6 days. Twenty c.c. serum given once without effect. Stimulation no effect. Died with meningeal symptoms, unequal *pupils,* Kernig's *sign,* retracted head, arms flexed and somewhat spastic.

Case 23.—Girl, age 18 months; well developed and nourished. Prostrated. Temperature 104.8 F. Tenesmus. Dejecta 4, yellow green with mucus. Lived 28 hours after entrance. Treatment: Stimulation. Autopsy shows a "colon thickened, scarcely pliable. Bleb-like lesions resembling herpes of skin." Probably early stage of follicular ileocolitis.

Case 25.—Boy, age 3 years; poorly developed and nourished. Physical examinations negative. Drowsy. Dejecta 2 to 9, green with mucus, and blood streaks. Treatment: stimulation and saline infusion; no serum. Case *moribund on entrance.*

Case 27.—Girl, colored, age 4 months; fairly well nourished. Rosary. Dejecta 5 to 8 a day; greenish-yellow, with mucus. Dejections in several instances consisted of purulent material, almost wholly small, mononuclear lymphocytes. Suffered considerably from distension. The enteric trouble had ceased when signs of pneumonia appeared and failed to resolve. Postmortem examination showed suppurative pericarditis, unresolved pneumonia and a small sacculated empyema. No serum had been used. Duration 55 days.

Case 29.—Boy, age 5 months; well developed and nourished. Some tenesmus. Restless. Dejecta 2 to 4, greenish-yellow, with mucus; gradually fell into stuporous condition. Lived 12 days. No serum used.

Case 30.—Girl, age 3 months; well developed and nourished. Prostrated on entrance. Somewhat restless. Signs of pneumonia, in right base posteriorly. Autopsy showed bronchopneumonia. Gastroenteric tract normal. Serum 2 doses, 20 c.c. each without effect.

Case 9.—Boy, 6 *months of age,* well *developed and nourished;* slightly anemic. In poor condition on entrance, pulse weak, 134. Temperature 103.5 F. Dejecta 8 a day, green with mucus. Under treatment 8 days. Serum given twice, 10 c.c. No apparent effect. Discharged unrelieved, died later.

Case 15.—Boy, 6 months of age; well developed and nourished; in good condition. Restless. Marked tenesmus. Excellent general condition. Dejecta 6 to 9 a day, much mucus and pure blood. In this case there were two distinct recrudescences during each of which crops of the *B. dysenteriæ* (Harris) could be easily isolated in 24 hours. Serum was given for 15 days, 10 c.c., *twice a day for one week.* The course of the case was down hill. The child developed purpura. Discharged after being under observation for six weeks. Child died a week later at the Children's Hospital. Autopsy showed a much thickened but healed colon.

SERUM TREATMENT.

Of the 16 who died, 5 received serum in addition to all other treatment; of the 11 discharged well, 7 had serum; of the 4 relieved, 2 had serum; of the 4 unrelieved, all had serum before leaving us.

Of the 5 who died and who received serum, 1 received three doses of 10 c.c. each; 1 five doses of the same amount, and 3 each received one dose of 20 c.c.

Of those discharged unrelieved, 1 received two doses of 10 c.c., 1 three doses and 1 eight doses of the same amount, while the fourth had 20 c.c. at one dose.

Of the discharged well who had serum, 3 had two doses of 10 c.c., 1 three doses and 1 nine doses of the same amount, while 2 had the larger dose of 20 c.c.

One of the two discharged relieved had a single dose of 10 c.c. and the other had five doses of the same quantity.

One of the two who recovered following the single dose of 20 c.c. was 6 months old and the other 17 months old.

CONCLUSIONS AS TO SERUM TREATMENT.

Hence it does not seem that any positive conclusions can be drawn from our experience with the serum. We are confident that no harm was done. The form in which it was furnished was entirely satisfactory from a practical point of view, being, we believe, a duplicate of the way in which Mulford issues diphtheria antitoxin. If we can have a supply another year we shall be glad to try it further. We believe a stronger serum which will then be available may be more efficient.

In conclusion, I would acknowledge with thanks the assistance of the house staff, and especially of my senior house officer, Dr. John F. Fennessey, whose co-operation alone has made possible this report.

THE PANAMA CANAL AND ORAL HYGIENE.

EUGENE S. TALBOT, M.S., D.D.S., M.D., LL.D.
CHICAGO.

Among the diseases which will extensively prevail during the work on the Panama Canal is interstitial gingivitis.

In this disease the alveolar process and gums are involved, the teeth become sore and loose and finally sometimes drop out. Medically, so far as the gums and teeth are concerned, the disease is not unlike scurvy, The pathology and etiology at bottom are the same. It is caused by change of climate and food. Men going from a temperate to a hot or cold climate are quite prone to this disease. Soldiers in the Philippines, according to official report, are attacked by a disease of the gums—the teeth become sore and drop out. General Otis' (mail) report cites the case of Walter Fitzgerald, Company C, Twenty-eighth Infantry, formerly of the Montana Volunteers. This man of 23 years had been in the Philippines for a year and seven months. He was one of the first volunteers to reach Manila after Dewey's victory. Nineteen months in the tropics, subsisting on the rations of the Army, had resulted in the loss of nearly every tooth in his mouth. In a man of his age this was a rather severe attack.

The engineers and workmen on the Jungfrau (Switzerland) Railroad, after two or three weeks in the high altitude, suffer from symptoms similar to those observed in the Philippines. Food as well as climate has clearly much to do with the disease. The excretory organs do not adjust themselves to the new environment and auto-intoxication results. Intestinal fermentation, one of the great causes for this disease, also occurs. Indicanuria and allied states are symptoms of this disturbance. Vasomotor ataxia is frequent.

On examination of the officers and soldiers of two companies who had just returned from the Philippines, located at Fort Sheridan, Ill., I obtained the following data: Total number examined 127. Americans 98, Irish 12, Germans 9, English 3, Norwegians 1, South Americans 1, Danish 1, Russians 1, Cuban 1. The ages ranged from 21 to 52. By ages the following data were obtained: 21 years—8 had the disease, 22—5, 23—17, 24—12, 25—15, 26—9, 27—4, 28—8, 29—11, 30—5, 31—4, 32—7, 33—1, 34—2. 35—none, 36—1, 37—7, 38—1, 39—3, 40—none, 41—none, 42—1, 43—1, 44—1, 45—none, 46—1, 47—1, 48—none, 49—none, 50—1, 51—none, 52—1. Of the total 127, 18 were free from the disease; it was marked in 36, medium in 27, slight in 46. The percentage of those free was 14.1, marked 28.3, medium 21.2, slight 36.2 per cent.

It will be noted that the largest number of cases of the disease occurred between the ages of 21 and 30, a period of life at a constructive stage when the disease should not be present. The men over 40 were nearly all officers who took better care of their mouths. It must also be noted that these men lived most of the time in the open air. In the American Army mostly young men are enlisted. It is obvious that the effect of climate and food is very severe.

There is probably no part of the United States where this disease is so prevalent and so demonstrable as in the northwest. The sudden changes of temperature from extreme heat to cold and the passage from heated houses into the cold atmosphere, and vice versa, prevent adjustment of the excretory organs to unequal temperature, thus resulting in auto-intoxication.

The alveolar process (holding the teeth in position) is a double transitory and most sensitive structure of the body. After its development about the permanent teeth, it is only waiting for some irritant to cause a low form of inflammation in order to destroy the bone tissue. This is done by three forms of bone absorption, namely, halisteresis, Volkmann's perforating canal and lacunar or osteoclast absorption. The form of absorption most active in this disease is halisteresis. The bone is soon destroyed and the teeth loosen and drop out. It is not a painful process; the inflammation may exist for years and the patient be unmindful of its presence until the teeth loosen and are sore to touch.

The treatment indicated is both local and constitutional. The local treatment consists in the removal of the deposits about the roots of the teeth and saturation of the gum margins with iodin, or what is better still, with the following, which should be applied every other day:

℞.	Zinc iodid	15
	Water	10
	Iodin	25
	Glycerin	50

The gums should be massaged three times per day with a stiff brush. They should be made to bleed freely. This will remove the congestion and stimulate the gums and alveolar process to a healthy action.

Constitutional treatment consists in removing the cause. Men going from the north should be very careful of their diet. Food adapted to warm climates should be used. Meat diet should be regulated to the capacity of the individual and as soon as possible. Faulty metabolism must be corrected. Above all, the organs of elimination must be adjusted to the environment as soon as possible. Since the alveolar processes are transitory structures and more easily affected by disease than others, they and the gums are excellent early indices of grave constitutional complications.

Nutmeg Habitation.—F. B. Brubaker reports in the *Medical Summary* that a young woman of 16, by repeated tasting of nutmegs while doing household baking, acquired a habit for the narcotic. The symptoms were weak and rapid heart, profound anemia, general muscular weakness, dyspnea and emaciation.

ROUTINE METHOD OF DETECTING AND DIFFERENTIATING REDUCING AGENTS FOUND IN THE URINE.*

W. G. DOERN, M.D.
FORT MADISON, IOWA.

It is my purpose in this paper briefly to call attention to a few well-established facts, point out some of the fallacies of our principal tests and outline a reliable and simple course of procedure for the differentiation of the various reducing agents which may appear in the urine. Most of the tests ordinarily employed are good negative tests, but to accept a positive reaction without confirmation is a frequent source of error in diagnosis, as I shall point out.

While, as a rule, we are called on to determine the presence or absence of dextrose, occasionally it is very important to determine whether or not other carbohydrates, as well as some other compounds, are present in the urine. Without exact confirmatory tests, it is practically impossible to definitely determine the presence or absence of dextrose. It is a rule with many physicians to depend on one single test for sugar, and rarely is it considered necessary to employ confirmatory tests. That such methods are not reliable will be evident if we consider the fallacies of the various tests. Some of these fallacies have been pointed out but recently, while others have long been emphasized, but still a few of the principal tests have been accepted without further inquiry.

THE COPPER TEST.

Perhaps the most popular of all sugar tests is the old Trommer test, or some modification of it. The chemistry of all copper tests is practically the same. The reagent consists of a solution of cupric hydroxid or, if the solution be older and after heating, the cupric oxid. A positive reaction consists in the reduction of the cupric oxid to cuprous oxid, which manifests itself as a yellow or red precipitate. There are some objections to Trommer's test which make it less accurate and not so convenient to use as some other solutions.

1. It requires two separate solutions to be mixed when the reagent is needed.
2. If these solutions are not used in the proper proportion a precipitate will form.
3. A large quantity of urine is required, increasing the liability of error from the presence of uric acid, creatinin and the phosphates precipitated by the KOH.
4. The test is not delicate without boiling, and when boiled becomes oversensitive.

A more convenient solution is that originated by Fehling, prepared by dissolving cupric sulphate, sodium tartrate and sodium hydrate in water. This test is more convenient because it requires only one solution, but owing to the instability of the tartrates, the solution is not permanent. The tartrate in aqueous solution, being acted on by the light and the alkali, is decomposed, and reduction takes place either at ordinary temperature or on heating, more especially if the solution be slightly neutralized by a highly acid urine. It is not an easy matter to prepare a fresh solution whenever we desire to use it, and we can not rely on an old solution. This objection has been entirely overcome by Professor Haines, who uses glycerin instead of the tartrate to hold the cupric hydroxid (or oxid) in solution, making a clear blue test solution, which does not deteriorate with age. After a time it deposits a slight sediment which does not interfere with the delicacy of the solution, but rather makes it more sensitive for the test. Haines' solution may be accepted as a convenient and reliable representative of all copper tests. In applying the test, boil about one dram of the solution and add six drops of the suspected urine and boil again. If no precipitate forms, add six drops more of the urine and boil again. If still no precipitate forms, cool by holding the test tube under tap. If no precipitate forms, we can safely decide that no abnormal amount of sugar is present, but we should not arrive at this conclusion until the last step in this technic has been carefully carried out, for in certain solutions of dextrose, reduction does not take place until again cooled. I have found that to be true in two cases of glycosuria. I am not prepared to give an explanation for this, nor do I know that one has been offered.

---

* Read at the meeting of the Lee County Medical Association, Dec. 22, 1903.

Another fact which has not been satisfactorily explained is that some precipitates are red, while others are of a greenish-yellow color. The old theory is that the one is the hydrated cuprous oxid. More recently, however, it has been pointed out that cuprous oxid may exist in the two isomeric forms, the red and the yellow. The reaction is equally positive, whether the precipitate be red or yellow.

Should a positive reaction result from the application of the copper test, we can not be certain from this test that the reducing agent is dextrose, for a number of substances will produce the same reaction. Levulose, lactose, maltose, and the pentoses are other carbohydrates which possess the reducing power. Uric acid and creatinin, when present in excess, may reduce the copper solution. Certain synthetic compounds are powerful reducing agents, as glycuronic acid, normally present in small quantity but greatly increased in amount after the exhibition of such drugs as camphor, chloroform, chloral, aspirin, europhen, hydroquinone, urotropin, acetanilid, antipyrin, phenacetin, salol, bromol, salicylic acid, thymol, menthol, eucalyptus, glycerin and the aldehyds. In this era of patent medicines and home remedies, we can not know what our patients might have taken, and must be constantly on our guard. Hippuric acid, which is increased after taking benzoic acid or the benzoates internally, may reduce the solution.

Lastly, I wish to emphasize the alkaptons, which are hydroxy-phenyl-acetic acids ($CH_2[C_6H_2(OH)_3]COOH$), which immediately reduce the copper solutions, and any case in which a very rapid and pronounced reduction takes place would arouse suspicion and should lead to a very careful study of the case. The alkaptons are products of perverted metabolism, frequently hereditary in origin, and have no special pathologic significance, but must be recognized, when present, to avoid error.

It will be seen, therefore, that the reduction of a copper solution merely indicates that we must resort to other differential tests to determine the exact nature of the reducing agent present.

BISMUTH TESTS.

Bismuth solutions are used also and are very conveniently represented by Nylander's reagent. In this solution the addition of KOH to the bismuth subnitrate forms the bismuth hydroxid, and on heating, the trioxid is formed, which may be reduced to the suboxid or even to metallic bismuth, producing a black color or precipitate. Bismuth solutions are not reduced by the alkaptons, therefore they may serve to differentiate these substances from other reducing agents. They are reduced by glucose, levulose, lactose, pentoses and glycuronic acid. Nylander's reagent is very sensitive to reducing agents, but its great fallacy lies in the fact that all proteid compounds containing sulphur, on being boiled, yield the sulphur to combine with bismuth, forming the black sulphid which may be mistaken for the oxid. Not only albumin, but the nucleo-albumin (mucin), which is present in a large percentage of urines, will produce this reaction. Out of one hundred specimens of urine which I have tested, Nylander's reagent gave a black precipitate in fourteen, none of which contained sugar. Therefore, bismuth solutions may be depended on as delicate negative tests, but a positive reaction means very little.

TEST BY FERMENTATION.

The fermentation test is not delicate, because a portion of the CO_2, corresponding to 2.5 grains of sugar to the ounce of urine, is absorbed by the fluid, but it is a useful confirmatory and differential test. Glucose and levulose ferment readily. Lactose does not readily undergo alcoholic fermentation, but rapidly undergoes lactic acid fermentation. The pentoses, glycuronic acid, hippuric acid and the alkaptons do not ferment, and may thus be differentiated from dextrose and levulose, *should the copper and bismuth tests have given positive* results. Again, should the urine, after complete fermentation, still reduce the copper or bismuth solutions, it would indicate that part of the reduction at least was due to glycuronic acid, hippuric acid or alkaptons.

PHENYLHYDRAZIN.

The phenylhydrazin test has been highly recommended, and some eminent authorities state that there can be no substance present in the urine which forms crystals resembling those of phenylglucosazon. It has been clearly demonstrated, however, that glycuronic acid, oxalic acid, carbamid, pentoses and other substances combine with phenylhydrazin, and the crystals formed by glycuronic acid are, from all appearances, exactly the same as those of phenylglucosazon. Maltose, when present, will produce a maltosazon, which very closely resembles the crystals of glucosazon. We have, therefore, three azons produced which must be differentiated, and to do so, we determine the melting point of the crystals. Those crystals formed by glycuronic *acid will melt at a temperature of 114 to 115 C.*; the maltosazon melts at 190 to 191 C.; the glucosazon, in its impure form, melts at 173 to 194 C., but in its pure state, obtained by washing with water, dissolving in alcohol and again precipitating with water, its melting point is 204 to 205 C. The technic of the phenylhydrazin test, therefore, is very complicated, and is not absolutely reliable except in the hands of expert chemists.

THE ORCIN TEST.

By employing the copper, bismuth and fermentation tests we can differentiate lactose, the pentoses, glycuronic acid and the alkaptons from dextrose. The pentoses may further be recognized by the orcin test. For this purpose, M. Bial recommends a solution of ferric chlorid, hydrochloric acid and orcin, and advises that the solution and urine be heated until the first bubbles form, when, if pentoses be present, a green color or precipitate will appear. Boiling may produce the same color if glycuronic acid be present. In preparing the reagent we must be careful to use orcin instead of the orcein, which is a dye made from orcin.

The alkaptons may be recognized by a characteristic test. On the addition of KOH, with an excess of oxygen or more slowly as the oxygen is absorbed from the air, the urine becomes dark brown and finally black, if alkaptons are present.

THE USE OF THE POLARISCOPE.

Finally, we have still to differentiate between a dextrosuria and a levulosuria. It has recently been pointed out that levulosuria occurs much more frequently than has been reported, because most of the cases have been overlooked. In all of the above tests, with the possible exception of the phenylhydrazin test, levulose and dextrose give identically the same reactions, but we can certainly differentiate one from the other by the use of the polariscope. Dextrose deflects polarized light toward the right, while levulose deflects polarized light toward the left. In using the polariscope for qualitative analysis, however, we must bear in mind that (1) maltose is also dextrorotary, but its power of rotation is greater than that of dextrose. It can also be recognized by the fact that its slight reducing property is greatly increased on the addition of sulphuric acid. (2) Oxybutyric acid and diacetic acid are levulorotary, and when present, may modify or entirely overcome the dextrorotary power of dextrose, so that the polarized light may be deflected toward the left in the most extreme case of glycosuria. In such a case, however, we would submit the suspected urine to the polariscopic examination and note the degree of rotation. Then subject the urine to fermentation, and after complete fermentation, repeat the polariscopic test, when the diacetic acid, being unopposed by the dextrose, would deflect the polarized light still farther toward the left.

SUMMARY.

In closing, we may sum up the following conclusions:

1. The copper and bismuth tests are reliable negative tests, but a positive reaction must be confirmed.
2. Trommer's test is not always reliable.
3. Fehling's solution is not permanent.
4. Haines' solution is the most convenient of all copper solutions, and is reliable if the above technic is followed.
5. Bismuth solutions are not reduced by the alkaptons, and serve to differentiate them from other reducing agents.
6. The fermentation test is in itself not characteristic, nor is it very delicate, but it serves to differentiate lactose, glycuronic acid, hippuric acid, the alkaptons and the pentoses, which do not ferment, from levulose and dextrose.
7. If the completely fermented urine should still reduce the copper solution, it indicates the presence of glycuronic acid or alkaptons.
8. Phenylhydrazin test is good, but the technic is complicated.
9. Pentoses may be recognized by the orcin test.
10. Alkaptons are recognized by the characteristic ozonized alkali test.
11. Finally, we can differentiate dextrose from levulose by a polariscopic examination.

Cancer from Corsets.—In the London *Lancet*, Dr. R. A. Lucas describes three cases in which cancer was apparently caused by the friction of the pectoralis major on the edge of the corset. Each case occurred on the right side in a woman whose occupation caused much use of the right arm.

A CASE OF CIRCULAR INSANITY STUDIED FROM CLINICAL, DIFFERENTIAL AND FORENSIC STANDPOINTS.

RICHARD DEWEY, A.M., M.D.
WAUWATOSA, WIS.

WITH GROSS AND MICROSCOPIC ANATOMY OF BRAIN (FROM THE PATHOLOGICAL LABORATORY OF THE UNIVERSITY OF CHICAGO), BY THOR ROTHSTEIN, M.D., CHICAGO.

INTRODUCTION.

The case of X. merits study from several points of view: First, with reference to diagnosis owing to the conflicting opinions expressed by experts during the patient's lifetime, as to the form of mental disease; also in a medicolegal sense, on account of the great number and variety of legal contests growing out of the patient's mental condition, in which he himself actively and often brilliantly participated. The case also incidentally involves the study of a remarkable personality, and the clinical history consists largely in the narration of extraordinary acts, "antics" and vagaries of a mad but acute and brilliant mind. Finally the findings resulting from the examination of the brain present much of interest in both a positive and negative sense.

The following statement of the case has been prepared from personal observation of the patient when under my care in the State Hospital at Kankakee, Ill., in 1889 and 1890; from information given by himself in lucid periods and by family and friends; also by colleagues who observed the case; also much information has been gained from the public press.[1]

There is something lacking in completeness, owing to the fact that from 1899, when he was under my care, to 1901, the year of the patient's death, only cursory examination was secured by me.

PRELIMINARY HISTORY.

X. was born in England in 1856, and came to Chicago at 14. His father, a retail grocer, a man of unusual ability and originality, was a victim of alcoholic excesses at periods in his life, but reformed, and for twelve years kept temperate and spoke eloquently in the cause of temperance. He relapsed, and was also addicted to drug habits in his late years, and died during the patient's boyhood. His paternal ancestors, according to the patient's own statement, "for many generations were drunkards, dissipating their estates and drinking themselves into their graves." His mother, though thought to be consumptive at patient's birth, became strong and well, and now enjoys good health at an advanced age. Musical talent is a characteristic of the mother's side (For fuller anamnesis see *Status præsens* below.)

The patient in early life showed much precocity. In infancy he was believed to be affected with hydrocephalus. He had three brothers who died in early life, it is supposed of hydrocephalus. The patient's activity of mind is illustrated by the fact, stated by his sister, that at 5 years of age he had read Scott's Ivanhoe five times through. He was bright at school, and seems to have easily kept with the first in his class. He relates that when graduating in the public school and receiving some decoration for his proficiency, he resolved to seek a position on the school board of the city, and he realized his ambition in a few years. He became a successful attorney, and took an active part in politics and in social life, enjoying much popularity, though generally considered an exceptional character.

---

[1] A scrap book of press clippings in my possession makes about 40 newspaper columns and is far from complete.

The patient had always been subject to marked attacks of what he called the "blues," and was alternately elated and despondent in more than an ordinary degree, and often without reference to any external reason. He worked hard and almost uninterruptedly in his profession for ten years, taking very little relaxation and contesting his cases in court with unusual skill, force and persistency.

In 1885, at 29, the patient had what he called a "nervous breakdown," and was advised by his physician to take a long journey for his health. He had been actively engaged as an attorney through the battle of the C., B. & Q. Railroad with its locomotive engineers, acting as legal assistant, and during the strike was at times, according to his own statement, in positions of danger and difficulty.

Fig. 1.—Normal. Aged 31 (1887).

In the spring of 1887 he went through an exciting political campaign. The candidate for mayor whom he opposed was elected, and the patient lost his position on one of the city boards, and was for a time in what he describes as "mental collapse." He recovered soon from this, and in the summer of that year attracted considerable attention by the manner in which he performed the function of presenting to Queen Victoria the "Jubilee Address" of an association in Chicago, to which he belonged. He went to London, and by his persistence with both the home and foreign offices, and by securing the assistance of the American legation and by using the cable freely, finally secured an interview with the queen and had the satisfaction of being received by her at her residence, Osborne House, on the Isle of Wight, presenting his address and receiving a polite written reply from her in response.

After the patient's return, he caused a magnificently bound and printed volume to be published containing the address to the queen and an account of his reception, with full-length portraits of both the queen and himself included in the volume.

FIRST MANIC-DEPRESSIVE CYCLE.

The patient next drew on himself general attention in Chicago in the spring of 1889 by his exploits in the campaign for the election of city officers. He entered actively on the canvass, especially in opposition to a certain candidate of his own party, on whom he made very successful war. To illustrate his mental state, I will give some extracts taken from a pamphlet published by the patient, the introduction on which compares him with Don Quixote and General Boulanger, and says: "No such character ever before challenged attention." "Let him alone and he will be president and king of England, both *at once*." His proceedings during the election are then described in part as follows:

> The biggest man in Chicago last Wednesday was X., also the proudest and happiest. The headquarters of both parties were nothing in comparison to his law office. He was overrun all day long, and for everyone there was a royal welcome. Everyone, friend or foe, got a word of cheer and a cigar, the like of which *grows not* outside Havana—a 50c "Jack Rose," fresh and fragrant, and with a delicious odor of victory about it. . . . He invited some of his intimates to a little love feast at Billy Boyle's. . . . English chops and juicy roasts were washed down with Mumm's of the extra dryest kind. When the company finally separated X. agreed with F. W. to sail with him *soon* for a pleasure trip to Europe. Not only had he won glory, but a mint of money. Over and above expenses he had the snug sum of $10,700 to his credit by the Democratic victory Tuesday.

He describes his exploits as follows:

> On the morning of election I arose at 5 o'clock and was on horseback for eleven hours. I went from poll to poll. I would gallop up to a precinct, offer to bet $1,000 to $500 against W. and generally encourage the boys. At one polling place I came across a strolling band of Italian musicians that I at once hired for the day. One of the places visited was the ——— Club. It was ladies' day and the club was thronged. They all came to the windows, waving their handkerchiefs and throwing kisses to me. I next stopped at the ——— Club House. The members all came running to meet me, headed by my dear friend C. H. I marched into the club to the tune of "Hail to the Chief." We paraded through all the rooms and I instructed the steward that from that hour forth until next morning nobody could have anything from the bar to eat or drink or smoke without charging it to me. We went down to my house. My dear wife and my dear old mother—God bless her—and my children were standing on the steps, and the neighbors were all in their windows, and hundreds of people were in the street. The band played "Hail to the Chief," I saluted my family and friends, paid my men and went in. I immediately sent an order to G. & M. to send up several cases of champagne to the ——— Club, telephoned the Garfield Park Rosery for a hundred dollars' worth of flowers, and engaged the full Valisi mandolin orchestra to play there.

It was in the campaign above described that X. was believed to have received an injury of the head from an assault made apparently by hired thugs attacking him when passing a dark alley. Accounts differ as to the extent to which he was injured, but he was undoubtedly attacked and knocked down and received a contusion of the left parietal region, causing some swelling. He was not rendered unconscious, and a medical friend who saw him immediately after, states that the injury was slight. It is probable undue importance was subsequently given this circumstance on account of the natural desire to find in it a cause for the insanity. It is not impossible that the concussion of this wound aggravated his natural lack of balance, but the postmortem showed that no visible traces of injury from it were present. It is certain that a considerable degree of mental exaltation (and later depression) followed the above-described campaign. X. began to show a disposition toward great extravagance, giving extraordinary presents for number and value to his friends, purchasing silk umbrellas, canes, etc., by the dozen and giving them away and buying suits of clothing for himself in the same manner, also scattering flowers in profusion among the ladies.

About this time he again announced his intention of starting for Europe. Every effort was made to dissuade him, but without avail, and when he went to New York, before sailing and while waiting there, the idea was seriously considered by his friends of committing him to some private asylum. This fact became known to the patient, who scoffed at the idea of being examined by physicians, but expressed his willingness to meet them and entertain them at dinner, and I understand that three gentlemen (one of whom was Dr. E. C. Spitzka) met him in this way, and after seeing him, agreed that he was in the early stages of an attack of insanity, but that in his present state no court would sustain an attempt to interfere with his freedom. One of the experts believed he was in the incipient stages of paresis. Of the opinions of the others I have no knowledge. X. himself assured his friends that he would oppose any attempt to interfere with his liberty or place him under control. He went to London and was absent a few weeks, passing through a brief normal interval, but his period of depression began to come on. His condition after his return home is described by the patient himself as follows:

> On my return home I was undoubtedly a victim of that variety of insanity called melancholia. I had always been subject to the "blues" periodically, but at this time I thought I was bankrupt, although I was worth, as it is estimated, at least $200,000. I thought my business had left me and could not concentrate my thoughts and mind on anything except my own trials, and finally, tried to assassinate myself, like a fool (referring to an attempt at suicide, it is supposed). I was sent to the sanitarium at Wauwatosa, where I thought I was followed and surrounded by the Clan-na-Gaels and that the defense of the Cronin trial (then going on in Chicago) would be that I was a British spy—a Le Caron—and that I, with the help of my English friends, killed Cronin in the interest of the English government to besmirch the Irish leaders and throw the guilt on them.

Dec. 7, 1889, X. was brought from Wauwatosa to Chicago and found insane by the County Court of Cook County, and committed to the Kankakee Hospital for the Insane.

STATUS PRÆSENS. EXAMINATION AT HOSPITAL.

It was at the time of X.'s commitment to the hospital at Kankakee that he came under my personal observation. Particulars with reference to the condition of the patient were as follows: Native of England. Parents born in England. Father and paternal ancestors for several generations said to have been addicted to alcoholic excesses. Father, a grocer; also exhorter in M. E. Church, addicted also to drug excesses. At one time temperate for several years and eloquent speaker for temperance reform. Three brothers of patient alleged to have died in infancy of hydrocephalus. Mother in good health at advanced age; marked musical talent in mother's family. Mother at time of patient's birth thought to have been tuberculous.

Patient's recent habits in regard to alcohol and tobacco excessive. Age, 34; married; three children; one died suddenly in infancy of obscure brain disease; occupation, attorney; education, high school; weight, 178 pounds; height, 5 feet 8½ inches; head large but symmetrical; size of hat worn, 7 11/16; eyes blue; pupils normal; complexion fair; physically muscular, stout and robust and thick set; no stigmata of physical degeneration; neck large and short; tongue clean; appetite capricious; digestion good; bowels constipated; sleep irregular; state of special senses and their organs normal. Cutaneous, tactile and reflex sensibility normal, except the tendon reflexes somewhat diminished on right side; heart, lungs and pulse normal; genito-urinary system normal; no evidences of syphilis; mental state dull and depressed and silent. State of memory, perceptions and reasoning power unascertainable, but evidently much weakened; volition impaired; manner vacillating.

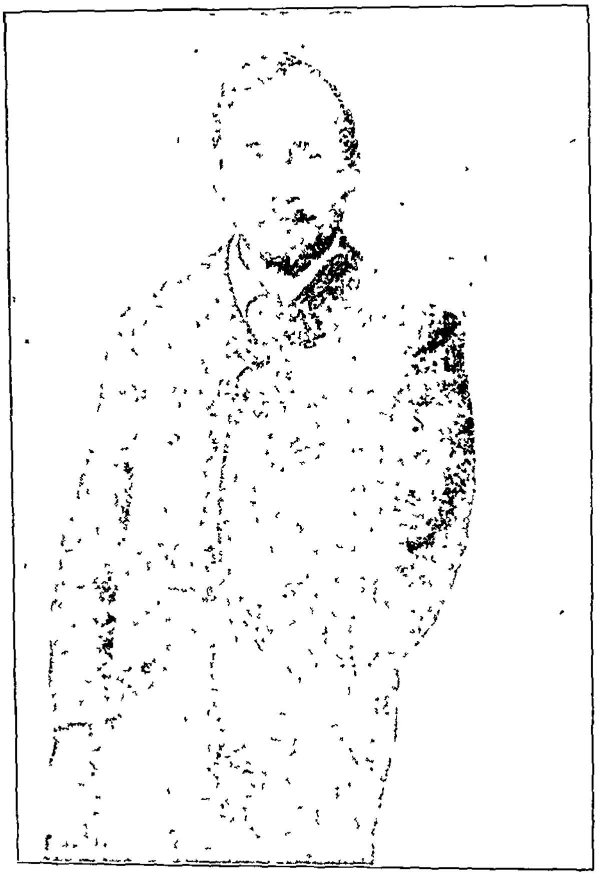

Fig 2—Depressed state. First cycle, aged 34 (January, 1890).

The following are notes with reference to the patient's condition:

Dec. 8, 1889. Patient dull and demented. Walks mechanically about the ward or sits by himself, having little to say to anyone. Marked retardation in movements and ideas. Does not give expression to delusions (he afterward described as having at this time the idea that he was suspected to be a British spy by the Clan-na Gaels.

December 16. Depressed, but better. Realizes his condition and speaks of his mind as being "muddled."

Jan. 1, 1890 About the same. Does not care to see anyone and does not want to leave the ward—even to go walking. Appetite good. Physical health good. If friends call to see him avoids them and tries to keep out of their way.

January 20. *Much improved.* More cheerful. Talks very freely and worries considerably for fear people will not have confidence in him when he goes out.

January 30. Much improved. Cheerful most of the time. Thinks he is about well and talks of going home.

February 11. Very cheerful. Clear mentally. Has no delusions.

February 25. Cheerful. Says he never felt better in his life.

Normal Interval.—Toward the end of February patient was in very good spirits, but not to an abnormal degree. The coming of the World's Fair to Chicago (which was determined at this time), where he had property interests which he believed would be favorably affected, seemed to exhilarate him considerably, but naturally.

March 5, 1890. *Discharged.* Condition sane and normal to all outward appearance. Patient advised to remain longer at hospital, but, inasmuch as there was nothing in his condition warranting detention, he was discharged, especially as his determination to go was unalterable.

About the time of his discharge the wife of the patient stated to me that she had observed periodically a rather regular fluctuation in his mental condition. She believed that there had been for many years with much regularity periods of alternate depression and exaltation, averaging about five months each with a month of natural condition between.

SECOND MANIC-DEPRESSIVE CYCLE.

Within two weeks after his release, patient began to attract attention by his eccentric conduct. He appeared in a political convention dressed in riding boots and otherwise striking apparel, and went on the stage, whip in hand, to denounce a certain candidate.

He was next heard of in Omaha and Kansas City. In one of these towns he insisted on singing "Annie Rooney" in the street, and was arrested as disorderly after a lively encounter with the police, and spent the night in the station. The papers stated that he rode on horseback up the steps of a house and pulled the bell; also that he was ejected from the stage of one of the theaters. He showed an extreme degree of sexual erethism. These things might be attributed to drink in part, but did not differ in any degree from the action of the patient both before and after, when it was impossible for stimulants to have been a factor in the case.

The patient was induced to return to Chicago, and his condition was such that his friends immediately took steps for his recommitment to the State Hospital at Kankakee, where he was again committed by the court after an absence of about one month, and on the second admission he presented a marked contrast to the condition existing when discharged one month before. His physical condition was not changed, except that he was perhaps more robust and florid,[2] but he was in a continuous state of exhilaration and restless activity, sleeping little except under the influence of hypnotics. There was now scarcely a trace of any delusion except in his exaggerated ideas of property and self-importance. His insanity was shown in his conduct more than his ideas. He was remarkably quick and brilliant in use of his mental faculties, memory accurate, logical power great, fancy, imagination and gay emotions were all highly efficient. He was, as shown later, capable of great power of attention and severe and long-sustained mental effort, as would scarcely be possible in paresis. He was irrepressibly good-natured, though occasionally having outbreaks of rage at being interfered with. In his walks over the country, around the hospital with attendants, he purchased all the real estate and stock in sight. He offered to engage at large salaries many of the attendants and officers of the hospital for his personal service. He was markedly erotic in his impulses and actions. Within a few days of his admission he was granted a hearing on application for a writ of habeas corpus. His conduct in the court room was highly eccentric, but entertaining. During his presence in the court room the grand jury were brought in to be sworn, and as they stood in a row before the judge, X. interrupted the proceeding, addressed them and stated he would subpena them all as witnesses to his sanity. He also volunteered his assistance to an attorney in a suit then in progress, correcting the attorney's mistakes and showing both ability and brilliancy in striking contrast to the blundering of counsel. When presenting his application for a writ, he was told by the judge that the case would be heard "to-morrow," whereon the patient replied: "Your honor, I stand on my constitutional rights and refuse to agree to any postponement." The judge then agreed to hear the case at once, and X. assured him that he would "do as much for him if their respective positions were ever reversed," as he (X.) expected some day to "be on the bench" himself.

After the hearing the court remanded the patient to the custody of the hospital, and, after being remanded, X. remained in a state of continuous maniacal excitement until well on in August. He was at times violent, destructive and untidy in his habits. His physical condition remained as above described. There were still no evidences of motor or sensory abnormalities, depending on any structural lesion. Though his mental condition was suggestive of paresis, it was also entirely consistent with the theory of simple maniacal excitement.

From March 31 to June 24, 1890, when X. was released by habeas corpus proceedings in Chicago, he was in an extraordinary maniacal condition, but withal very brilliant and resourceful in his mental action. (See Fig. 3.) On one occasion when out in the grounds he suddenly gave his attendant the slip and dashed into the river. He went out some distance into the water and informed all who came near that he would drown them or himself, or both, if they attempted to bring him in. He was finally secured by having an attendant make a rush for him, having a rope tied around his waist, one end of the rope being in the hands of persons on the shore. The latter grasped the patient firmly around the body and both were then safely drawn ashore.

During this time the patient seemed to believe that if he should, as he expressed it, "raise merry hell" and be sufficiently violent, obstreperous and destructive, this might effect his release from the hospital. He also sought to appear in the rôle of one who is not only illegally confined, but also shamefully abused, and was constantly sending applications to the courts to be heard on writs of habeas corpus, representing himself as the subject of outrage. When quite alone in his room in the hospital and seeing persons pass by in front of the building near his window, he would throw himself on the floor and strike and pound the floor with his own body, to make as much noise as possible, and at the same time call out in pitiful and pleading tones, "For God's sake, release me!

---

[2] He always took on flesh during maniacal periods, as stated by Dr. Sanger Brown, contrary to usual experience, and at one time attained a weight of 375 pounds.

You are killing me with your abuse! Murder! They are killing me!" His outcry was such that a stranger would naturally imagine some one was being grossly abused. He wrote a letter, signing his sister's name, saying his mother was dying of heart disease, and wanting her son to come home at once to see her for the last time. After violently attacking attendants, necessitating a severe struggle, he would complain bitterly that he had been brutally treated, and at the same time write a letter describing the scrimmage and extent to which he had punished the attendants, adding, "I kicked two in the head and never got a scratch."

At the time of his hearing in June, on a writ of habeas corpus, he appeared in glasses and stated on the witness stand that one of his eyes had been injured by abuse at the hospital and an oculist had expressed fears that it was permanently injured, when, in fact, as I learned from the oculist whom he consulted for glasses, he had not mentioned that his eye was injured in any way. During this period his exaggerations were remarkable. He would simulate bowel trouble and allege soberly he had had over 100 evacuations in a day. The attendant reported that this was done in order to secure liquor or medicine. He alleged he was continuously closely confined 27 days when never more than two passed without his being out in the grounds for exercise. He was markedly kleptomaniacal in his propensities and everywhere he went he would take possession of all movable articles, no matter whether their value was great or small. He would entirely clear the office of pens, pencils, stationery, postage stamps, mucilage, paper weights, etc., when allowed to go into them. Among other things he carried off a bottle of red ink and soaked his hat in the ink. He also decorated it with many ribbons and streamers and wore it about the grounds. He frequently wrote orders and notes and signed the superintendent's name to them, and occasionally the orders were so clever a forgery that they would have been carried out but for the singular nature of the instructions.

In the latter part of June, 1890, X. succeeded, as stated, in being again granted a hearing in the Circuit Court of Cook County on his application for a hearing under a writ of habeas corpus.

When his case came up in court, he took the stand and made a rather telling statement, representing that his wife, from interested motives, wished him out of the way, that he had been brought back from the west by deceptive telegrams in order that he might be "railroaded" into the asylum. (It was true a telegram had been sent him that one of his children was sick in order to induce him to return.) He had met during his two or three days in Chicago before the hearing scores of his former acquaintances, and almost all agreed that he might be a little eccentric, but he was by no means insane, and promised to testify for him. Of the people numbering fifty or more who did testify that he was sane a few really believed it and thought him a much wronged man. Others complied with his request out of good nature. Still others from fear. When the hearing was over, the judge made an order releasing him, though stating at the time that he had doubts about his sanity, and the judge sent word to the probate court having charge of X.'s property that he did not think the control of his property should be restored to the patient. At this juncture X. was, in the eye of the law, a sane man when standing in the circuit court before Judge Collins and a lunatic in the probate court in the presence of Judge Kohlsaat. The judge also explained that the state of public opinion and ignorance of insanity were such that if he remanded X. to the hospital it would have the appearance of an outrage on personal liberty.

After his release the patient began a career of wild and eccentric conduct. He took his own and other young children to theatrical entertainments and kept them out until midnight, while their mothers were at home in alarm. He visited hotels and accumulated bills which he could not or did not pay. He in one instance offered to leave his children as security until he should pay a hotel bill. He was arrested for assaulting a telephone boy and given the alternative of paying a fine or going to jail. He would address ladies at hotels and on the trains who were perfect strangers and ask them to drink wine with him, and would repeat poetry to them. In spite of his antics he was much of the time an amiable and interesting companion. Flashes of wit and entertaining talk flowed from him spontaneously. There was not the slightest sign of mental weakness, but quite the reverse. In accurate memory, logical power and concentration of thought and attention he was unusual. His handwriting was slovenly, but what he wrote was always clear and cogent. He dressed himself in a way that attracted attention, wearing blue and red silk sashes, knotted and hanging nearly to his knees, and embroidered silk shirts and an undue number of scarf pins and other ornaments. One of the strongest evidences of his lack of mental balance was his utter inability to control or realize the effect of his actions, since, if he could have comprehended in the least his real position, he would have felt the necessity of moderation and sobriety, which would in some measure regain the lost confidence of his friends and the public. This he fully appreciated previously in his depressed state, and had repeatedly expressed the idea that he had been doing "a large business on a small capital;" in short had been a great fool, and feared he could never again command any confidence.

X. continued his fantastic conduct until he was again arrested in August on a new complaint of insanity and a new inquest was instituted *de lunatico*. This trial was noteworthy for the brilliant defense he made of himself, conducting his own case, and examining the witnesses in a style that placed the most learned experts at an apparent disadvantage. He furnished racy entertainment to a crowded courtroom of spectators whose active sympathy was with him and in whose opinion the alleged lunatic showed more brains than those who assumed to pronounce him insane. He was perfectly at home in the court room, inimitable in his style of conducting his case, and also displayed for a layman a surprising amount of expert knowledge in reference to insanity. In this trial the fact came out that opinions differed with reference to the form of disease with which X. was affected—a fact of which he made very telling use before the jury. Most of the witnesses claimed that he was a subject of "paresis," while others declined to state the form of disease or gave the opinion that it was *folie circulaire*. Having to examine an alienist who had pronounced him a paretic, he elicited the leading symptoms of paresis—impaired speech, unsteady gait, difference in pupils—and then exhibited to the jury his own perfect enunciation, steady movements and asked the witness to examine his pupils, compelling him to admit they were normal, and challenged him to pronounce a sentence composed of any catch words as well as he himself could, exhibiting his glib enunciation to the jury. To one of the experts who had examined him years before and who now pronounced him insane, he said:

Doctor, did I ever pay you for examining me? I do not recollect about that, but I'll do so now if you will prove that your services were worth anything.

In another case X. said to one of the experts:

Doctor, I suppose it would be impossible for me to convince you that I am a sane man, would it not?

Yes.

Well, then I won't try.

With one medical witness he had this conversation:

Don't you think that Dr. ———, who had me in charge from December until March last, had a better opportunity to notice my symptoms than you had?

He may and may not have had.

Dr. ——— says I have circular insanity. Is that so?

No; in my judgment I think not.

Then I have got you and Dr. ——— against each other.

This difference of opinion enabled X. to score an effective point with the jury and with the public.

Fig. 3.—Exalted state. Second cycle, aged between 34 and 35 (June, 1890).

Being myself subpenaed as a witness, I testified as follows:

I think that X. is now in a state where his insanity is not easily recognized. However, there are things which convince me of its existence. I understand that he is by nature high-minded and truthful to the average degree. From what I have learned of him of late he is now the reverse of all this. His judgment is seriously impaired. While his mind is shrewd and cunning, and even brilliant, and his memory accurate in many matters, he fails in the exercise of ordinary judgment or common sense. X. does not at first sight appear to have illusive ideas, but on closer inspection he is seen to have these, as for instance, in his extravagant notions as to his property and as to the light he is held in by others. He told me, for instance, within a few days that he was going to run for congress this fall; that he was going to England as an envoy for the directors of the World's Fair; that he was to be attorney for the board of education; a member of the library board; and was also to be appointed on the board of trustees of the institution at Kankakee.

The inquest *de lunatico,* after lasting three or four days each week for three weeks, was terminated by the act of the judge in dismissing the case. On this occasion I had been recalled for cross examination, and, immediately on entering the courtroom saw that there had been a change in X.'s condition. He was now quiet and moderate in his speech and action. His former jaunty, jocular, "larky" air and disposition had disappeared and he seemed precisely as he was at the time when I discharged him the preceding March.

NORMAL INTERVAL.

I readily admitted that I saw nothing outwardly insane in X. at that time. The court, after this testimony was finished, stated that he would now bring the case to a close by withdrawing a juror, as he believed no reasonable person would entertain the idea that X. was insane after hearing his brilliant defense of his case.

At the time when this remarkable trial came to an end a great amount of interest had been aroused in favor of X., and it had been arranged to hold a public meeting for the purpose of endorsing him in his "fight for liberty" and of raising funds to assist him, if it became necessary to do so.

The trial came to an end opportunely for the patient, for it would have been impossible for him to appear in the character of a sane man very much longer. His phase of depression was now coming on rapidly and he went home from the courtroom to remain there, scarcely leaving the house for several months. He was profoundly despondent and possessed with the idea of some impending calamity. His friends consulted me as to the propriety of sending him to some asylum and stated he was in a condition of misery and suffering pitiful to behold. He gave no attention to business, but sat in the house. When there was any call at the door he would hasten to be the first one there, stating that he was ready, or wanted to meet some (as he thought) approaching disaster. It seems probable from his conduct that he had delusions of persecution. Here I may mention that it was usual for him to become slowly more stupid and inactive, to lie in bed, to keep his room dark, to be extremely filthy in his habits, to refuse food and to talk of suicide.

This condition continued until about March, 1891, when X. was again for a short time rational. He appeared again in public and opened an office for the practice of law. But the swinging of the pendulum to the opposite extreme was again begun, and the story already detailed of weeks and months of wild, fantastic conduct was again repeated with slight variations in detail.

THIRD MANIC-DEPRESSIVE CYCLE.

Through the month of March and up to April 28, 1891, when he was again found insane in court, X. produced a succession of sensations. He was ejected from hotels. He entered his wife's apartments through a window and carried off a quantity of jewelry. He stood at street corners and presented bouquets to ladies passing by. He had a violent scuffle on a street car with a gripman; appeared in a barber-shop minus boots, hat and coat; was obstreperous in barrooms and insisted on every one drinking with him.

To the first medical witness testifying to his insanity in the trial of April, 1891, X. said:

Dr. ———, I met you when you testified against my client

> in the case of B. vs. C. in 1877, didn't I? You say I am insane. Can you point out any case of insanity similar to mine, and can you really tell whether I have paretic mania, or circular insanity, or a sore throat, or corns? You doctors are amusing cusses. You bury your mistakes, while those of us lawyers are filed for record.

The witness replied:

> I'm sure you are insane, Mr. X., but I can not classify your case. It's constitutional insanity.

A verdict of insanity was now rendered, but two philanthropists who had become interested in X.'s case and thought they could care for and benefit him, interceded with the court to be given charge of him, and were allowed by the court to assume this responsibility. The sequel to the efforts of these benevolent gentlemen was what might have been expected. Within two or three days X. was again in the county jail and applied again for a writ of habeas corpus, but was refused by several judges in succession. He was now compelled to return to the Detention Hospital to await his transfer to some institution for the insane. It was for several weeks, however, found impossible to secure his admission to any public or private asylum, though application was made to a large number. It became impossible on account of his violence longer to care for him properly in the Detention Hospital and he was transferred to the county jail and finally to the Cook County Asylum for the Insane at Dunning, and was there during some months in a maniacal state. He gradually improved and was allowed to go about with an attendant on the country roads, where he amused himself by playing Robin Hood and "holding up" every person he met with a demand for cigars, money or plunder of any sort.

NORMAL INTERVAL.

He now gradually became more rational and quiet and was finally released "on probation" October 21. During the winter of 1891-1892 X. was again in a depressed and inactive state, again approximating his natural condition in the early spring, and passing through a customary normal interval.

This was followed by a gradual return of the maniacal cycle.

FOURTH MANIC-DEPRESSIVE CYCLE.

During the summer of 1892 a succession of his customary pranks and depredations attracted public attention, furnishing amusement or annoyance, as the case might be. He was arrested for disorderly conduct and for disturbing the peace, and appeared in absurd or equivocal situations and adventures in towns and cities of Illinois and surrounding states, especially gaining notoriety by his exploits at the National Republican Convention at St. Paul. In the summer or fall of this year X. was again committed to the Cook County Asylum for Insane, passing through the usual maniacal exacerbation. When his condition had become more quiet he one day made his escape with the assistance of a woman who drove through the grounds and took him into her carriage. This escape was planned by assistance of outside persons and a disguise furnished X. consisting of a woman's clothing. The winter of 1892 and 1893 appears to have been uneventful, and apparently in the spring of 1893 the usual "March madness" did not occur. X. went to Colorado in the summer of 1893 and made special effort to control himself with a view to regaining control of his property. which was still in the hands of a conservator. He was at this time more mildly maniacal, though, while stopping at Colorado Springs, he attracted much attention and at times people avoided the Pike's Peak cog-wheel railroad trains when he was aboard and the hotels and public places where he disported himself. From this time there was greater irregularity in the cycles and the normal intervals were less marked. At the meeting of the American Medico-Psychological Association in Chicago in June, 1893, he attended one of the sessions and requested to be allowed to address the association, and while sitting in the meeting fell asleep in his chair. He had grown very gross and corpulent. There appears to have been from this time a more decided moral and mental deterioration. Though he still at times was brilliant and able to carry on spasmodically a law business consisting largely of habeas corpus proceedings and attempts to release patients in asylums, he never equaled his former achievements, and evidence of degeneration was shown in many acts, foreign to his normal self, of an indecent or quasi-criminal character.

(To be continued.)

A CASE OF PARASITIC HEMOPTYSIS OR INFECTION WITH THE DISTOMA WESTERMANII.

A. D. MACKENZIE, M.D.
Attending Physician to St. Vincent's Hospital.
PORTLAND, OREGON.

The value of the examination of sputum for tubercle bacilli depends almost solely on their presence, and it is generally recognized that repeated failure to find them does not exclude the existence of tuberculosis in the lungs.

This fact is intimately connected in its relation to differential diagnosis, with the characteristics of the sputum in parasitic hemoptysis, for in this disease some of the general symptoms of tuberculosis, such as emaciation, general weakness and anemia, are usually associated with the continued expectoration of blood-stained, mucopurulent material. There are obvious reasons, especially applicable to certain parts of the United States, why parasitic hemoptysis should be excluded in cases suspected of being tuberculous, and in which the sputum is free from tubercle bacilli, although it continuously possesses various admixtures with blood.

This is illustrated by the following account of a case admitted to my service in the St. Vincent's Hospital of Portland, Oreg. It is, so far as I am aware, the first instance of parasitic hemoptysis observed on this continent.

History.—A Japanese man, a native of the province of Okayama, was admitted Nov. 23, 1903, suffering from weakness and persistent hemoptysis. He arrived on this continent the preceding April and had been employed by the fish canneries of Vancouver and Victoria during the summer.

His first attack of hemoptysis occurred July 17, 1903, while rowing a boat against a strong tide in the Columbia river; four or five ounces of blood, described as bright red, escaped by coughing. A cough with blood-stained expectoration continued after this attack, with slight intermissions, until he applied for admission to the hospital. Friends accompanied him to the hospital, desiring assurance that he did not have tuberculosis.

Examination.—At the time of admission he had lost some weight and complained of slight transient pains in both sides of the chest, in front and behind, and varying from day to day in location. On examination cogwheel respirations and a hemic murmur were found; the chest was well developed. Although the chest was carefully examined at different times during his stay at the hospital, both by myself and by other members of the attending staff, the few alterations mentioned were not supplemented.

During his stay in the hospital blood was always found in the sputum; for a time it resembled pneumonic sputum, later a microscopic examination was necessary to find the blood. At times there were found little yellow particles in the sputum like plugs of bronchioles; they were frequently tipped at one end with clotted blood. Repeated examinations of the sputum were made for the tubercle bacilli with uniformly negative results. There were no accounts of tuberculosis in the family history and he had never been sick before; with exception of gonorrhea several years before, from which recovery was prompt.

The ova of the distoma were finally found in the sputum and their nature confirmed by Dr. C. W. Stiles of the U. S. Bureau of Animal Industry; Charcot-Leyden crystals were also abundant.

He had no temperature, ate and slept well and gradually so recovered that longer retention in the hospital was impossible. The hemoglobin was 70 per cent. (Tallqvist) and examination of the corpuscles of the blood revealed no noteworthy alterations in number or character.

There are recorded three instances in which observations have been made in this country of pulmonary infection in animals with parasites of this variety, the first by Ward[1] in a cat, the second by Kellicott and Ward in a dog, the third by Payne and other members of the Bureau of Animal Industry in hogs. These observations have formed the basis of a number of publications, of which those by Ward, and by Stiles and Hassall, deserve special mention. The infection in hogs was observed in Cincinnati where, for a period in 1898, 1 per cent. of the animals inspected were found infected. The flukes found in the cat concerned an animal of Ann Arbor; those in the dog were found in Columbus, Ohio.

In other countries, other observers, including Kerbert, who named the parasite after Westerman, have found it in the lungs of the tiger. In Japan, dogs and cats both serve as final hosts. Although there are differences noted in the descriptions of this trematode, as it occurs in man and animals, the reasons for considering that separate species have been described are as yet insufficient. Likewise the Asiatic and American forms are believed to be identical, although, as stated by Stiles, a zoologic error may be made, in so doing, in the interests of hygiene.

There is every reason to believe the infection in the case here reported was contracted in Japan. The disease is endemic in the province Okayama from which he came; in fact, it was to this province that Yamagiwa and Inoui were sent by the Japanese government in 1890 to study the disease.

Most of the writings concerning the disease have been by the Japanese, and unfortunately they are, to a large degree, in that language. Two of the articles by Yamagiwa,[2] one by Katsurada,[3] and the recent one by Taniguchi,[4] however, are in German, and contain references to the accounts of many of their countrymen.

As at present understood, the *Distoma* or *Paragonimus westermanii* is responsible for two widely different forms of disease in man—the pulmonary and the cerebral. In both, cysts are likely to be found as the chief anatomic change. Those in the lungs are usually in the upper lobes and near the surface where they may form brownish or darker projections. Their shape is described as flat (Yamagiwa) or round (Katsurada), and their size about that of the tip of the little finger. When they contain parasites there is also a viscid brownish-gray fluid, and the lining is rough, ragged or wrinkled. They rarely contain more than a single worm in man. Their firm walls measure a millimeter in thickness, and are formed solely by the tissues of the host.

Participation of the bronchi and bronchioles in the formation of such cysts by dilatation was demonstrated by Katsurada in dogs and cats, but not in human lungs, although these channels always lead into the cysts. In the lungs so infected a bronchitis occurs with a mucopurulent and hemorrhagic exudation, as well as various forms of pneumonia, depending on the stage of the infection and on repeated infection. The nodules forming about the ova are said to simulate chalicosis, and in one case (Case 1 of Katsurada's article[3]) the lung was very cirrhotic from the disease; bronchiectasis and emphysema may be consecutive changes. Nodules inclosing ova and resembling tubercles may occur in the pleura.[5]

Considerable interest is connected with the origin of cysts in the brain on account of the degree to which the softening following embolism is responsible for their formation. They are described as varying in size from a grain of rice to a pigeon's egg, or larger, and communicating.[6] In one case no cavities occurred, but instead dark fibrous nodules inclosing ova.[2]

In the cerebral cysts, or more correctly, pseudocysts, both adult worms and ova have been found. In 11 cases of parasitic hemoptysis, in which Inoui observed cerebral symptoms, there were six in which the unilateral spasms were in some cases accompanied by paresis, two with general epilepsy, two with hemiplegia and one with psychic blindness.[4] In the case reported by Taniguchi, in addition to the usual symptoms of epilepsy, those of athetosis and chorea were present. His anatomic study of the brain lesions led him to believe the walls of the cysts were, in part, formed by the vessels by which embolism occurred.

[5] In Miura's description of such nodules in 1899 (Virchow's Archiv, cxvi, 310), the ova are mentioned as being those of the common liver fluke; this has been corrected by subsequent writers.

[6] I have been unable to find any account in Miura's article of the cerebral infection referred to by Stiles and Hassall.

In other parts of the body either the ova or worms have been found in the liver, orbital cavity, lower eyelids, scrotum, mesentery, diaphragm, omentum and in the contents of the intestine.

Thirty-one of the ova were measured by Dr. E. R. LeCount of Rush Medical College, Chicago, care being taken to select such as were yet unbroken.[7] The sizes (see accompanying table) were found to correspond fairly well with the measurements given by most authorities, particularly those of Katsurada.

ILLEGITIMACY AN ECONOMIC PROBLEM.

JAMES E. DAVIS, M.D., PH.G.
Obstetrician to Mercy Hospital and to Salvation Army Rescue Home.
DETROIT.

> "To such grievances as society can not readily cure, it usually forbids utterance on pain of its scorn; this scorn being only a sort of tinseled cloak to its deformed weakness."—Currer Bell, quoted by Shirley.
>
> "The duty of Christian society is to find its work and to do it."—Carlyle.

"Society is organic; that is to say, it is like an organism, in that it is composed of interdependent parts performing functions essential to the life of the whole."[1] The conservation of the race when economically considered, begins with the personal unit, which has both known and unknown values. The unknown unit, plus environment and heredity, represents a known quantity, which becomes a factor in the product of society. Environment and heredity are always subject to the qualifications of "accidentals," which may be either voluntary or involuntary.

"Clear knowledge is confused when we can not distinguish the parts and qualities of the thing known, and can only recognize it as a whole."[2] Thus it follows that it is the "accidentals" which are the confusing factors in our political science. "The life of society may be conveniently divided into eight parts, called life-spheres, viz.: (1) language, (2) art, (3) science and education, (4) family life, (5) social life in the narrower sense, that is, the intercourse of friends and associates; (6) religious life, (7) political life, (8) economic life."[2]

The problem of illegitimacy has a vital position in six of the eight spheres. The personal unit may or may not be privileged a volitional environment; a specific example of the first would be that of the child which chooses a new home with foster parents and a changed society life before his sexual education begins. The resultant changes will be commensurate with the fixation processes of the environment, and the contrast of the two possibilities will be less or greater as the heredity is paralleled or opposed. Add to this the compliment of accidentals, which is subject to the same law as heredity.

The example of denied volitional environment will, as a rule, trend toward a phase of life having the least resistance, which has, in most instances, been made by heredity. The possibility of accidentals that parallel the hereditary taints is greatly increased.

Heredity may be either primary or secondary to environment. If primary, then it follows that the heredity had its beginning in the class of accidentals. To exemplify, it is sufficient to instance the accidentals which occur in a line without taintured chastity when amatory passion is causative of procreation out of wedlock.

The certainty of heredity in its primary form, causing an environment for the succeeding generation, is well established, and "it is a general biologic law that the lower the position of an animal in the scale of being, the greater its capacity for the reproduction of its kind."[3] "Hereditary tainture existing in an environment of its kind, is procreated through succeeding generations in the case of bastardy to an astonishing degree," as is graphically shown in the tables of Spitzga[4] and of Dugdale.[5]

The term "accidentals" is here used advisedly and for convenience, there being no English word to distinguish—in contrast to the woman who professionally sells herself—the one who lapses through imprudence, ignorance or passion, and afterward recovers and leads a reputable life. To this class is assigned all women of good heredity, good environment and heretofore unquestioned chastity, who yielded to temptation from causes that were immediate and seemingly insuperable.

Illegitimacy in its generic sense is an inadequate term, referring specifically to the state of being born out of lawful wedlock. In this paper the term is used to designate a vice, in which is the implication of a child, a mother, a father, the relatives, friends and community. It is the purpose of social economics to apply principles to problems connected with the growth and well-being of organized society.

It is the intent of this study to submit statistics and other material which can be used for inductive and deductive reasoning toward the formulation of applied principles for a subject which can be said to have substantially a very meager literature and comparatively few investigators. The difficulties that confront the student of illegitimacy are evident to all who have given the subject but little attention.

The general rules[6] of method in composing any discourse require, first, that nothing should be wanting or redundant; second, that the separate parts should agree with each other; third, that nothing should be treated unless it is suitable to the subject or purpose; fourth, that the separate parts should be connected by suitable transitions.

It is impossible to exclude the evidence of statistics in a scientific study of illegitimacy, and it is impossible to include them for all geographical divisions. There are in the United States 53 states and territories (including the Hawaiian Islands and Alaska). Of this number, 39 have state boards of health. Letters of inquiry for statistics relative to illegitimate births were sent to every secretary. Replies were received from 25 of the 39; 19 replied that there were no statistics taken. Many do not have any record of births, while some do not keep even death records.

Six states—Connecticut, Minnesota, Rhode Island, North Dakota, Indiana and Michigan—have records. In every instance the figures were affirmed by the secretaries to be unreliable, therefore of little value excepting for yearly comparisons of state averages. The secretary of state for Michigan, Hon. Fred M. Warner, estimates that probably only about two-thirds of the total number of actual births are being returned. In Michigan, during 1900, only 322 illegitimate births were recorded, the total of all births being 43,699. I was able to collect with little effort from seven sources 466 illegitimate births for 1903 in the city of Detroit.

Eight letters were sent to the registrars general of provinces in the Dominion of Canada, and six replies were received, Ontario being the only province that kept records.

I am indebted, as are all who find interest in the statistics submitted below, to the deputy registrar general of Ontario, and the adequate system of record taking that prevails in this province.

TABLE I.

Total of all births for 1902	47,796
Total of illegitimate births for 1902	819
Total of illegitimate births, male, for 1902	418
Total of illegitimate births, females, for 1902	401
Ratio of illegitimate births per 1,000 of all births	17.1
Ratio of illegitimate births per 1,000 of all births in 14 cities	50.9
Ratio of illegitimate births per 1,000 of all births in country alone	.13

TABLE II.

The four counties having the highest illegitimate birth rate compared, showing the city and the country ratios:

York County—	
Country ratio	23.9 to 1,000
City of Toronto	53.5 to 1,000
Carleton County—	
Country ratio	6.1 to 1,000
City of Ottawa	104.7 to 1,000
Middlesex County—	
Country ratio	6.5 to 1,000
City of London	50.7 to 1,000
Frontenac County—	
Country ratio	10.9 to 1,000
City of Kingston	59.4 to 1,000

TABLE III.

A comparison of the illegitimate birth rates, cities in England, Ontario and Scotland:

London, England, in 1889	38.0 per 1,000
Birmingham, England, in 1889	45.0 per 1,000
Liverpool, England, in 1889	58.0 per 1,000
London, Ontario, in 1902	50.7 per 1,000
Toronto, Ontario, in 1902	53.5 per 1,000
Kingston, Ontario, in 1902	59.4 per 1,000
Ottawa, Ontario in 1902	104.7 per 1,000
Glasgow, Scotland in 1887	83.0 per 1,000
Edinburgh, Scotland in 1887	85.0 per 1,000
Dundee, Scotland, in 1887	104.0 per 1,000
Aberdeen, Scotland, in 1887	106.0 per 1,000

The second rule of method is observed in deduction only, and the remaining rules are observed as closely as is consistent with the peculiar nature of the subject.

The economic problem before the practitioner of medicine, philanthropic worker and sociologist is that of prevention and cure of this macula of unchastity. For the purpose of securing unbiased premises, available literature was consulted, and thirty letters were addressed to experienced workers in widely distributed parts of the country, asking for answers to the following questions. The references and replies, as far as possible, are used, and credit given for the same in the subjoined bibliography:

1. What do you consider the chief causative factors of illegitimacy?

2. What practical preventative measures would you suggest for illegitimacy?

3. In the treatment of illegitimacy as a sociologic evil, would you advise the utmost personal secrecy of the individuals involved?

4. What is the best care of the bastard child for the economy of society, considering first the child, second the mother, third the father, fourth the relatives, friends and local community?

5. Is the lying-in hospital that extends care especially to illegitimate mothers a means of encouragement for the crime? (b) Are such institutions prophylactic against homicide, infanticide and suicide?

6. To what extent can the physician act as a safeguard to society in cases of illegitimacy?

7. In your experience, what percentage of illegitimate mothers are restored to their former position in society? (b) And what percentage go on to greater degradation?

The chief causative factors of illegitimacy are:

1. Insufficient instruction in the phenomena of sexual life, particularly of girls.[7 8 9 10 11 12]

2. "Incontinence on the part of the male, combined with the passive submission of the woman," with mutual passion prevailing.[13 7 14]

3. Faulty guardianship.[8 16 14]

4. Seduction under promise of marriage.[15]

5. "Lack of means to establish a home" and other impediments to marriage.[11]

6. The general servility of women and aversion to marriage on the part of males, and a prevailing notion that hard work is disgraceful and that good clothes are a necessity.

7. The remoter causes of heredity and environment have been proven to be important considerations[16 17 18]

8. *Conclusion.*—Leffingwell[16] has tersely summarized the causes in the following: "Illegitimacy is a phase of social phenomena produced by conjoint action of several causes. Its variance in the different localities depends on the force and number of the factors there present."

Pertinent to the subject are the words of Shakespeare: "Find out the cause of this effect, or rather say the cause of this defect. For this effect defective comes by cause."[19]

The aforegoing enumeration of causes alone suggest inferential preventative measures, which are tersely expressed by Professor C. R. Henderson[20] as "all the positive educational, moral, religious agencies which raise ideals, teach young girls their nature, dangers and duties, and give them a rational way of spending their leisure." To this must be added "early marriage" for the passionate.[21 22 15]

Leffingwell[23] says: "The influence of religion is one of the most powerful agencies against unchastity," and Dr. Howard A. Kelly affirms that the "Christian standard is the solution of the whole problem" of unchastity, as is expressed in the quotation: "Mortify, therefore, your members which are on the earth; fornication, uncleanness, inordinate affection, evil concupiscence and covetousness, which is idolatry, for which things' sake the wrath of God cometh on the children of disobedience."

All these excellent preventative measures must fail, and do fail, as statistics prove, for want of direct and specific application in much the same way as the physician does who prescribes water to stop hemorrhage, without informing the ignorant regarding the necessary tem-

perature, mode of application, etc., or the text-book of medicine that dismisses the treatment of a disease after stating that opium is indicated. The merest tyro in medicine or in social economy knows the value of the remedies in a general way. But this is probably parallel knowledge of that possessed by the man who says—I know opium relieves pain.

Is it not enough to say to the boy or girl—here is the moral law, hear it, read it, obey it, for it is the best advice in all phases of your life? The sexual nature must be plainly outlined by personal interview and confidences secured. Now is the time when profoundest wisdom and most careful judgment is demanded. The prophylactic suggestions must be given with the utmost care, and control taught through the specific means which is most directly applicable.

The question of utmost personal secrecy of the individuals involved admits of discussion. The answers received show that 75 per cent. favor secrecy. The following are among the reasons assigned: (*a*) Secrecy at this time is dealing with the fruits and not the root of the evil.[7] (*b*) Publicity causes loss of self-respect, and thus removes the chief bar to prostitution. It also serves to advertise the woman before men as susceptible material for extended liberties.[15] (*c*) These unfortunates have no chance in life with public opinion against them, for the disposition of society is relentless and unforgiving. (*d*) The return to society is made a personal responsibility with the mother when her secrets are preserved.[10] (*e*) The bastard is made to wear a lifetime label, which has the weight of personal guilt, and friends to whom not even hereditary implication can be imputed are disgraced, and "Good name, in man and woman . . . is the immediate jewel of their souls."[24] (*f*) Publicity is frequently the most active goad to the acts of abortion, suicide and infanticide. It is said[25] that "in order to lessen the frequency of abortion and remove some of its temptations, regulations prevail in some of the large lying-in hospitals of Germany, whereby each patient is known only by a number given her on entering, a duplicate of which is written on a sealed envelope in which she has inclosed her name, the address of friends, or any item she may choose. This is returned to her unopened on her departure from the hospital without mishap. The child is taken with her, or may remain in a ward of the state at her option."

Among the reasons given for publicity are the following: (*a*) The fear of publicity is a wholesome safeguard as far as the young man is concerned. The young woman should tell her parents, if they are people of any character, for the reason that if she does not do that she must lie from first to last, and you can not build character on a lie.[8] (*b*) Evils thrive in the dark.[14] The arguments for and against publicity are significantly strong, and it is evident that neither absolute secrecy, as is practiced in some of the German hospitals, nor the full publicity which is given the legitimate birth, can be best for all concerned. The following conclusions are drawn: The question of secrecy should be subservient, first, to the best interests of the child. It is the one most wronged, and should receive every advantage of all possible reparation. It is a human soul, and must outweigh all other results of the illicit act, such as the personal disgrace and the insult and injury to society. To society the mother is a unit of depreciated values, and is thereby the second most important result of illegitimacy. The best care of the child and mother is the best care for every phase of the problem.

In the event, then, of publicity serving the means of justice for child and mother by compelling the father to do his duty, whatever this may be, under the circumstances, secrecy would here be an injustice. The laws of Illinois[26] provide that the father may be compelled, if able, to make provision up to the sum of $550.

When a woman's parents are deceased or are individuals without character, or when it can be learned that they would cast off their erring child, and when the father of the child is a worthless wretch, absolute secrecy should be imperative. The resident of the rural district, town or small city will require secrecy more than the resident of the large city.

I believe most emphatically that the causes of illegitimacy should be published widely, and all possible emphasis placed thereon; but in the great majority of instances the results should be kept a profound secret.

The best care of the illegitimate child is that by its parents, providing they become man and wife. If practicable, every just means should be used to bring about this union. Of the answers received, 94.3 per cent. advise adoption into childless homes in from one to twelve months after birth; 75 per cent. urge adoption when the child is about one month old. Prof. C. R. Henderson of Chicago University[20] forcibly says: "Foundling asylums, baby farms and agencies which take babies from their mother's breast, and ask no questions, are murderers wholesale." This statement may seem unwarranted and altogether too radical, but on examination of certain records a mortality of 98 per cent. was shown. Leffingwell[27] affirms that in civilized England illegitimate bastard children are more than four times as liable to "accidents" as their legitimate kindred, and the same writer quotes the registrar general, who pointed out that during the first year of life the mortality of legitimate children was about 205 per 1,000, while the illegitimate rate was 418 per 1,000.

A most interesting field of investigation is suggested to me, viz., that of the milk supply from the breasts of illegitimate mothers. The following tentative theories are advanced on evidence thus far examined. The lacteal secretion of the illegitimate mother is markedly uncertain. The quantity is lessened and the quality impoverished. A number were found to have almost total cessation of secretion before the first three months were past. The supposition advanced is that involuntary nursing is a leading cause, supplemented by the disturbed mental tranquility. It is observed that abscess of the breast during the nursing period in this class of mothers is almost unknown. If a tentative conclusion can be made and proved, it will show that the illegitimate mother is incapable, physically, in the majority of instances. When there is added to this financial and social difficulties, the situation is well-nigh impossible. There is also a great probability that the illegitimate child, when old enough to be taunted about his disgraceful birth, will promptly despise his mother. The continuance of the illegitimate child in an environment parallel to its heredity is usually a grievous error, as shown by Dugdale[28] in his study of the Jukes. Of 535 children born, 106 were illegitimate, a ratio of 235 per 1,000. The members of the family that changed their environment at a sufficiently early period were able in most instances to amend hereditary habits.

[27] Leffingwell: Illegitimacy, pp. 70 and 73.

[28] Dugdale: The Jukes, p. 26.

The conclusion is drawn that the best care of such a child is adoption within one year, or better, one to three months, into a childless family, which has been investigated by a government agent, and by a responsible representative of the child.

The care that is best for the child is, as a rule, best for the mother, the father, relatives, friends and community. The early adoption of the child affords the mother every opportunity for restoration to her former place in society, providing secrecy has been maintained. She is thus able to obtain opportunities for marriage that would be impossible excepting with the lowest of men, were the sign of her fall with her. I have a record of eleven women, nine of whom are living in Detroit and two in the country. All of these are honorable wives and good mothers. All but one informed the prospective husband of her former misfortune, and in each case the man expressed himself as glad that the woman did not deceive. The one woman who did not confide her secret is in great fear of it being revealed. It is very true in this application that "hope deferred maketh the heart sick." If a woman in the sorest trial of her life can entertain no hope for her future, the liability to greater degradation is very certain.

Sanger,[20] in his "History of Prostitution," says that 57 of every 100 children born by women who are now prostitutes, were fruit of promiscuous intercourse, and that one-half of the prostitutes of New York City have given birth to children, and more than one-half of these are illegitimate.

The committee of the New York State Senate,[20] appointed to investigate prostitution, reported in 1892 that there were 50,000 prostitutes in New York City. Of this number some 12,500 had given birth to illegitimate children. These facts and figures indicate most pathetically the inefficiency of the method used by society for the care and restoration of its unfortunate illegitimates.

It is a frequently heard accusation that lying-in hospitals encourage crime. If such institutions are agencies for houses of prostitution, or if the management is by unprincipled and immoral individuals, the reputation is justly given. But the idea that honestly managed lying-in hospitals are causative of this evil is preposterous. It is just as logical to say the physician who cares for an illegitimate mother during her confinement is encouraging the evil by his professional care of its result, not of its cause.

Dr. Joseph B. De Lee[7] says the argument is ridiculous, and asks the question, Does the general surgical hospital increase the number of street brawls with cracked heads?

The contemplation of a child, much less that of a hospital, never enters the minds of the child's parents at the time of their fall. It is always an afterthought.

It is one of the highest privileges of the lying-in hospital to be the means of prevention for infanticide, suicide and homicide. An average of 50 per cent. of all applicants solicit abortion or have attempted the same.[15] The physician, more than any other public servant, is the guardian of the sexual morals of the communtiy.[26]

Each physician should consider it his privilege and duty to carefully study the social economics of illegitimacy, so that he can act intelligently in giving advice that is protective to life and society.

The percentage of restorations will depend to a large degree on the class of girls. Dr. Charles Pike[11] and Adjutant E. Bailey[10] estimate that 90 per cent. of all cases where it is a first offense are restored under proper treatment, while about 5 per cent. pass on to a greater degradation.

831 Fort Street, W.

ENORMOUS MIXED TUMOR OF THE PAROTID REGION

REACHING TO THE CLAVICLE AND WEIGHING ABOUT SEVEN POUNDS; OPERATION; RECOVERY.*

W. W. KEEN, M.D., LL.D.

Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College.

PHILADELPHIA.

The Patient.—E. M. B., aged 65, was admitted to the Jefferson Medical College Hospital, Jan. 2, 1904, at the request of Dr. H. M. Righter. Height 5.7 feet, present weight 152 pounds weight in 1890, 250 pounds.

History.—His father died at 49 of "dropsy of the brain"; his mother at 56 from pulmonary tuberculosis. One sister also died of the same disease and another after some gynecologic operation; one brother died from accident; one sister is living and well. Tuberculosis exists both in his father's and in his mother's families, but he does not know the precise individuals who have suffered from it. He is married and has five children, all of whom are living. He had varioloid when he was 22 years old. He has suffered from hemorrhoids and from neuralgia of the face. He was discharged from the Army in 1863 on account of "dropsy of the kidney." He drinks beer moderately; smokes a pipe almost constantly.

Development of the Tumor.—In November 1880, when shaving, he noticed a small lump in the right parotid region. It did not cause him any pain, nor was it tender at first. By 1883 the tumor was large enough to attract the attention of others. By 1892 it had grown to the size of a large walnut. At this time it was manipulated considerably by a physician, and from this he dates its rapid growth. He states that it has doubled in size during the last two years; has never noticed any effect on the flow of saliva. On Dec. 7, 1903, at the inferior border, the tumor opened and there was a forcible discharge of a fluid containing blood. He states that it broke with such force as to cause a hissing sound at first. About two pints of fluid escaped. For two years he has not left his house on account of the annoyance he experiences from everybody's looking at him.

Examination.—On admission there is noticed on the right side of the face and neck an irregular nodular tumor (Figs. 1 and 2) starting just in front of the ear, passing over the lower jaw, under the chin, and extending about 5 cm. to the left of the median line. It extends a little below the level of the clavicle and passes up the back of the neck not far from the median line. The circumference of the tumor horizontally is 63 cm. and vertically 67 cm. The horizontal diameter is 21 cm. and the vertical diameter 27 cm. The present size of the tumor, when the photographs were taken, is markedly less than it was before it broke.

The tumor does not seem to be deeply attached to the larynx or to any of the bones in its neighborhood, the jaw, the mastoid, or the transverse processes of the vertebræ. It is most firmly attached in the parotid region, but below this it can be swung through a considerable arc in all directions. The skin is movable over the tumor; its blood vessels are dilated, and its surface is rough, and at points ulcerated. At the lower border is an opening about the size of a lead pencil. Considerable fluid discharge constantly escapes from this opening. The fluid is brownish yellow, thin and watery. The tumor is composed of nodular masses of greater or less size, many of the larger ones have smaller nodules arising from them. They are elastic, yet firm. Portions of the tumor are evidently cystic; others

---

20. Sanger: History of Prostitution, p. 676 and addenda.

* Read before the College of Physicians of Philadelphia.

are either fibrous or cartilaginous. There are certain areas of tenderness over it. He has rarely had any pain excepting when it was distended by fluid before its rupture. The tumor is very heavy and drags on the face and neck so much that both for support and also to retain dressings over the sinus at the lower portion, he slings it by a bandage over his head.

Examination of the Body Fluids.—The urine is of amber color, turbid in appearance, specific gravity 1,026; acid reaction, urea 2.6 per cent. By the microscope a few squamous and columnar epithelial cells and a few leucocytes are found.

Examination of the blood showed hemoglobin 78 per cent., erythrocytes 4,830,000, leucocytes 7,800, color index 0.81.

The examination by Dr. Stelwagon of 55 c.c. of the fluid discharged from the tumor showed it to be a cloudy, yellowish-pink fluid which, on standing, separated into two distinct layers, an upper clear and a lower cloudy stratum. The reaction was neutral to both litmus and phenolphthalein, specific gravity 1,008, that of the normal saliva being 1,002 to 1,006. Sulphocyanid is absent. It is highly albuminous as shown by Tanret's reagent, heat and nitric acid. There was also a small amount of mucinoid substance. A very faint trace of the nitrites was present. Neither sugar nor other reducing agent was found either in the solution or the sediment. The specimen was tested for the presence of ptyalin or other amylolytic enzymes by the admixture of the solution with soluble starch; the resulting mixture was then digested for one hour at 40 C. and tested. The test for erythrodextrin and sugar proved negative. Microscopic examination showed the sediment to consist of many polymorphonuclear leucocytes and a few erythrocytes; no epithelium nor salivary elements were found.

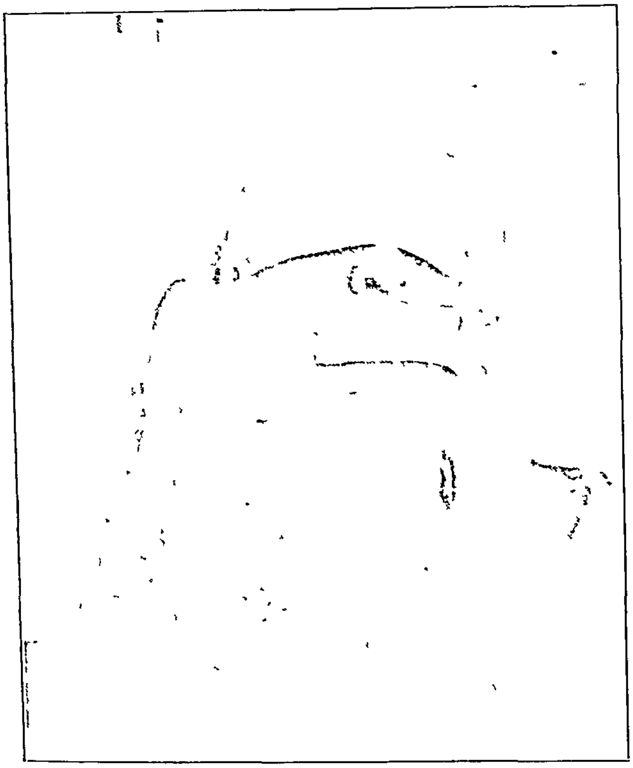

Fig. 1.—Tumor seen from the front

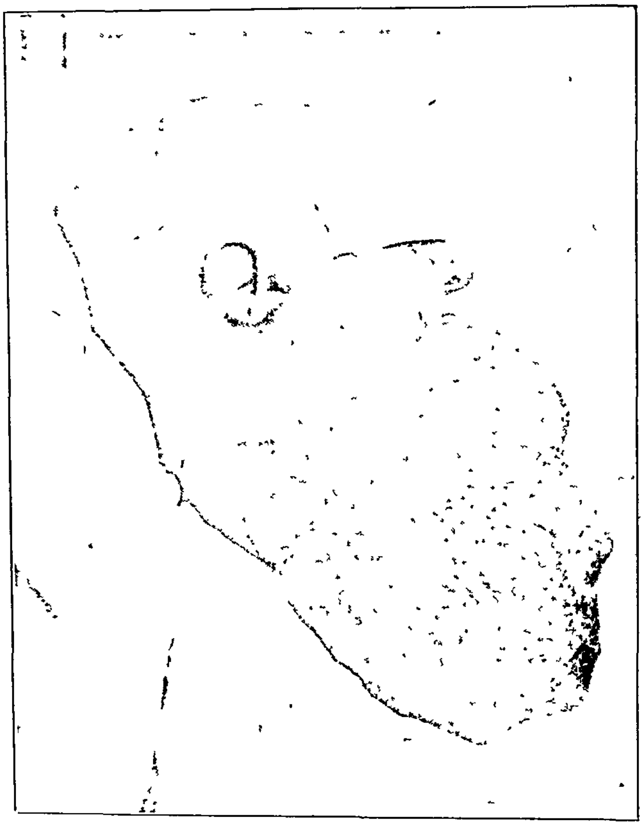

Fig. 2.—Tumor seen from the side.

Operation.—Jan. 6, 1904. Drs. Hearn and Stewart, together with the house surgeon, Dr. Gillette, kindly assisted me. I first made an incision from the ear to the collar bone, a little internal to its vertical axis, thus passing over the tumor in such a direction as to give me a considerable anterior flap. This was dissected from the front and the inner side of the tumor; then dragging the tumor outward with retractors, I was able gradually to separate it from all the deeper tissues of the neck, including the jugular vein and carotid artery. The tumor was very adherent to the vessels, the sterno cleido mastoid and the auricularis magnus; a number of branches of the facial were unavoidably divided, though I did not recognize any of them. A number of large veins emptying into the jugular were found on the surface of the tumor. Each one of these was double ligated and divided. By the weight of the tumor the submaxillary gland was drawn down over the anterior surface of the tumor to the level of the upper border of the thyroid cartilage. This was dissected off the tumor and the facial artery, which passed through it, was double ligated and divided. I then formed a posterior flap of skin similar to the anterior and finally removed the entire tumor. At probably a dozen or fifteen places the fascia between the lobules was spread out in dense fibrous layers, which had to be divided one after another, the division of each one enabling me to roll the tumor outward with greater ease. In the parotid region, in dissecting it out, a moderate amount of the parotid gland was removed. As there was considerable oozing over the entire surface, I placed two layers of iodoform gauze on the surface, inside of this two layers of plain sterile gauze, and closed the entire wound, leaving gauze protruding at lower end.

During the operation he was given four pints of salt solution and two drams of adrenalin (1 to 1,000) gradually administered. The operation lasted an hour and ten minutes.

Blood Pressure.—The blood pressure the day before the operation by the Riva-Rocci apparatus, was 164. mm. When the etherization was begun the blood pressure was 210 mm. It rose within ten minutes to 230, but when the first incision was made it fell to 205. At the same time the pulse, which before etherization stood at 80, gradually rose during the etherization to 125, where it stood at the time of the first incision. The blood pressure rose slightly after the operation was begun and then, as it was continued, fell to 185 at the end of the first half hour. The infusion of adrenalin and salt solution was then begun and the observations on the blood pressure necessarily were interrupted by this procedure, as it was necessary to use the left arm for both these observations and the infusion, since I was standing on the right side, and could not allow the right arm to be used. After the operation the pulse remained at the same level, 125, but the blood pressure had fallen to 110 mm.

Convalescence.—His highest temperature after the operation only reached once a little above 99 until one week after the operation, when it rose once to 101. The cause for this was perfectly clear. The incision was close to the corner of the mouth on the right side. The operation necessarily paralyzed the seventh nerve, which was involved in the tumor, and in consequence of this, there was a constant dribbling of saliva. This produced a slight infection at the middle of the wound, and delayed the final healing for a considerable time. Other than this he made a perfectly smooth recovery.

Examination of the Tumor.—At the time of the operation, a culture was taken from the discharge through the open sinus. Prof. W. M. L. Coplin reported that after 48 hours a pure culture of *Staphylococcus pyogenes albus* was present. Specimen (Fig. 3) shows the tumor and the large cavity in the center. The size of the tumor was 25 cm. long and 17.5 cm. in diameter. The weight was 2,440 grams, over 4¾ pounds, to which, before the rupture, should be added over two pounds of liquid, which escaped, making the tumor originally about seven pounds in weight. I give the remainder of the report by Professor Coplin and Dr. Ellis in full:

Gross Anatomy.—"A long incision which has been made into the specimen, on the surface opposite the area of skin, shows it to contain an enormous cavity that forms a large part of the bulk of the mass, the tissues described being in the form of a shell that varies from 1 to 8 cm. in thickness. The cavity is entirely devoid of contents. The limiting wall is grey in color, with pinkish markings, and is made exceedingly rough by projecting ridges of tissue. These ridges traverse the wall in every direction, and are from 1 to 3 cm. in width at their bases, narrowing outward until in many instances they become very thin at their most prominent parts. Owing to the curvature of the wall of the cavity the external margins of two of these ridges are, in some sites, brought in close proximity, the spaces between them leading into pocket-like recesses which closely approach the external surface of the specimen. The ridges are formed of tissue similar to that making up the exterior of the mass. The incised surfaces are grey in color and have a cartilage-like consistency. At several points the density of bone is almost or quite attained.

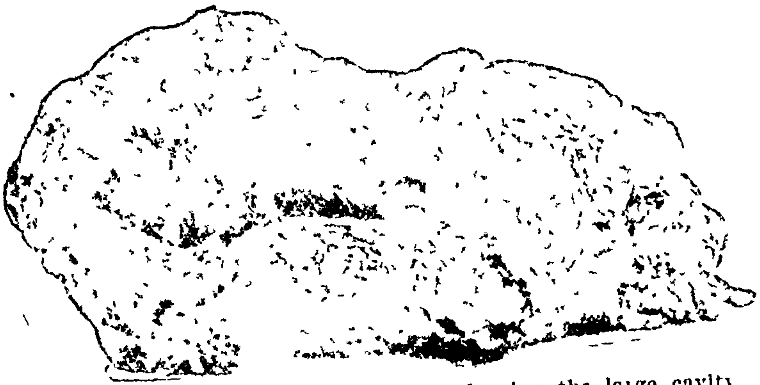

Fig. 3.—The tumor after removal, showing the large cavity.

Microscopic Examination.—"Small portions of the specimen were fixed in Bensley's and Zenker's fluids and in 10 per cent. formalin. The gross specimen was preserved in Kaiserling. Blocks of tissue from the former were dehydrated, cleared and infiltrated with celloidin. Sections from these blocks were stained with hematoxylin plus eosin of Van Gieson, toluidin blue, thionin, Mallory's reticulum stain, and Weigert's stain for elastic tissue.

"Histologic study of the sections shows them to be composed of very diverse structures. Those including a part of the external surface of the tumor show a thick fibrous capsule. The external portion throughout, and at some points nearly the entire substance of this capsule is extremely dense and practically a vascular fibrous tissue. The inner portion is less dense, contains distinct blood vessels, and in some areas is quite cellular in type. At certain points are small areas of adipose tissue, adjoining which are variously shaped small open spaces in the dense outer portion of the capsule that appear to be included fat Within the capsule are areas of the tumor composed of cells within a matrix of either fibrous or myxomatous tissue or areas of cartilage. The cells are mainly round or oval, with here and there a few that are spindle shaped. In some areas they form distinct masses, with but scanty intercellular substance, while in others they line spaces, presumably lymph spaces, being here from one to many layers thick. As previously stated, the supporting structure in some of these areas is fibrous tissue, which in some instances forms distinct trabeculæ. In other areas the matrix is myxomatous In certain of these areas the cells are numerous, forming quite distinct masses; in others they are comparatively scanty, being arranged in narrow bands that cross each other in such a way as to give a distinct plexiform appearance. Here the cells are oval or flattened in shape and the nuclei stain poorly, contrasting markedly with the masses of larger, round, deeply staining cells, which in many instances are separated from them only by a moderately wide band of fibrous tissue. The former present the appearance of true sarcoma cells, and have among them numerous thin-walled blood vessels, while the latter are undoubtedly derived from the endothelial lining of the spaces which they enclose.

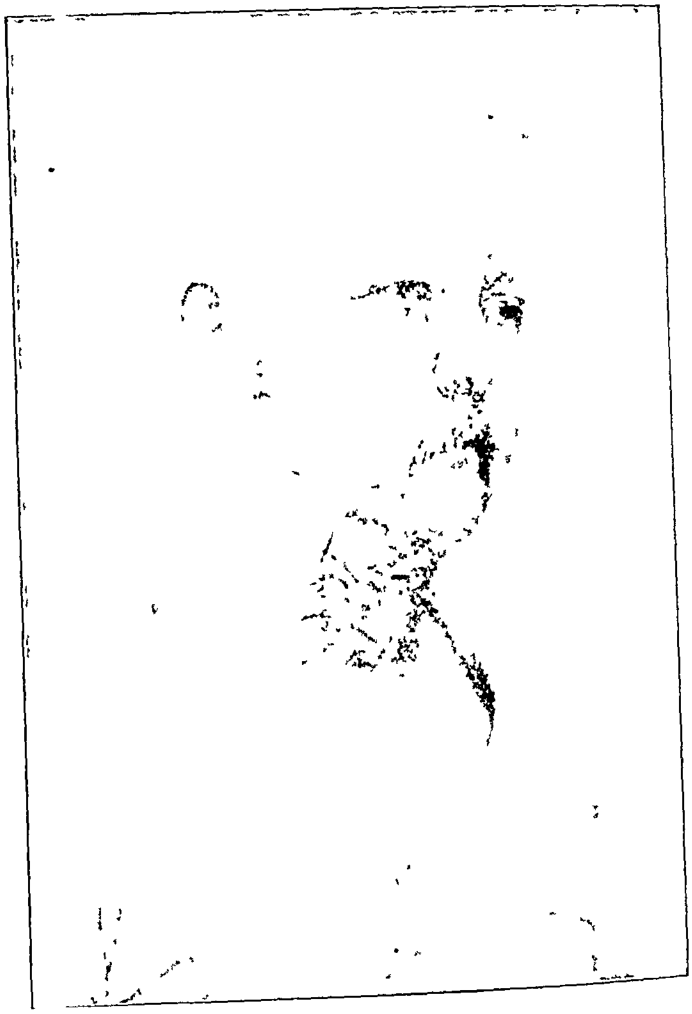

Fig. 4.—The patient three months after operation.

"Many of the sections are composed partially, in some instances almost wholly, of cartilage. This is usually fibrous in type, though areas of the hyaline variety are to be noted. The capsules of many of the cartilage cells are wrinkled and contracted. In a few areas bone formation has been attempted as shown by the presence of osteoid tissue containing lacunæ and distinct cells, but lacking true lamellæ. At some points the stroma between masses of the tumor cells has undergone hyaline change, giving such areas a very close resemblance to the so-called cylindromas.

"Sections which include the inner surface of the tumor, the wall of the large cavity, show it to be bordered by softened, fragmented and slightly necrotic tumor tissue. A few polymorphonuclear leucocytes are also present.

"Sections stained for elastic tissue show an abundance of that structure in the stroma of the tumor, especially in the less dense areas where the cells are least numerous.

"Sections stained by carbol-thionin show in some areas an exceedingly fine network that stains a distinct reddish tinge.

"*Diagnosis.* — Myxo-chondro-lymphangio-endothelioma. Although no salivary gland structure has been found in the sections studied, the specimen conforms in every particular to the mixed tumors which occasionally originate in those organs, particularly the parotid."

REMARKS.

The diagnosis and structure of these mixed tumors of the parotid region have been so thoroughly considered by Dr. O. A. J. Kelly[1] and Francis Carter Wood,[2] that I do not consider it necessary to consider them here anew, as I could add nothing of importance.

From the surgical point of view, the slow and later the rapid growth, the enormous size (certainly the largest tumor of the neck I have ever operated on), his age and the fact that I was able to dissect it away from the important structures, especially the blood vessels of the neck, and the very happy recovery of the patient, justify the report of such a case.

I may add that not only is he well, but, having been practically imprisoned in his house for over two years by reason of his annoyance when people observed him, he now once more freely goes out and mingles with his fellow-creatures. The operation has given him a new lease of life. The only price that he pays for it is a long visible scar and paralysis of the right seventh nerve, a small price for such a delightful relief. Figure 4 shows the result three months after operation.

Clinical Report.

REMOVAL OF PIN FROM LUNG PER VIAS NATURALES.

WITH BRONCHOSCOPE AND TUBE FORCEPS.*

E. FLETCHER INGALS, M.D.

CHICAGO.

History—A young woman suffering from a foreign body in the lung was referred to me, March 23, by Professor Senn. She stated that nearly a year ago she had drawn a large glass-headed pin into the trachea, and that it had caused severe cough, expectoration, and at times choking spells and pain. About six weeks ago Dr. Allison of Brownwood, Texas, had done tracheotomy, but as it was impossible to find the pin he had closed the wound, which had healed quickly. A radiograph taken at the Presbyterian Hospital located the pin, head downward in one of the divisions of the right bronchus.

Operation.—I operated the next day, assisted by Drs. G. H. Kennett, A. M. Corwin, O. T. Freer and N. P. Colwell. I first administered gr. 1/60 of atropin hypodermically to check secretion, then gave chloroform, and when anesthesia was nearly complete, sprayed the larynx and trachea once with a solution of cocain, 10 per cent., and suprarenalin 1 to 4,000 guarded by atropin, strophanthin, carbolic acid and oil of cloves as in the solution I use for anesthetizing the nares. I then introduced a Killian bronchoscope, 34 cm. in length and 8 mm. internal diameter, through the larynx down into the right main bronchus, and one of its larger branches. The parts were illuminated with a small (Chicago Electro-Appliance Co.'s) No. 1 (cold) lamp with carrier 33 cm. in length, that I had made for the special purpose. The secretions and a very little blood were repeatedly swabbed out with cotton and the parts touched with the same solution of cocain. I carefully explored the three branches of the bronchus, and with a blunt hooklet searched for the pin which I did not succeed in bringing into view for about three-quarters of an hour.

Finally, with the hooklet, I brought it across the end of the tube and demonstrated it to Professor Senn and to E. J. Senn, S. A. Friedberg, J. F. Dolamore, E. L. Kenyon, to my assistants, and to several other physicians who were present. I then caught it with Killian's tube forceps and tried to bring the end of it into the bronchoscope but although I released it several times and manipulated it in various directions, I could not succeed, therefore, I finally grasped it firmly and drew it and the bronchoscope out together. In doing so the pin was bent to an acute angle near the head, and that it caused some injury to the parts was evidenced by a little soreness the next day, but this disappeared in a few hours. There was a temperature of about one degree two or three hours after the operation, but no fever subsequently. Three days later she returned to her home in Texas.

The pin was of brass, 4 cm. long and the glass head measured 5.5 by 8 mm. in diameter. It was apparently lodged in a division of the bronchus passing downward and backward, but I was unable to see the head at all, and could see nothing of the pin itself until I swept it across the end of the tube with the blunt hooklet.

New Appliance.

AN ARMY SPLINT.

HOWARD W. BEAL, M.D.

Late Assistant Surgeon U. S. Army.

WORCESTER, MASS.

During an army service of three years, including transport, field and hospital duty in the Philippines, the need of a leg splint that could be used for emergencies in the field, as well as for fixed dressings in the hospital, was often seen, and it was to supply this need that the splint here described was devised. When I was assigned to the surgical service of the First Reserve Hospital in Manila, the base hospital of the Philippines, the leg-splints on hand were inadequate to supply the hundred surgical patients, as there was no efficient leg-splint obtainable for general field or hospital use, and for any immobilization it was necessary to improvise with straight splint and plaster, a slow and unsatisfactory method.

THE CABOT SPLINT.

The splint is a modification of Dr. A. T. Cabot's posterior wire leg-splint which has been in use at the Massachusetts General Hospital in Boston for the past twenty years. The Cabot splint (Fig. 1) is made of a round, wrought-iron rod, three-eighths of an inch in diameter, shaped into a long rectangular frame, extending from the fold of the buttock to an inch beyond the heel, where it turns at a right angle, making a foot-piece, twelve inches long. The cross-piece, at the fold of the buttock, is slightly curved to the line of the thigh, and completes a rigid frame which, when padded, supports the leg. In the hospital the various lengths required are kept prepared for immediate use.

An important advantage of the splint emphasized by Dr. Cabot is its use in cases of discharging sinuses of the leg or thigh. In these cases, the cross-winding near the wound is omitted, and the rod is covered with a waterproof protection, as oil silk, which permits the wound to be dressed without disturbing the immobilization.

THE ARMY SPLINT.

The modification of the Cabot splint for army service consists in folding the foot-piece on the leg rods, and arranging the leg rods and thigh cross-piece to allow extension. (Fig. 2.) A rivet hinge is placed at the junction of the foot-piece and leg rods, and to secure firmness, the rods of the foot-piece are carried up one inch inside the leg rods, where the ends are flattened in outward curves to clasp tightly the under half of the leg rods. (Fig. 3.)

The leg extension is obtained by two closely approximated square rods, each having at its end a rectangular collar closely fitting the accompanying rod. (Fig. 4.) The extension of the cross-thigh piece (Fig. 5), which is slightly curved to fit the back of the thigh, is secured in the same way as the leg rods, but with flattened collars. The leg rods are so adjusted that opening the cross-thigh extension (Fig. 5, B) releases the leg rods so they will slide to any desired length, and closing the cross-thigh extension (Fig. 5, A) locks both the cross-thigh and leg extensions at any point.

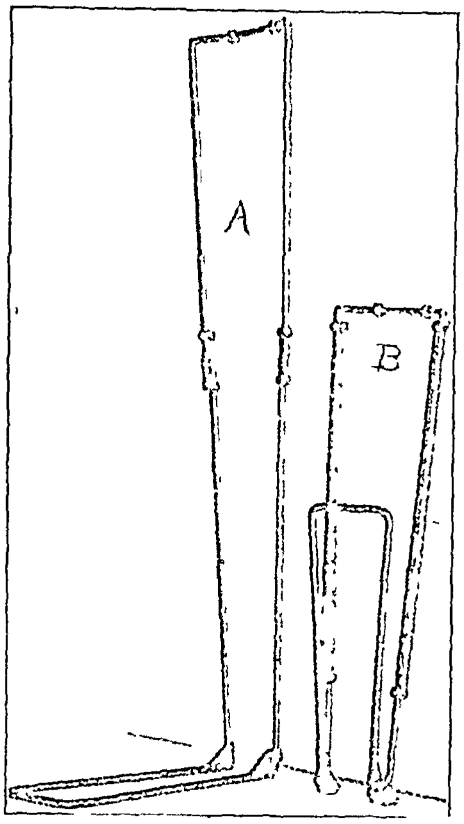

Fig. 2.

Fig. 1.—The Cabot posterior wire splint
Fig 2.—The Army splint.. A. Extended B. Closed.

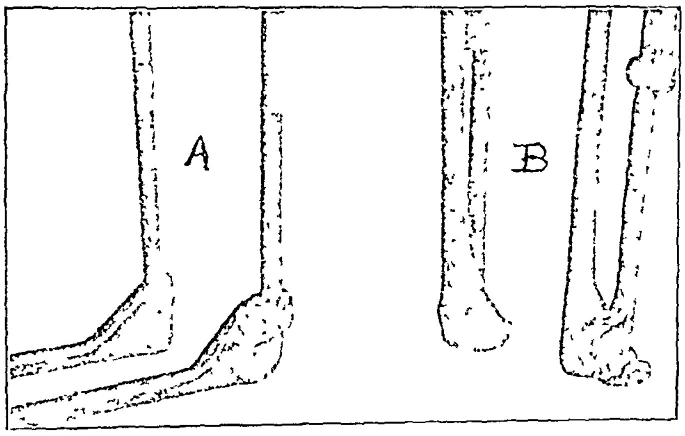

Fig. 3—Showing detail of mechanism at junction of foot-piece and leg rods. A. Extended. B. Closed.

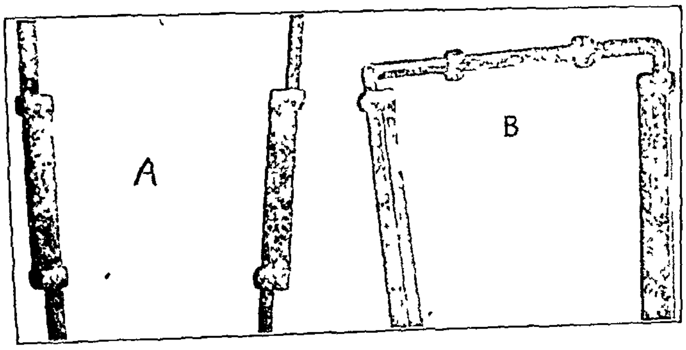

Fig. 4.—Showing leg rods. A. Extended. B. Closed

The splint folded is twenty inches in length and weighs three and a half pounds. It occupies little space and can be easily transported, two points of vital importance for the military surgeon in the field.

For use as a field or emergency splint, the foot-piece is unfolded, the cross-thigh extension opened, the leg rods extended to the desired length, and the cross-thigh extension closed to lock the leg extension. A blanket is folded to the length of the leg and foot-piece (Figs. 6 and 7), and on this the leg and foot are fastened to the splint with bandages, or any straps available

PADDING THE SPLINT FOR HOSPITAL USE.

For hospital use, the splint is prepared as is the Cabot splint, by first winding the rods spirally with a narrow band of cotton "sheet wadding" (Fig. 8, A) then cross-winding the entire frame with bandage to make the bed of the splint (Figs. 8, B, and 12, A). On this bandage bed is placed a thick pad made of four or five pieces of sheet wadding folded to the shape of the splint, and extending from the cross-thigh piece to the ankle. (Fig. 9.) A small additional pad is placed between the layers to fill the popliteal space (Fig. 9, BB), and the whole padding held on the frame by four or five pieces of tape or narrow bandage. (Fig. 9, CCCC.)

The foot-pad is made by covering heavy pasteboard (which has been cut to fit the foot-piece) with sheet wadding an inch thick,

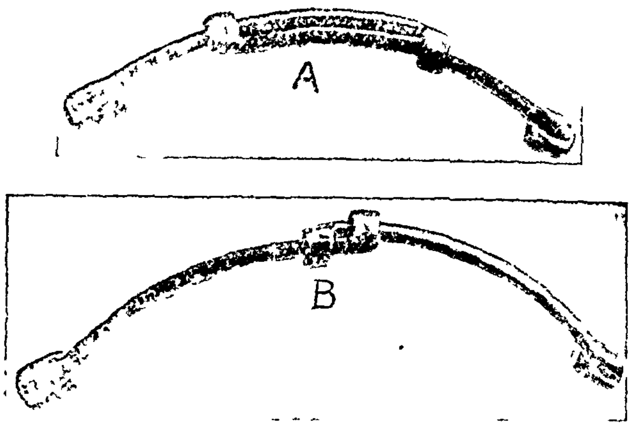

Fig. 5—Cross-thigh piece. A. Closed to lock itself and leg rods B. Opened to allow leg rods to slide to desired length

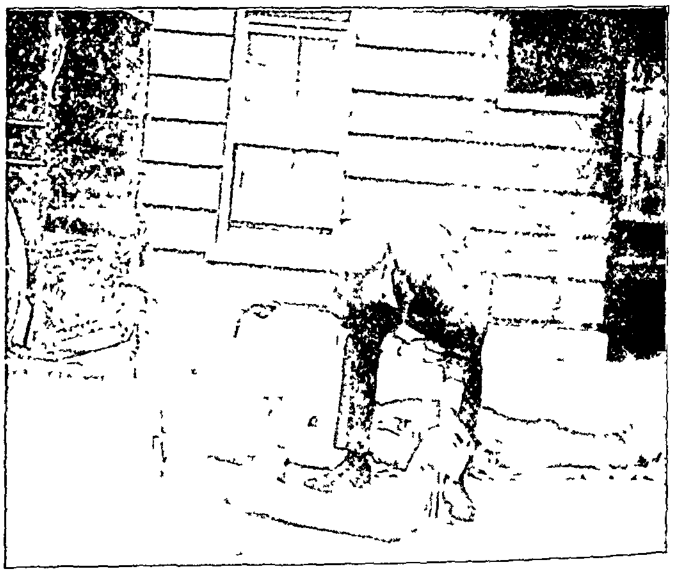

Fig 6—Showing method of preparation for field or emergency use with folded blanket.

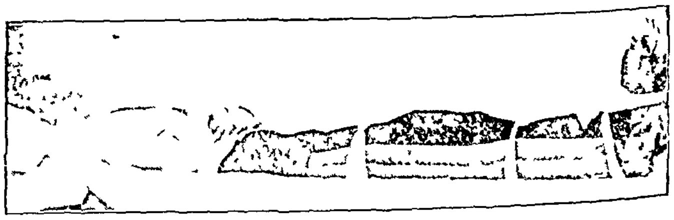

Fig. 7.—Showing field or emergency use with blanket—completed

with an outer cover of muslin, and fastening this around inner edge of bandage-covered foot-frame, with pins. (Fig. 9, AA).

On this padded splint, the leg is held by straps of adhesive plaster (Fig. 10), the heel occupying the vacant space between the foot-piece and the padding at the ankle. The leg is then wound with a layer of sheet wadding torn in strips, five or six inches wide, rolled, and applied spirally. (Fig 11, A.) The leg is now bandaged from the toes to thigh. (Fig. 11, B).

This is sufficient for ordinary immobilization of the leg, but in case of fracture, three "side-splints" are added, to maintain the position of the reduced fragments. The "side-splints" (Fig. 12, BB) are pieces of straight board, four inches wide, one-fourth of an inch thick, and one inch longer than the splint, padded on the inner sides with a thin layer of sheet wadding and covered with muslin. One of these is placed under the bandaged leg between the leg rods of the splint; the other two are placed on the sides of the leg, and the inner sides padded by enclosing folded towels in half sheets or pillow cases, folded to fit the lateral contour of the leg, to maintain the lateral position of the fragments. These side-splints are held on by four strong straps made of cotton webbing, one and one quarter inches wide. (Figs. 12, E, and 13).

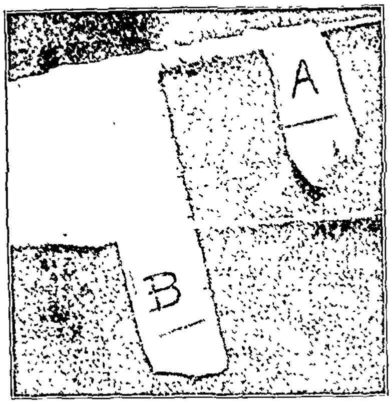

Fig. 8.—Showing method of preparation for hospital use. A. Winding rods with strip of cotton sheet-wadding. B. Cross winding rods with bandage.

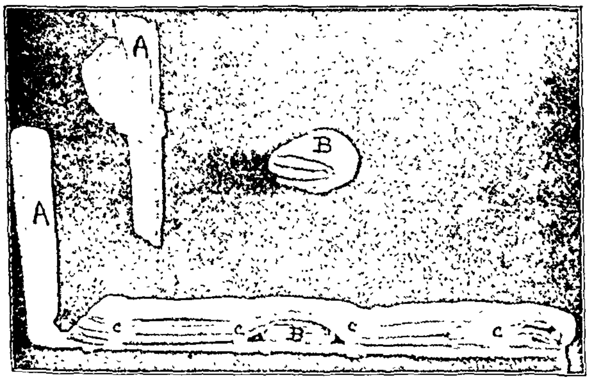

Fig. 9.—Showing sheet-wadding padding. A A. Foot-piece pad. B B. Popliteal pad. C C C C. Narrow bandage or tape holding padding to splint.

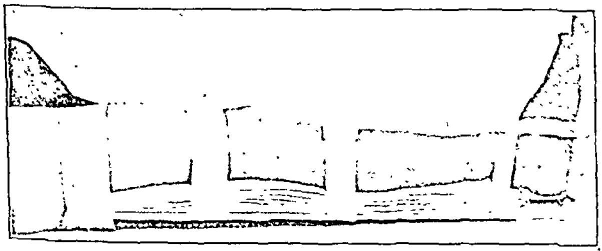

Fig. 10.—Showing leg held on splint by adhesive straps with pad under strap at tubercle of tibia.

ADVANTAGES.

1. The splint will fit any leg, thus avoiding the necessity of making several splints of different lengths.

2. Its simplicity, lightness and compactness make it valuable for all conditions of army field and hospital service.

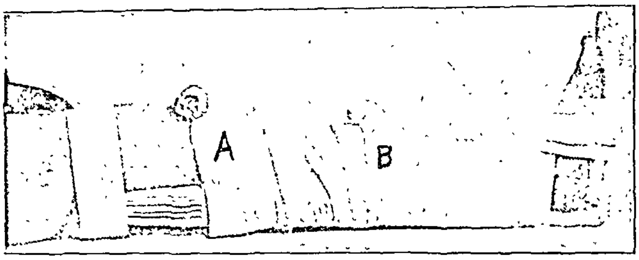

Fig. 11.—Showing method of winding and bandaging the strapped leg. A. Cotton roll of sheet-wadding. B. Bandage.

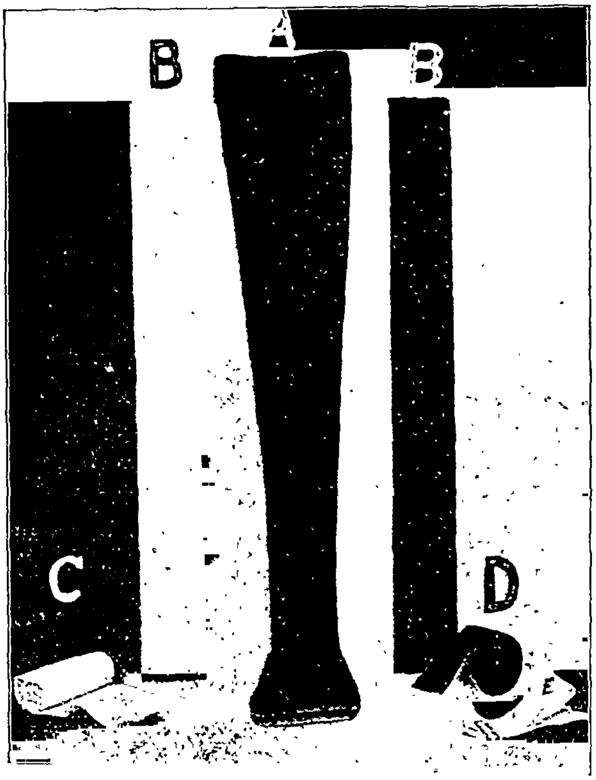

Fig. 12.—A. Splint wound with bandage. B B. Side splints for use with fractures. C. Cotton roller. D. Folded bandage. E. Cotton webbing strap to hold side-splints.

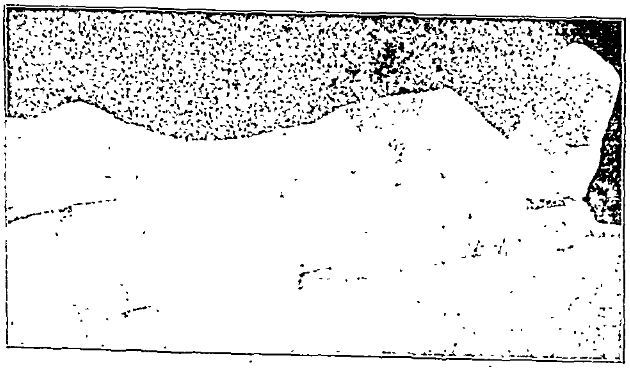

Fig. 13.—Showing side-splints applied for fracture.

3. The Hospital Corps of the Army can be taught its field use, with its preparation and use for hospital cases, thus establishing a uniform and efficient method of immobilizing every kind of leg injury.

THE ATLANTIC CITY SESSION.

Considerable space in this issue is taken up with matter relating especially to Atlantic City and to the coming session of the American Medical Association, including the programs of the sections. The promise for a large meeting is greater than for any previous year. The fact that the railroad rates are so favorable will certainly encourage many to attend who would not otherwise think of doing so. Never before has the Association had better than one and one-third rates when meeting in the territory of the Trunk Line Association. This year, however, the rates are one fare for the round trip, plus $1.00, which will make the traveling expenses, even for those who have to go a long distance, comparatively low.

In the matter of hotels, no place offers better inducements than Atlantic City. Those who desire to economize will find good hotels at moderate prices, and those who want to live on the best can find accommodations—and prices in proportion.

Atlantic City is a popular resort, both in winter and in summer, but the climate in June is all that could be desired. The time is also a good one, for the reason that it is between seasons, and the pleasure resorters will not be there—to any great extent at least. The fact that the place of session is so close to the thickly settled part of our country and to the principal medical centers, will naturally favor a larger attendance than would otherwise be the case.

At the session held in Atlantic City four years ago 2,019 were registered, and last year at New Orleans 1,993 were registered. If such a large attendance could be had at a place so far from the majority of the members as New Orleans, we may expect at least 50 per cent. more at Atlantic City this year, on account of the nearness to the center of population, the splendid hotel accommodations, and other advantages.

We print the programs of eleven of the twelve sections, and a cursory reading of these will convince anyone that the scientific work alone ought to stimulate many to attend. Each section offers most excellent scientific work, and there is much to attract not only the ultrascientific man and the specialist, but the general practitioner also.

The local profession has worked hard to make the session a success, and we do not doubt that those who go only for pleasure will be well satisfied with the entertainment that will be accorded them.

The section meeting places are more compactly located than they were four years ago, and consequently "that tired feeling," that was complained of at Atlantic City before, on account of so much walking in going from one section to another, will be avoided.

Altogether the outlook for the session is unusually bright. The stimulus of the organization movement which has swept over the country, and the features of Atlantic City, which we have mentioned above—all these will combine to make the fifty-fifth session one of unusual interest.

THE N RAYS.

We recently spoke of the discovery of the remarkable N rays and commented on their sources. The properties of the rays have been determined sufficiently so that the rays may be properly classified. They are reflected from polished surfaces, such as glass, and are also refracted, as is shown by the fact that they can be focused by means of a quartz lens. It should be stated that several foci may be obtained in this way, indicating that there are rays of different wave lengths. The index of refraction was found by Blondlot to vary from 1.04 to 1.85. Wave-length determinations vary from 0.008 μ to 0.018 μ. They are, therefore, rays of very short wave lengths, and the above measurements place them in the spectrum far out beyond the ultraviolet. The rays can be polarized, differing essentially from x-rays.

The penetrability of these rays is remarkable. They pass through plates of tin, copper, brass, aluminum, steel, silver, glass, mica, paraffin, fluorin, sulphur and wood. They are arrested by lead, rock salt, platinum and water. A salt solution is very permeable. A piece of cigarette paper when dry or moistened with salt solution is easily penetrated, but when moistened with water is quite opaque to the rays. Certain substances seem to have the power of absorbing the rays and giving them out later. The Leclanche cell has already been mentioned. Hyposulphite of soda has been found to possess this property after exposure, for example, to the light from a Nernst lamp. Sea water emits the rays for a time after exposure to the sun. An interesting fact in connection with these rays is the property which they possess of being transmitted by a metal wire. Only those metals transmit the rays in this manner which are penetrated by the rays. They have been transmitted a distance of 10 meters. It is necessary for the surface of the wire to be smooth or polished in order to conduct the rays; if the surface is oxidized it no longer conducts them. Therefore, the property of reflection may be the determining factor here, as pointed out by Bichat, the process being analogous to the phenomenon of the conduction of light through a piece of curved glass by the principle of successive reflection.

The N rays do not have any effect on a photographic plate directly. However, the effect which they exert on a luminous source, as a small electric spark or a flame, can be recorded by means of photography, and Blondlot[1] shows some very clear pictures illustrating this. Very recently he has observed rays which have a shorter wave length, and which, instead of increasing the luminosity, decreases the luminosity of a phosphorescent screen. These rays he has called N_1. They are emitted by compressed caoutchouc, celloidin and ivory, pieces of silver iodid and ice near the temperature of zero. These rays diminish the sense of smell, vision and hearing, thus apparently acting in an opposite manner from the N rays.

Interesting application has already been made of the physiologic facts observed concerning N rays. Ballet has studied the emission of these rays in certain pathologic conditions. He found that in myopathies, neuritis and acute anterior poliomyelitis there was a noticeable decrease in the emission of these rays along the course of the nerves as compared with the normal emission. In hemiplegias and spastic paraplegias the emission of rays is increased. In diseases, therefore, involving the lower neurons there is a diminution, and in those involving the upper neurons there is an increase in the emission of rays from the peripheral nerves. Thus there seems to be an exact correspondence between the emission of rays and the activity of the neuron. Charpentier claims that he could detect rhythmical alterations, corresponding to inspiration and expiration, in the phosphorescent screen when placed over the respiratory centers low down in the occipital region.

Naturally many have been skeptical concerning the observations made by the Nancy physicists, and have called into question certain phases of their work. Swinton,[2] while not absolutely denying the existence of the rays, is strongly inclined to think that many of the observed phenomena are due to heat rays, and has performed some experiments to prove this. Charpentier gives what seems to be very conclusive evidence that the N rays are entirely different from heat rays. For example, the contraction of the muscles of a frog's leg, which may even be below the temperature of the screen and the room, furnishes the rays in abundance. He also made careful determinations of heat effects with the electric pile, and comes to the conclusion that the heat rays are not responsible for the increased luminosity observed in the screen. Walscham and Miller[3] and also Hooker,[4] in England, have confirmed the work of the French, and agree with them perfectly regarding the fundamental facts. Work in the *Lancet* laboratory has also confirmed these observations. The evidence in favor of these rays is accumulating so rapidly and is at present so convincing that their existence can hardly be called into question.

IRON THERAPY.

The history of the employment of iron in therapeutics is most interesting, and is full of lessons in drug application and their supposed effects. Iron has been used empirically so far back as any definite knowledge of medicine goes. Its medical uses are mentioned by Pliny, who evidently recognized definite indications for its employment. It was employed long before it was known that iron existed in definite quantities in the body, and that the affections in which iron seemed to do good were really those in which there was a marked diminution of the normal amount of iron. There seem to be some grounds for believing that the reason why iron was employed at first was no better than the primitive notion that anemic individuals were weak, and that somehow iron out of its strength supplied them with renewal of vigor.

Therapeutics have been enriched by really efficacious remedies in much more modern times without any better reason than this. The fact is that Sydenham's expression, "To the worn out and languid blood, iron gives a spur or fillip whereby the animal spirits, which before lay prostrate or sunk under their own weight, are roused and excited," is as good a basis for the use of iron in medicine now as it was in his day. We must confess that we do not know how it acts, and that even now the rationale depends rather on our knowledge of its clinical value than on all the supposed reasons for its efficaciousness, which have supposedly been furnished by physiologic therapeutics. It remains an empiric and not a rational remedy. It is sometimes the custom to think that it is belittling to use remedies for which we have only empiric reasons, and Sir William Gowers was not far off when he recently said: "I yield to no one in my sense of the importance of the rational in therapeutics, but we need to be careful lest, in contrasting the rational and empirical, we allow our esteem for the one to induce a depreciation of the other."

There was a time, and that not very long since, when there was almost universal consensus among authorities in therapeutics that iron was an example of the use of a specific in medicine. Then came a period in which it was considered to be rather a nutrient in the sense that it supplied a deficiency in the tissues, than as a remedy in any true sense of the word. At the present time there are many good authorities on therapeutics who do not hesitate to say that iron acts, not by supplying the place of the lacking hemoglobin, but rather by its stimulating effect on digestive and absorptive processes in the intestines. There are even those who have insisted that the use of iron when it was actually absorbed in any considerable amounts brought about a degeneration, or at least degenerative appearances in the red blood corpuscles, not unlike those which are seen in certain phases of lead poisoning.

Of the advantage of the employment of iron in certain cases there can be no doubt. This has been recognized by clinical experience, even when it is administered in very crude forms. There are country people still alive who remember when their fathers went to the village store, bought half a pound of shingle nails and a quart of vinegar, and having allowed the nails to remain in the vinegar for some time, gave the resulting solution containing some acetate of iron to their anemic wives, or more especially chlorotic daughters, and thought they obtained good results. In the midst of the present discussion of organic preparations of iron as the only possible iron compounds that can do good, and to the application of the most delicate tests in order to show that iron compounds can possibly be efficient in the human economy, this old-fashioned form of iron therapy must seem woefully crude, yet it would seem that it was often wonderfully effective. On the other hand, it must not be forgotten that one of the most distinguished English clinical authorities of modern times, Sir Andrew Clark, insisted that chlorotic forms of anemia particularly were due to constipation more than to anything else, and could be very successfully treated by proper attention to this symptom rather than by the direct treatment of the lack of hemoglobin.

THE EXAMINATION OF SCHOOL CHILDREN'S EYES AND EARS.

Since the publication of Beer's treatise on "Healthy and Weak Eyes" in 1800, in which many useful and important hints are given to teachers regarding the preservation of the sight of their pupils, physicians have appealed to the public conscience for a regular examination of school children. It is not, therefore, due to a lack of knowledge that these defects in our otherwise admirable public-school system have received so little attention, but because, until quite recently, there has been no systematic and sustained effort to introduce some simple, effective and practical means of detecting ocular and aural diseases that is capable of ready application by the teachers themselves. Appeals for the proper care of children's eyes and ears have borne better fruit in continental countries—especially in north Germany—than in the United States, chiefly because a paternal form of government seems more fit for the promulgation of widespread reforms of this character than does our own, where the work has to be carried on mostly by private enterprise or by agitations repeated in and for each state. However, the labors of such pioneers as Dr. Peter Callan (who in New York thirty years ago demonstrated the existence of eye defects in a large percentage of school children), of H. Derby, Mittendorf, Randall, Risley, Cohn and others, have served as a basis for a ready method of examination which has already been adopted by many school boards.

In a paper read this month before the International Congress of School Hygiene at Nuremberg, Professor Cohn of Breslau called attention to this subject, and referred to the fact that forty years ago he inspected the Breslau school children, which is perhaps the first systematic work done in this line. Until then school hygiene had hardly been thought of. From 1864 to 1866 he examined the eyes of over ten thousand children in search of the cause of the then recognized increasing short sight.

From his investigation he concluded that the number of shortsighted children steadily increases with the development of the school, *from the lowest infant department* through the high school, that myopia increases from class to class; in other words, that it is produced by school life. His experience during the past ten years has also proven to him that the acuity of vision in young children in the open air is two or three times greater than that of children in the school room. He has for years advocated the appointment of ophthalmologists for the examination of school children, and although much has been done in this regard, the number of shortsighted students has not diminished.

In 1895 Dr. Frank Allport, in a paper on "Refraction in Schools,"[1] advocated a plan for instructing teachers how to examine pupils above the first grade for the detection of eye defects. Later he added simple tests for aural affections, and finally perfected a scheme whereby instructions for the examination of school children's eyes and ears, for the use of principals and teachers, are combined with a vision chart. Provided with these ready means of examination even a novice may establish (or disprove) a probable disease of a pupil's eye or ear in a few minutes.

Briefly described, the apparatus consists of a Snellen test chart, appropriately mounted, with directions for the examination of the vision of each eye separately. This reading test shows the amount of defect, if any, in the pupil's eyesight. Then follow nine "facts to be ascertained,"[2] which throw further light on the subject, and serve to detect the more important diseases of the eye, nose and throat.

The plan has already received wide acceptance. Many state societies, among which are those of Michigan, Delaware, Minnesota, Colorado and New York, have adopted resolutions and appointed committees on the subject. The state boards of education of Texas, Kansas and Minnesota have approved the scheme and have put it in practical operation, as have the state boards of health of North Dakota, Illinois, Montana, New York, Indiana, Connecticut (where it is operative under a state law), Minnesota, Kansas, Colorado and Ohio. The American Public Health Association, as well as the Conference of State and Provincial Boards of Health of North America, has also recommended its general adoption. It may also be added that the government schools of India have recently adopted this plan of examination.

---

[1] THE JOURNAL A. M. A., March 2, 1895.

[2] These are: 1. Does the pupil habitually suffer from inflamed lids or eyes? 2. Does the pupil fail to read a majority of the letters in the number XX (20) line of the Snellen test types, with either eye? 3. Do the eyes and head habitually grow weary and painful after study? 4. Does the pupil appear to be "cross-eyed"? 5. Does the pupil complain of earache in either ear? 6. Does matter (pus) or a foul odor proceed from either ear? 7. Does the pupil fail to hear an ordinary voice at twenty feet in a quiet room? Each ear should be tested by having the pupil hold his hand over first one ear and then the other. The pupil should close his eyes during the test. 8. Is the pupil frequently subject to "colds in the head" and discharge from the nose and throat? 9. Is the pupil a habitual "mouth breather"?

If an affirmative answer is found to any of these questions the pupil is given a printed card of warning to be handed to the parent. These cards are non-obligatory in their nature. They do not require anything of the parent, who is at perfect liberty to take notice of the warning card or not, as he sees fit. If the parent neglects the warning it is repeated.

We would suggest to those state societies that are yet to meet this year and to all county societies to take up this subject, and not only pass resolutions, but also appoint committees to make the work more effective, uniform and general throughout the country. A uniform plan for the examination of pupils' eyes that can be used by teachers should be adopted after thorough consideration. If the scheme referred to above is not satisfactory, another and better one should be devised. This is really a work that belongs to state medicine as much as to ophthalmology, and consequently a committee representing both the Section on Ophthalmology and the Section on Hygiene and Sanitary Science, would seem to be advisable, the functions of this committee being not only to formulate a perfect plan, but also to enter into correspondence with the state superintendents of schools and others interested relative to having the plan adopted all over the country.

If experience should demonstrate that the plan of having teachers examine the eyes of their pupils does not prove satisfactory, then we should adopt the motto of Cohn, "Keine Schule ohne Augenarzt."

CLINICAL DIAGNOSIS OF LESIONS OF THE PANCREAS.

The importance of the pancreatic functions in the maintenance of health is now universally recognized, and in consequence, the pathologic conditions affecting the gland are being more thoroughly investigated and their clinical effects more keenly studied and appreciated. The symposium on "The Pancreas and Pancreatic Diseases," at the last Congress of American Physicians and Surgeons,[1] epitomized the general knowledge of the subject, and if little addition was made to its extent the more glaring defects were strikingly emphasized. It was demonstrated that various abnormal conditions affecting the ducts and the parenchyma of the pancreas were usually productive of rather indefinite signs and symptoms, and which were, moreover, frequently difficult of differentiation from those resulting from pathologic processes involving neighboring structures. Certain lesions (e. g., acute pancreatitis, chronic obstruction of the common bile and pancreatic ducts) usually give positive indications for the institution of procedures that will almost certainly lead ultimately to the proper diagnosis and treatment, but there are many conditions that do not give these indications, and in which the proper treatment is of but little if any less consequence, so that any feasible and accurate diagnostic aid in the determination of the presence and nature of pancreatic lesions would be of the greatest value. Particularly is this true since it has been conclusively demonstrated that some operations, although performed for the relief of other conditions, have proved to be so beneficial to certain not uncommon pancreatic lesions.

The recent reports of Mayo Robson[2] and Cammidge[3] record the discovery of an apparently accurate and fairly simple clinical test capable not only of indicating the existence of a pancreatic lesion, but also, in a way, of determining its nature. Mr. Robson's reputation carries conviction that the method is worthy of general adoption. It has been fully described in The Journal.[4]

Cammidge's experiments, as reported, seem to exclude the possibility of error or of faulty interpretation of the results. Both are to be congratulated on so important a contribution to clinical methods, especially Mr. Cammidge for the able deduction of the chemical reaction. Whether this may prove to be as efficient in the hands of other laboratory workers, remains to be demonstrated. There is no apparent reason why it should not, and with the large amount of material to be found in hospitals, there should be widespread investigation, and, let us hope, confirmation of such valuable and important observations.

THE GERMAN YELLOW-FEVER EXPEDITION.

We recently referred in our news columns to the fact that not long ago the Institute for Ship and Tropical Diseases in Hamburg sent a fully equipped expedition to South America to study yellow fever in particular. The results already obtained by American, English and French observers will now be subjected to thorough tests, and further reports from the expedition will be awaited with much interest. We see in expeditions of this kind the strongest evidence of the great interest now felt in tropical diseases and hygiene. This movement seems to date back only a few years. The epochal discoveries of Patrick Manson and Ronald Ross were followed by the establishment in Liverpool of a school for tropical medicine by means of funds contributed by wide-awake and philanthropic business men. This school has sent out several investigative expeditions, the results of which have been important in the fight against malaria, and more recently in clearing up the etiology of sleeping sickness. In addition, this school gives courses in tropical medicine. Other seaports have followed the example of Liverpool, and similar institutions have been started in London, Hamburg, Bordeaux and elsewhere for teaching and research, location in seaport towns being necessary in order to gain access to the proper clinical material. The German expedition, which also is to study and report on sanitary conditions in South American harbors, is supported financially by the merchants of Hamburg. Whether viewed from the philanthropic or commercial point of view, the study of tropical diseases and maritime sanitation is so important that we can only rejoice because it is fast becoming a matter of international competition. It may not be out of order to ask what is being done in this field in the great seaports of the United States, in addition to guarding against the importation of infectious diseases. So far as we know there is now no place in America where a physician may receive special instruction of the proper kind in tropical diseases and allied subjects. We look for the establishment of an institution of this kind in Manila before long, but it is quite evident that there is room and need for one or more such institutes in the United States proper.

SANITARY IMPROVEMENT IN SLEEPING CARS.

It is announced in the lay papers that the Pullman company has adopted a new design for sleeping cars, which is intended to more nearly meet the sanitary requirements. There will be no elaborate grill work, and the surfaces will be curved as far as possible. Material has been selected for the curtains and seat coverings which can be easily cleaned and disinfected. It is also stated that orders have been issued for more thorough disinfection of cars in which sick persons have traveled. Nothing more unsanitary in a case of infectious disease can well be imagined than the present upholstering of the Pullman railway cars, and the reform is one that certainly will be indorsed by the medical profession. The cars will gain the favor of the traveling public also, although much plainer in appearance and less luxurious than the older ones. It is hoped that the disinfecting and cleaning methods which are claimed to be practiced by the company will be thoroughly carried out.

REASONS FOR THE DECREASED BIRTH RATE.

A sociologic student, Mr. Robert Hunter, in a recent issue of the Chicago *Commons*, adopts the view that the decrease in the birth rate of the native American population is only the result of a universal law which was pointed out years ago by Farr, an English student of vital statistics. That authority observed that while emigration increases the birth rate of a country, immigration to a country almost invariably decreases its native birth rate, and at the same time increases the birth rate of the newly arrived immigrants. According to Gen. F. A. Walker, formerly superintendent of the Federal Census, this has been notably demonstrated in this country. In Mr. Hunter's opinion, immigration has not increased the population any more than would have been the natural increase had there been no immigration whatever. But by reducing the native birth rate it has prevented the propagation of a uniform and valuable stock to an extent that we all at the present time think to be undesirable. Of course, statements like these are not based on actual figures, or if so, the data are limited and have many lacunæ; still, such speculations have a certain probability, and there are other reasons why the truth of the theory should be accepted. These we need not here discuss. We have simply stated the explanation given of the reduced native birth rate, as a suggestion for thought.

EPIDEMIOLOGY OF PARATYPHOID FEVER.

Fischer describes in a recent article[1] an epidemic of paratyphoid fever which occurred in Kiel, affecting more than eighty persons, and which is especially interesting because of its probable origin. Without going into details, suffice it to say that on account of the distribution of the cases, it was relatively an easy matter to exclude water supply, milk supply and the character of the soil from having had any rôle in the spread of this epidemic. In one single house occurred nine cases (in practically all cases the diagnosis was established on the basis of the usual typhoidal symptoms of mild type—only one death—and by carefully controlled agglutination tests). In this house lived a butcher who had his shop in it, and these facts directed attention to the possibility that meat might have played some rôle in the spread of the disease. Inquiry brought the information that with five exceptions the families in which paratyphoid occurred were customers of this butcher. The exceptional cases Fischer would explain as the result of contact infection. He also points out that in an ordinary butcher shop conditions exist that in every way favor the secondary contamination of healthy meat by meat from an infected animal or infected in other ways. In this way he believes that the Kiel epidemic receives an explanation, which in every way harmonizes with all the facts in the case. Paratyphoid bacilli are more than usually resistant to heat. Thus heating for 30 m. to 60 degrees C. did not destroy the bacilli isolated from the cases in this epidemic. Even 5 m. to 75 degrees C. did not destroy all the bacilli. This resistance would serve to explain how imperfectly cooked infected meat, especially sausage, may spread this disease. While the evidence in Fischer's paper is not conclusive as to the nature of this epidemic, yet the facts brought forward are highly suggestive and instructive. It serves to focus attention on the butcher shop as a possible starting point of epidemics of typhoid-like diseases.

THE BRAIN AND SPINAL CORD IN HEREDITARY ATAXIA.

Some of the important clinical features of hereditary ataxia are summarized as follows by Sanger Brown:

> Hereditary ataxia is a disease which may be traced through several—at least four—generations, increasing in extent and intensity as it descends, tending to occur earlier in life and to advance more rapidly. It usually attacks several members of the same family. It occurs most frequently between the ages of sixteen and thirty-five, but it may begin as early as eleven and as late as forty-two. It shows no marked preference for sex, but it descends through females four times as frequently as through males. . . . There is always considerable inco-ordination of all the voluntary muscles, and a sluggishness of the movements they produce, when the disease is well advanced. This is usually noticed first in the muscles of the legs, but in a few months or years it extends. . . .

---

[1] Festschrift zum sechsigsten Geburtstage von Robert Koch, 1903, p. 271.

The anatomic changes in a disease so peculiar as this, with such remarkable hereditary tendencies, naturally arouse great interest. We now have recorded by Barker[1] full description of the brains and cords of two brothers (in the family studied by Sanger Brown) dead of this disease, and the following are some of the most important changes: In both cases the brains and cords were relatively small. Microscopically degenerations were found in gray and white matter of cord, medulla and cerebellum. The degeneration involved the cells and fibers of certain centripetal paths (dorsal nuclears of Clarke, direct cerebellar tract of Flechsig into the restiform body, and a system of exogenous fibers corresponding to the third fetal system of Trepinski, dental nucleus of cerebellum, inferior olivary nucleus of medulla oblongata). One other case of this same family has been studied histologically by Adolph Meyer with, in general, identical results. These reports make it clear that the morbid changes in the members affected in the family described by Sanger Brown, are quite constant, the same neuron systems being involved, but the next question, namely, why are these special systems picked out, medical science as yet can give no answer. The special reasons for referring to this subject in this way are, first, to call the attention of those especially interested to Barker's report, and, second, to emphasize the great value of co-operation to the end that rare and valuable material of this kind may be utilized to the fullest possible extent. The physician in the country and small town without facilities and time for the prolonged work necessary in order to do justice to much material that naturally comes his way, nevertheless may further directly the progress of medical science in this country by securing the co-operation in such cases of investigators with the force and equipment of well-organized laboratories behind them.

Medical News.

CALIFORNIA.

Siskiyou County to Have Hospital.—The supervisors of Siskiyou County have let the contract for a hospital to be erected at Yreka, at an expense of about $10,000.

Personal.—Dr. Rosa H. Engert, formerly of Chicago, was seriously injured in a street-car accident at Santa Barbara, April 10, sustaining a fracture of the skull.——Dr. Frederick T. Bond, has been elected secretary of the Vallejo Board of Health, and health officer.

Health Board Needs More Money.—The San Francisco Board of Health asks for an appropriation exceeding by more than $100,000 that of last year. The chief items of increase are: Emergency Hospital, $9,760; Leper Hospital, $590; Smallpox Hospital, $2,800; Almshouse, $7,100, and City and County Hospital, $80,750.

COLORADO.

March Deaths.—The total deaths for March numbered 837, equivalent to an annual death rate of 17.12 per 1,000. There were 24 deaths from diphtheria, 12 from typhoid fever, and 9 from scarlet fever.

New Home for Dependent Children.—The State Home for Dependent Children has just moved into its new buildings, erected at a cost of $60,000, at University Park, Denver. Admission to the home is made through the district courts, and the state becomes sole guardian. There are now 145 children in the institution.

Contagious Diseases.—The following cases of contagious disease were reported to the State Board of Health during March: Diphtheria, 148; scarlet fever, 128; smallpox, 78, and typhoid fever 39. Compared with February, March showed an increase of 63 cases of diphtheria, and a decrease of 3 cases of scarlet fever, 107 cases of smallpox, and 10 cases of typhoid fever.

DISTRICT OF COLUMBIA.

Physician is Military Secretary.—The President has signed the bill making Brigadier-General Frederick C. Ainsworth, M.D., military secretary, under the new law, with the rank of major general.

New Naval Hospital.—Surgeon-General Rixey has just returned from an inspection tour, the purpose of which was the location of a new naval hospital. He recommends that it be located at Charleston, S. C.

New Morgue Completed.—The new morgue building erected for the District of Columbia and located on the water front, has been completed by the contractors and is ready to be accepted by the district commissioners.

For Increase of Army Medical Corps.—Surgeon-General O'Reilly and Major Jefferson R. Kean recently appeared before the committee on military affairs of the house and urged the passage of the bill which provides for the increase in the medical corps of the Army, commensurate with the size of the army required by law.

Health of the District.—The report of the health office for the past week shows the total number of deaths to have been 111, of which 70 were white and 41 colored. There were 94 births, of which 73 were white and 21 colored. At the close of the week there were under treatment 9 cases of diphtheria, 27 of scarlet fever, and 52 of typhoid fever.

ILLINOIS.

Scarlet Fever in Evanston.—Evanston has 17 cases of scarlet fever under quarantine at present, most of the patients being children who attend the Dewey school.

Fake Doctors Fined.—"Drs." Wallace and Ferguson, itinerants, arrested at Pekin for practicing medicine without a license, pleaded guilty, April 11, and were each fined $100.

School for Feeble-Minded Children.—Beverly Farm Home and School for Nervous and Backward Children, Godfrey, has just completed a brick school and gymnasium building, which will greatly increase the resources of this institution and makes it more effective for good work.

Doctors as Delegates.—B. E. Garrison of Wayne County reports the names of physicians selected as delegates to the state Republican convention, from his county, as follows: Drs. Thomas J. Hilliard, Jeffersonville, Dr. G. A. McDonald, Golden Gate, and Dr. Barney E. Garrison, Wayne City.

Personal.—Capt. Carlton E. Starrett, Elgin, assistant surgeon, Ill. N. G., has been made major and surgeon, and assigned to the Third Infantry, vice Dr. Henry Richings, Rockford, promoted.——Dr. Dorwin D. Barr, Weldon, is ill with smallpox.——Dr. and Mrs. Elbert E. Clark and wife, Danville, have sailed for Europe.

Chicago.

Rejects Inspection Plan.—The school management committee of the Board of Education has rejected the plan of Trustee Hartung for a more rigid examination of school children.

Addition to Home Treasury.—As a result of the "Living Whist" game at the Auditorium, April 18, the Home for Convalescent Women and Children has added $2,000 to its treasury.

Pneumonia Mortality Still High.—The pneumonia mortality has already broken all April records. During the first 23 days of the month 403 deaths were reported—a daily average of 22.1. The April daily average for the previous fourteen years had been 12.4. For the current month the daily deaths from pneumonia have been 78 per cent. higher than usual.

College Elects Directors and Officers.—At a recent meeting of the stockholders of the Chicago Eye, Ear, Nose and Throat College the following directors were elected: Drs. William A. Fisher, Adolphus G. Wippern, H. W. Woodruff, Thomas Faith and John R. Hoffman. The directors thereupon elected Dr. William A. Fisher, president and treasurer; Dr. Adolphus G. Wippern, vice-president, and Dr. John R. Hoffman, secretary.

Males and Aged Die.—Of the total 643 deaths for the week ended April 23, nearly 58 per cent. were of males and 42 per cent. of females—the excess of the former being due, among other causes, to their greater exposure, and 24 per cent. of the deaths were among those over sixty years of age, whose vitality has been reduced by long confinement in over-heated and poorly ventilated rooms. The mortality was equivalent to an annual death rate of 17.37 per 1,000. Pneumonia leads with 141 deaths, or nearly 22 per cent., then follow consumption with 75, heart disease with 57, Bright's disease with 54 and violence with 39.

---

[1] The decennial publications of the University of Chicago, 1903, x.

IOWA.

Smallpox.—Seymour is said to be suffering from an epidemic. Public schools have been closed and 25 houses are under strict quarantine.

College Life Ends.—The sixty-third annual commencement exercises of the Keokuk Medical College were held, April 19, when 45 graduates received diplomas. Dr. William B. LaForce delivered the doctorate adddress.

Personal.—Dr. Joseph A. Valenta has been re-elected health officer of Iowa City.——Dr. Rastus B. Raessler, Anthon, was seriously injured in a runaway accident.——Dr. Adelaide L. Ainsworth, Fort Dodge, is seriously ill with typhoid fever.

Medical Library Association.—At a meeting of physicians of Council Bluffs a medical and library association was formed, with a view to the installment of a medical reference library in the new Carnegie library building. Dr. F. W. Dean was elected president.

MARYLAND.

Baltimore.

Injured in Runaway.—Dr. Hiram Woods was seriously injured internally by a runaway accident, April 22, in Druid Hill Park.

Student Kills Himself.—Mr. Ernest Money, a medical student of Baltimore Medical College, committed suicide by inhaling illuminating gas, April 21. His body was found in the bath tub. It is said it was due to despondency from fear of being unable to pass the Maryland State Examining Board.

Society Meeting.—The Medical and Chirurgical Faculty met for its 106th annual session, April 26, 27 and 28. The first evening was devoted to the adoption of the new constitution prepared by the committee, of which Dr. H. O. Reik was chairman. The antitoxins and the Röntgen rays were discussed. Clinics were held at the various hospitals. The president, Dr. Eugene F. Cordell, delivered an address on "The Importance of the Study of the History of Medicine," and Dr. John B. Deaver of Philadelphia delivered the annual oration entitled "The More Remote Consequences of Infected Bile." Dr. C. C. Bombaugh read a poem on "The Foes of the Household." On the last evening a banquet was given at the Hotel Stafford, Dr. R. W. Johnson being toastmaster.

MASSACHUSETTS.

Visiting Nurses in Cambridge.—Cambridge has organized a visiting nurses' association, and will raise a fund of $5,000, to be used for the salary of their nurses for the first year, and for fitting up a home for them. A house has already been secured.

Home for Cripples.—The Massachusetts Committee on Public Charitable Institutions has reported a bill providing for the appointment of a commission of three who shall expend $300,000 for the purchase of land and erection of buildings for a school and home for crippled and deformed persons.

Heavy Expense for Insane.—The report of the trustees of the Boston Insane Hospital shows that under the new state law, the expense of Boston for its insane poor will be largely increased. Formerly this expense amounted to $625,000 a year. This next year it will foot up $737,200. Under the new law the state assumes the care of all the insane, paying Boston $3.25 per week for the 600 now cared for in the Boston Insane Hospital, and leaving that institution in the care of its present trustees. The state tax, however, is very largely increased, amounting to $1,870,000 this year, and of this Boston must pay 36 per cent.

MICHIGAN.

Their Silver Wedding.—On April 23, Dr. and Mrs. Charles S. Cope, Ionia, celebrated the twenty-fifth anniversary of their marriage.

Senior Student Drowned.—M. J. Tinker, a senior student at the University of Michigan Medical Department, was drowned by the capsizing of a boat, April 20.

Radium Water and Sensational News.—A member of the faculty of the Medical Department of the University of Michigan asks us to publish the following notice, which it has been found necessary to have printed to send to those who have been deceived by the sensational newspaper items concerning the use of radium water. The notice is as follows: "The authorities of the University do not hold themselves responsible for the reports in circulation in the public press concerning the use of 'radium water,' so-called, in the treatment of cancer; and hereby notify patients not to come here in the expectation of receiving such treatment."

NEW YORK.

The epidemic of typhoid fever at Watertown is now completely under control. Since January 1 there have been 600 cases, of which 44 have proved fatal.

Smallpox.—During 1903 Jamestown had a limited epidemic of smallpox, with 174 cases, but without a death.——Many new cases of smallpox have been reported to the department of health of Buffalo.

To Allow Felons to Resume Practice.—A bill has been introduced to amend the act in relation to the qualifications of a person who may practice medicine. The law at present states that no person shall practice medicine who has ever been convicted of a felony by any court. The amendment reads: "But where the felony for which the person was convicted was not committed in the performance of his professional duties, and a pardon by the governor has been granted, such person may thereafter resume practice."

New York City.

Bellevue Internes Contract Phthisis.—Several physicians on the staff have been stricken with tuberculosis since the first of the year as a result of overwork and strain because of the overcrowded condition of this institution.

Health Fund Deficit.—Owing to the unusual prevalence of contagious diseases the health department has incurred a debt of $258,678, and Dr. Thomas Darlington has asked the board of estimate and apportionment to raise this amount by bond issue for immediate use.

Money Needed for Hospitals.—The collections fell off this year owing largely to a stormy Hospital Sunday, about $8,000, and the fund is about $4,000 short. The distributing committee has appealed for aid in making up this loss, as the city hospitals have never stood in greater need.

Dr. Morton's Widow Dies.—On April 21, Mrs. W. T. G. Morton, widow of the physician whose work with the anesthetic properties of ether brought it into prominence, died at her home in this city, from pneumonia, aged 79. An article by Dr. Morton appeared in The Journal, April 23, on the early use of ether.

Personal.—Dr. Edward L. Keyes, Sr., sailed, April 23, for Europe. He will join Dr. Lewis A. Stimson and they will take a two or three months' yachting trip along the Mediterranean. ——Dr. and Mrs. Charles T. Poore sailed for Europe, April 23, on the *Zeeland*.——Dr. Patrick H. Fitzhugh sailed for Europe, April 23, on the *Pretoria*.

Campaign Against Mosquitoes.—The board of health has opened its spring war against mosquitoes by issuing a statement requesting physicians to notify the departmentt of all cases of malarial fever which come under their observation; the surrounding locality will then be searched for breeding places and measures taken to kill the larvæ.

County Association Election.—At a meeting of New York County Medical Association, April 18, the following officers were elected for the ensuing year: President, Dr. Francis J. Quinlan; vice-presidents, Drs. Henry A. Dodin and S. Busby Allen; secretary, Dr. William R. Stone; corresponding secretary, Dr. John J. Nutt, and treasurer, Dr. Charles E. Denison.

Contagious Diseases.—For the week ended April 16. 1,416 cases of measles were reported, with 34 deaths; 481 cases of pulmonary tuberculosis, with 210 deaths, 466 cases of scarlet fever, with 28 deaths; 73 cases of varicella; 18 cases of whooping cough, with 8 deaths; 415 cases of diphtheria, with 56 deaths, and 16 cases of typhoid fever, with 6 deaths; there were also 410 deaths from pneumonia.

Physician Sues Estate.—An attempt to collect a check for $10,000 against the estate of an Albany millionaire by Dr. Harris Moak of Brooklyn is being tried before the Supreme Court. While a student he was employed as nurse and masseur to the deceased. About ten days after receiving a check, his patient died, and fourteen months later Dr. Moak presented this check to the executor, who alleged that it was void and fraudulent.

New Bellevue Hospital.—The designs for the new Bellevue Hospital have been made public. They call for a building which, exclusive of land, will cost $11,000,000, which will cover three city blocks and will be the largest hospital in the world, not only in floor space, but in the number of patients it will accommodate. The plans provide for thirteen pavilions under one-roof, but connected by arcades. There will be roof gardens for convalescents, and a water-cure department equipped with all modern apparatus for the hydropathic treatment of disease. There will be spacious quarters for 100 doctors, 100 male nurses, 200 women employes, and 350 male employes. The five upper floors of the south wing will contain medical wards, the limit of each ward being 25 patients. The five upper floors of the north wing will contain surgical wards. The surgical amphitheater will be equipped with 10 operating rooms, all within easy access to the various wards and complete in every detail. Beside the approval of the trustees of Bellevue and Allied hospitals and the board of estimate the plans will have to be submitted to the State Board of Charities, where, it is expected, considerable opposition will be encountered.

OHIO.

Personal.—Dr. and Mrs. William H. Manning, Dayton, have returned from a trip to Mexico and the south.——Dr. Hugo Maetke, Dayton, has returned after a stay of two years in Europe.——Dr. Charles W. King has been re-appointed health officer of Dayton.

Assistant Physicians Meet.—The third annual meeting of the Association of Assistant Physicians of the Ohio State Hospitals was held at Gallipolis April 6 and 7. Dr. William H. Pritchard, Gallipolis, was elected president, Dr. Paul W. Tappan, Dayton, vice-president; Dr. Walter H. Buhlig, Gallipolis, secretary, and Dr. F. Day Ferneau, Toledo, treasurer.

Exclusion of Eddyites Held Unconstitutional.—In the Common Pleas Court, Sandusky, April 18, this afternoon, Judge Reed ruled that the state medical law is unconstitutional because it limits the right to practice without the use of drugs or medicines to osteopaths, and by the rule of exclusion Eddyites are prohibited. He said it should be amended to allow for a reasonable examination of Chrisitian Scientists and for their registration.

PENNSYLVANIA.

Paralyzed.—Dr. Julius A. Stricker, Portage, was stricken with paralysis, April 17, and is still seriously ill.

Bequest.—By the will of Dr. Cyrus R. Stuckslager, McKeesport, $5,000 is bequeathed to the McKeesport Hospital.

Health Board Appointments.—Dr. Louis P. McCormick, president, Connellsville; Dr. Calvin F. McDowell, city phyiscian, Newcastle; Dr. W. Knowles Evans, vice-president, and Dr. Franklin J. Evans, city physician, Chester.

Go to Another Hospital.—Drs. J. Purd Kerr, of the gynecological and surgical staff, and Charles H. Hertzog, of the surgical staff of the South Side Hospital, Pittsburg, have resigned to become members of the staff of St. Joseph's Hospital, which is to open May 1.

Graduate Nurses to Fight Impostors.—The Graduate Nurses' Association met in session in Wilkesbarre, April 20, to frame legislation compelling the registration of all graduate nurses in order to protect the public against impostors. An effort will be made to have the necessary legislation passed at the next meeting of the legislature; committees were appointed for that purpose.

Philadelphia.

Bequests.—By the will of the late George Huster the following institutions have been benefited: St. Mary's Hospital, St Joseph's Hospital, and St. Vincent's Home and Maternity Hospital, $1,000 each.

Cancer Annex Fund.—The managers of the Philadelphia Home for Incurables have not appealed in vain for funds to erect a new cancer annex. Within two months they have received donations amounting to $22,000, varying in amount from $1 to $10,000.

Inspection of Abattoirs.—At the last executive session of the health board, rules and regulations were drafted for a thorough sanitary inspection of slaughter houses, abattoirs and butcher shops. This step was taken as a result of the recent work of the medical inspectors, who reported many of these places in a very unsanitary and filthy condition.

Exposure of Baby Farms.—The *Philadelphia Press* has been devoting special attention to the exposure of existing abuses due to lax legislation with reference to midwives, the registration of births, lying-in hospitals and baby farms. Much public sentiment has been aroused, and it is proposed that at the next meeting of the legislature a bill shall be presented adequately and fully to meet the needs of the city. Every effort will be made to secure the passage of the bill. For this purpose the *Press* has appointed a commission to draw up a statute covering these subjects. The commission is composed as follows: Drs. John G. Clark, Charles E. Cadwalader and Edward E. Montgomery; Mr. George Wharton Pepper, representing law, and Mary E. Richmond, secretary of the organization of charities.

Typhoid Unabated, Increase in Smallpox.—The epidemic of typhoid fever remains unabated, the total cases reported during the week being 352. This is seven less than last week. There were 14 deaths from the disease during the week, a decrease of 15 over the preceding week. That portion of the city supplied with filtered water remains particularly free from the malady. ——*A fresh outbreak of smallpox* has occurred. The new cases reported during the week numbered 32. This is an increase of 7 over last week's report. Nine deaths resulted from the disease, as compared with 5 reported for the preceding seven days. The cases reported are not confined to any particular section, but are scattered throughout the city. The general death rate still continues high, 594 deaths being reported. This is an increase of 24 over those of last week, and an increase of 74 over the corresponding period of last year. Two deaths were due to hydrophobia.

WISCONSIN.

Accident.—Dr. Helen A. Harbert, Kenosha, recently sustained severe internal injuries. An automobile collided with her buggy and she was thrown out.

Want Unisolated Isolation.—The Milwaukee Medical Society has adopted resolutions opposing the plan to remove the isolation hospital outside of the city limits.

Pneumonia.—During March, 74 of the 439 deaths in Milwaukee, or nearly 17 per cent. were due to pneumonia, a larger number and percentage than have ever before been recorded in the city.

Impugns State Board's Motives.—In a petition for a peremptory writ of mandamus filed April 16, the State Board of Medical Examiners is charged with conspiracy and with entering into an illegal and malicious agreement to refuse to recognize the Harvey Medical College of Chicago.

GENERAL.

Another Medical Daily Gives Up.—The *Daily Medical*, which was to revolutionize medical journalism in this country, has ceased to exist. This was the third medical daily to start, and to die, in the United States; evidently there is no great demand for such a publication.

FOREIGN.

Dental Hospital for School Children.—Strasburg has appropriated $80,000 to build a dental hospital for its school children.

Institute for Treating Hernia.—A "Bassini Institute" is planned at Milan to supply operative treatment of hernia to the poor. The subscriptions have now reached nearly $3,000.

Sale of Opium at Smyrna.—The *Riforma Medica* states that 520,000 kilograms of opium, more than a million pounds, are sold at Smyrna each year. A fourth of the entire amount is purchased for the European markets.

Unprecedented Meeting of the Paris Academy of Medicine.—After the official opening of the regular meeting of the Académie on April 12, it was found that there was absolutely nothing on the order of the day, and the solemn conclave adjourned.

Russian Physicians at the Seat of War.—Among those who have left for the far east we note the well-known names of Professors E. Masing jun. and Zoege von Manteuffel of Dorpat. An interesting series of letters from the former is being published in the *St. Petersburger med. Woch.*, written in German.

Shall a Physician Refer His Patients to Certain Pharmacists?—A medical society in Paris has recently been discussing this question, and concluded in favor of the view that it is the physician's right and even duty—under existing conditions—to tell his patients to have his prescriptions made up at certain pharmacies in preference to others.

Anniversaries Among Our German Confreres.—The fiftieth anniversary of the entrance on their professional career has recently been celebrated by Drs. H. A. Müller of Hamburg, A. Bode of Cassel and Salzer of Worms. We also note that the friends of Prof. W. Hittorf, the physicist who discovered the cathode rays, celebrated his eightieth birthday March 27.

Cooking for the Sick.—Vienna has opened a restaurant modeled on the successful ones in Germany, which are exclusively devoted to the task of supplying food to sick persons. They are semi-charitable undertakings and the physicians are finding them a great aid in the treatment of patients in poor or moderate circumstances. The meals are delivered at the homes, kept warm in thermophore dishes.

Professor Pozzi Coming to America.—The *Revue Médicale du Canada* states that it has learned that the University of Paris has appointed Professor Pozzi as its representative to the Congress of French-speaking Physicians, to be held at Montreal, June 28. Prof. S. J. Pozzi is the famous gynecologist, editor of the *Revue de Gynécologie.* He is now in his fifty-ninth year, and will receive a warm welcome from the profession in America.

Vaccination of the Kaiser's Children.—The report has been current in Germany that the children of the imperial family had never been submitted to vaccination. The official organ of the post-graduate courses asked permission to publish a statement from the Kaiser's physician, Dr. von Leuthold, in regard to the facts. The statement was officially made that the children had all been vaccinated strictly in accordance with the ordinances and revaccinated at the proper age.

Preservation of the Old Medical School in Paris as a Historical Relic.—The city council of Paris has yielded to the pressure brought to bear by the medical profession and has decreed that the most ancient part of the old faculté de médecine in the rue de la Bucherie shall be set apart as a historical monument. The property was bought by the city eight years ago for $60,000, but nothing has been done further to date. The building will need considerable restoration before it can be utilized as a museum and library, which is the present plan. Part of some of the buildings dates from 1369, and other parts from 1499.

Syphilization of Apes on Their Native Soil.—As the anthropoid apes almost inevitably succumb rapidly to tuberculosis when imported into Europe, a project has been formed to seek them in their native haunts to carry on the research in regard to their inoculation with syphilis. An expert bacteriologist will be sent to Borneo or Sumatra with facilities for the search for an efficient antitoxin serum against syphilis, utilizing these apes for the subjects if sufficient funds can be raised for the purpose. Metchnikoff of Paris and Lassar of Berlin are the moving spirits in the project. Each of them has had remarkable success, they think, in their inoculations of chimpanzees, as duly chronicled in these columns in the last few months.

The Japanese Hospital Ships.—Japan ordered as long ago as the middle of the nineties two hospital ships to be built in England, and they have since been in readiness for a war. During peace times they are leased to a passenger and freight line, but were used for their special purposes during the campaign of 1900. They made then about fifteen trips from China to Japan, conveying nearly 3,000 wounded to the hospitals in Japan, including a number of men belonging to the European armies of occupation. Each vessel is about 300 feet long, we are informed, 40 feet wide, of 2,700 tonnage, and they are constructed so that they can be used in waters not exceeding 20 feet in depth. The upper deck is for the officers of the Red Cross Society, with saloons, bath rooms, etc. The middle deck is the hospital proper, and the lower deck for the male nurses, the store rooms, etc. Each ship has accommodations for 200 patients. Further details are given in the *British Medical Journal* for April 16, and in the *Caducée,* a French medical magazine.

The Russian Wounded.—The Russian Red Cross Society has provided supplies for 5,710 beds, in addition to the flying squadrons, the total being now 6,435. A fleet of boats is being prepared to serve as floating hospitals on the Amur and Ussuri rivers. Disinfecting battalions have also been organized. During the last war in the Far East the society spent over eight million dollars, but now has scarcely more than a third of this sum at its disposal. The nobility of twenty-five different "governments" has raised a fund of more than half a million dollars, and is applying it to the aid of the sick and wounded. The Moscow clinics have appropriated a hundred beds for the wounded returning from the war, the professors volunteering to personally defray the expense. The clinics and university of Tomsk, by imperial orders, are also being put in readiness for the reception of wounded. By the last week in March the Red Cross had despatched to the seat of war 744 persons—physicians, students, nurses and attendants, and 445 more are on the point of leaving or have gone since.

Correspondence.

The Composition of Some So-called Synthetics and "Ethical" Nostrums.

PHILADELPHIA, April 20, 1904.

To the Editor:—One of the noblest attributes of the character of an American is his desire for fair play; and one of the fundamental principles of American justice is that the accused party is considered innocent until proved guilty.

The comments published in the issue of April 16, 1904, under the above heading, insomuch as they refer to products of our manufacture, are not in accordance with the facts.

First, as to thermol, concerning which it is stated that this "wonderful new discovery is nothing but impure phenacetin." Would it not be more to the point to definitely state what that impurity is? and in what quantity? As to the explanation that "possibly traces of salicylic acid have been added to the product from time to time," that would lead one to think that salicylic acid had been added in a mechanical way merely for effect. We will state that perhaps some traces of salicylic acid may be detected from time to time, because in the process of crystallization some of the same may be split off from the original chemical compound, which is not unusual in any chemical of the kind. This same fact happened to Kraut when he crystallized his acetyl salicylic acid and led him astray on his melting point.

The chemist ascertains the composition of molecules by two methods: First, by analysis, which consists in separating the molecule into its constituent atoms. Second, by synthesis, which consists in putting together the constituent atoms to form the molecule.

Unfortunately, the chemist never lived who could make an analysis—a resolution of the whole into its first elements—of an aromatic compound of this class. Therefore, the only manner of truthfully ascertaining the composition of molecules of an aromatic compound of this character is by synthesis.

In making acetyl-salicyl-phenetidin we put the proper molecular proportions of acetic and salicylic acids into the autoclave with the phenetidin (60 pounds of salicylic acid to 59 of phenetidin) and when the chemical reaction is over we remove the newly formed chemical compound and proceed to purify the same. We first wash it with a thin soda solution to remove any uncombined acid, then we wash it with a solution of muriatic acid to remove any uncombined phenetidin. The first washing is afterward made acid with muriatic acid to recover what there is of any uncombined salicylic acid. The proportion that is recovered is but a mere trace of the total amount used, and this fact is proof positive that the salicylic acid has become part of that chemical compound. These facts we can most readily prove by the voluntary oaths of our workmen, and we can also show the signature of the most able chemist, Sadtler, to further substantiate them.

Why not let the owners of the phenacetin patent settle this matter for themselves in the United States Court?

Next, as to bismuth oxyiodid methylene digallate (named by us iodomuth), of which the article says, "according to analysis is merely bismuth gallate with a small quantity of free gallic acid; no iodin could be traced in the examined specimen." What methods were used to detect the iodin? What became of the formaldehyd that had been so firmly united to the gallic acid? Professor Sadtler demonstrated at the time when application was made for U. S. letters patent that it contained over 24 per cent. of iodin, and we can readily prove that we have never made a grain of this chemical since that demonstration except in exact accordance with the process there set forth.

Now, as to urasol, which is referred to as the "greatly boosted wonderful remedy"—acetyl-methylene-disalicylic acid —which this article says is an "impure methylene salicylic acid," that can be readily produced.

We do not deny that methylene *di*salicylic acid can be readily produced, after the idea has been created, but we do deny the ability of the critic to produce "methylene salicylic acid."

Again, as to impurity. What is this impurity? We make and sell both the methylene disalicylic acid and the acetyl methylene disalicylic acid. Which of the two was tested? There is a vast difference between them. Here, again, Professor Sadtler verified the correctness of our chemical by testing at the time of applying for patents.

Should the Heyburn Pure Food Bill become a law, it will not interfere in the least with the sale of our products in any state of our union.

Let us state in closing that this most evident partisanship is unfair. Why is not the purity of the products of our foreign competitors questioned? Perhaps they fear that the brains which produced the ideas that are responsible for these new chemicals, which have been abundantly confirmed by the United States Patent Office, might take away from them some of the profits that they have been reaping in the American market.

The able clinician's who study the physiologic actions of their remedies are able to learn the therapeutic efficiency of the same. Yours very respectfully,

S. Lewis Summers,
Organic Chemical Manufacturing Company.

Death and Blindness from Wood Alcohol.

Chicago, April 23, 1904.

To the Editor:—The following circular letter has been sent to members of the Section on Ophthalmology of the American Medical Association and to some other physicians who would be most likely to furnish the desired information. If any of your readers, who have not received the circular, will assist in the investigation, by sending a report of unpublished cases, it will be gratefully received and acknowledged:

> In my judgment the time has arrived for placing preparations containing wood alcohol on the list of poisons. It would also, in my opinion, be appropriate if the initial steps were to proceed from the Section on Ophthalmology of the American Medical Association. As representative of that body in the House of Delegates I am gathering evidence to prove the toxicity of methylated preparations, a short account of which I propose to lay, first of all, before the Section, and then, by resolution, before the House itself. In that way pressure can be exerted on the various states in the hope of inducing appropriate legislative action.
>
> Will you kindly assist in this work by sending me a short account of any unpublished case of death or blindness, *personally* known to you, that has followed the ingestion of wood alcohol? I especially desire particulars as to the form of the poison—whether taken as Columbian spirits, Jamaica ginger, essence of lemon or peppermint, cologne spirit, etc., or as ordinary beverages adulterated with methyl alcohol. The results of analyses of these preparations will be of especial value in this investigation.
>
> Occasional descriptions of methyl-alcohol intoxication are published in the smaller general medical journals or mentioned only in the local press Clippings from these sources would also be welcome.

103 Adams Street. Casey A. Wood.

Use of Ether at Battle of Wilderness.

Boston, April 23, 1904

To the Editor:—I am sorry to see in The Journal of this date a "magazine written" article, mainly for the purpose of repeating the old falsity that W. T. G. Morton discovered and introduced ether anesthesia, when he himself at first acknowledged that Dr. C. T. Jackson gave him the prescription with directions, later given to Massachusetts General Hospital and by it given to the world. Jacob L. Williams, M.D.

Marshall, Tex., April 25, 1904.

To the Editor:—It would appear to one of your southern subscribers and a son of one of those "rebels" "who did not generally fire on those wearing the ambulance badges," that the article in The Journal, April 23, entitled "The First Use of Ether as an Anesthetic at the Battle of the Wilderness in the Civil War" is more of a laudatory article on the exceptional valor of the pension drawers than one of interest to medical men. What is said of ether would not occupy ten lines in the article, which is made up of heroic federal and vanquished rebel.

Believing The Journal to be non-partisan as much for the conquered rebel as for the victorious federal, I was surprised and grieved to find any such article in its pages.

Charles E. Heartsill, M.D.,

Queries and Minor Notes.

THE SO CALLED ABSORPTION TREATMENT OF CATARACT.

Converse, Ind., April 13, 1904.

To the Editor:—Is there any remedy that will remove the opacity of the lens in the condition commonly termed cataract? Is there anything in the so-called absorption or disintegration cure? There are thousands who fall into the hands of the so-called curist. Are any cures wrought from this manner of treatment, and if so, what is it? Some have come under my observation who have apparently been benefited, but would they not have been better without any medications? M. Caton Kimball.

Answer.—The ordinary forms of cataract are due to structural changes in the lens, whose fibers, previously as transparent as clear glass, are converted into an opaque substance comparable to ground glass. In rare instances, such as in the early stages of cataract from diabetes, the opacity in the lens may be due to exudates thrown out between the fibers, and not to actual destruction of the lenticular tissues. This form of cataract is a rare exception to the rule, and if the disease that gives rise to it progresses (as it commonly does) the crystalline fibers themselves are eventually destroyed and their place taken by opaque material, as in the senile or other common forms of cataract. Bearing in mind these facts one can readily understand how absurd is the "absorption" or any other "cure" of genuine cataract. Neither manipulation of the eyeball nor local applications, however mild or severe, will avail to restore the destroyed lens fibers. One might as well expect to "absorb" an organic lesion of the cardiac valves by rubbing liniment over the left breast. Apparent improvement or cure of cataract by these methods are mostly due (1) to the imagination of the patient, (2) to the fact that the dulled vision arose partly or altogether from a curable eye disease not situated in the lens (*some corneal affection, for example*), or (3) to the absorption of a diabetic deposit in the lens substance which underwent a partial or total absorption coincident with improvement in the systemic condition. In all these cases the improvement might occur with or without treatment. It must be remembered, also, that improvement in the vision of cataractous eyes sometimes takes place for a time if the local health of the ocular apparatus is improved by rest and soothing applications, or if the pupil be kept dilated by *atropia* or other mydriatics. Finally, there are such lenticular opacities as "stationary" cataracts; the disease progresses to a *certain* extent and then, without any particular reason, remains in *statu quo* for many years. Doubtless the "absorption cure" has often received credit for this form of "improvement."

COMMISSIONS.

Richmond, Va., April 21, 1904.

To the Editor:—A and B are members of one school and C is a member of another school, A and C being surgeons, while B is a general practitioner. Because A will not divide fees with B, the latter throws his surgical cases into the hands of C, who will divide. How about the ethics involved, and would the membership of B or C in the A. M. A. be affected under the circumstances?

Query.

Answer.—Membership in the American Medical Association depends on membership in the county society, consequently the question with which our correspondent concludes is one that belongs to the county society. The Principles of Medical Ethics of the A. M. A. says: "It is derogatory to professional character for physicians to pay or offer to pay commissions to any person whatsoever who may recommend to them patients requiring general or special treatment or surgical operations. It is equally derogatory to professional character for physicians to solicit or to receive such commissions." (Sec. 4, Article 6, Chapter 2.) We answer with entire disregard of our correspondent's statement concerning "one school" and "another school."

ATAVISM IN THE NEGRO.

Salem, Mass., April 24, 1904.

To the Editor:—I have been interested in the following discussion: Can an octoroon woman married to a pure white man give birth to a pure negro child, or one of darker skin than herself? May she give birth to a white child with all the facial characteristics of the negro? Is there such a thing as a prevert in a case of this character? Authorities seem to disagree and I was informed you might give me some information. H. A. C.

Answer.—Such reversions, we believe, are not only possible but probable as occasional occurrences. These reversions are likely not to be complete, but we could not say that such would be impossible. We are under the impression—this also without support of statistics—that they are more common with the white mother and hybrid father than when the reverse is the case.

PATIENT IS FREE TO CHOOSE PHYSICIAN—CONDUCT OF LOCUM TENENS.

T. O. sends these two queries: 1. A calls B in consultation or to give anesthetic. The family are favorably impressed by B. and when next they need a physician call in B. B takes the case. Is this taking the case unfairly? If not, should B give any explanation of his conduct to A. 2. A leaves the city for a few weeks. He leaves word with certain patients that if they are ill in his absence to call in B. The patients are ill during A's absence and B is called in. On the return of A is B under any obligation to send the patients to A?

Answer.—1. B can not restrict the liberty of the patient to choose his physician and is not technically unethical in taking the case. He should not be active in the change and might well explain this to A. 2. B is practically a locum tenens for A and acts accordingly, turning over the case to A on his return. In each instance the application of the golden rule will solve the problem.

FORMULA FOR CANCER PASTE.

Granville, Fla., April 16, 1904.

To the Editor:—Kindly give me through The Journal the formula for Bougard's paste for epithelioma. A. E. Canter.

Answer.—

℞. Wheat flour and starch, of each	60 parts.
Arsenic	1 part.
Cinnabar and salammoniac, of each	5 parts.
Corrosive sublimate	½ part.
Col chlorid of zinc. at 52°	245 parts.

M. Grind the first six ingredients to a fine powder, then mix them in a mortar. Add the solution of zinc chlorid, stirring slowly. Keep in an earthen jar. Cocain may be added up to 20 per cent. to allay pain. Sig.: Apply accurately to the part; keep on for thirty hours; follow with a poultice.

SPECIALIST ON EVERYTHING—ANOTHER LETTER HEAD.

Our comment on a letter head last week has brought out another that is worthy of note. On it appears an illustration (3 by 4 inches) of a nebulizer. The wording is as follows:

OFFICE OF DR. —. —. ———.
PHYSICIAN and SURGEON.
Tel. ——-—. ——— —. ——— St.
Specialist on Obstetrics, Diseases of Women, Diseases of
Chest, Throat and Nose, Diseases of Stomach, Genito,
Urinary and Intestinal Tract, Nervous, Surg-
ical Diseases, Etc.

TURTLE SERUM.

A subscriber of St. Louis writes very indignantly regarding the letter on the above subject by Dr. Howle, of Charleston, Mo., published in this department two weeks ago. Our St. Louis correspondent thinks the letter an insult to our foreign scientific men and periodicals. He thinks that it was a sneer at rivals because they are of another nationality. We are very much afraid that hereafter we shall have to label the jokes that are allowed to appear, even though they are published for a good purpose.

NO RECIPROCITY BETWEEN ILLINOIS AND WASHINGTON.

Davenport, Iowa, April 10, 1904.

To the Editor:—Please tell me through The Journal whether the state of Washington reciprocates with Illinois, and whether my certificate of the Illinois State Board of Health will permit me to practice in Washington without further examination by that board.

J. D. Crawford.

Answer.—No.

A WORK ON CLIMATOLOGY.

Dr. A. B. Stewart, Owatonna, Minn., answering a query in The Journal, March 19, 1904, recommends as a work on climatology the one by Dr. S. Edwin Solly, Denver, published by Lea Brothers & Co., Philadelphia and New York.

Deaths.

Israel Thorndike Dana, M.D. Harvard University Medical School, Boston, 1850, one of the founders of the Portland School for Medical Instruction; for a number of years professor of materia medica and theory and practice of medicine in the Medical School of Maine; one of the founders and sometime president of the Maine Medical Association, and of the Cumberland County Medical Society; and one of the founders of the Maine General Hospital, died at his home in Portland, April 13, after a long period of enfeeblement, aged 76.

Edward J. McGorrisk, M.D. Medical Department of St. Louis University, 1855, successively surgeon of the Seventeenth Iowa Volunteer Infantry brigade and division surgeon and medical director of the Fifteenth Army Corps in the Civil War, a pioneer practitioner of Des Moines, Iowa, sometime surgeon general of Iowa, died at his home in Des Moines, April 16, after a lingering illness, aged 69.

Charles Kerr, M.D. Rush Medical College, Chicago, 1865, during the Civil War assistant surgeon of the Fifty-ninth Illinois Volunteer Infantry; a member of the American Medical Association, representative in the state legislature in 1884, a resident of Springfield, Ill., since 1885, died at St. John's Hospital in that city, April 13, from cardiac asthma, after a long illness, aged 66.

Edward H. Lee, M.D. Royal College, Würzburg, Germany, 1892, staff surgeon at Cook County, Alexian Brothers and West Side hospitals, Chicago, was almost instantly killed by falling over the railing of a staircase at the Chicago Athletic Club, from the ninth floor to the rotunda, a distance of 125 feet, early on the morning of April 24, aged 36.

David L. Bailey, M.D. New York University, 1875, first president of the Carbondale (Pa.) Board of Health, and of the Emergency Hospital; a member of the Carbondale and Lackawanna County medical societies, died at his home in Carbondale, April 13, from septicemia due to an operation wound, after an illness of one week, aged 53.

Wilbur F. Nutten, M.D. College of Physicians and Surgeons, New York, 1863, member of the American Medical Association, New York State Medical Association and Wayne County Medical Society, one of the best-known practitioners of western New York, died suddenly from heart disease at his home in Newark, N. Y., April 19, aged 64.

Edwin L. Randall, M.D. Missouri Medical College, St. Louis, 1869, dean and professor of theory and practice of medicine in Knoxville Medical College; a member of the East Tennessee and Knox County medical societies, died from pneumonia at his home near Knoxville, Tenn., April 18, after an illness of two days, aged 50.

Oscar H. Huntley, M.D. Jefferson Medical College, Philadelphia, 1856, surgeon in the First Illinois Volunteer Cavalry in the Civil War, a member of the Bureau County Medical Society and the oldest practitioner in the county, died at his home in Buda, Ill., from pneumonia, April 18.

Josiah D. McVay, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1873, member of the Iowa House of Representatives in 1883, and state senator from 1887 to 1891, died suddenly from heart disease at his home in Lake City, Iowa, April 10.

John W. Adams, M.D. Beaumont Hospital Medical College, St. Louis, 1887, professor of physical diagnosis in the St. Louis College of Physicians and Surgeons, died from heart disease at his home in St. Louis, April 9, aged 39.

Ignatz Friedmann, M.D. University of Budapest, Austria, 1866, of Cleveland, a member of the American Medical Association, was killed in that city, April 21, as the result of a collision between his carriage and a street car.

Abner Alexander, M.D. Baltimore Medical College, 1877, of Columbia, N. C., repeatedly representative from Tyrrell County in the General Assembly, died in Johns Hopkins Hospital, Baltimore, April 9, aged 65.

William T. Beach, M.D. Jefferson Medical College, Philadelphia, 1863, for many years secretary of the Schuylkill County Medical Society, died at his home in Minersville, Pa., April 8, after a long illness, aged 64.

Benson Knox, M.D. Arkansas University, Little Rock, 1886, several times president of the Hill County (Texas) Medical and Surgical Association, died at his home near Woodbury, April 15, aged 65.

C. Norton Mourning, M.D. Hospital College of Medicine, Louisville, 1900, assistant to the chair of abdominal surgery in that institution, was found dead at his home in Louisville, April 16.

Henry Polk Robson, M.D. Birmingham (Ala.) Medical College, 1902, of Snow Hill, Ala., was run over and killed while attempting to board a freight train at Wallace, Ala., April 13.

Lorenzo J. Kohnstamm, M.D. New York University, 1889, died from general paresis at the Manhattan State Hospital for the Insane, April 18, after an illness of four years, aged 42.

Charles M. Nodler, M.D. Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1902, died at his home in Denver from tuberculosis, after a long illness, aged 44.

Deaths Abroad.

Sir Henry Thompson, Bart., F.R C.S. England, 1853; M.B. London, 1851, the eminent surgeon, teacher and writer, died at his home in London, April 18, aged 83. He was a fellow of the Royal Medico-Chirurgical Society and Royal Medical Society of London; a member of the Pathological and Harveian societies.

and an honorary member of many foreign societies. He was made professor of pathology and surgery in the Royal College of Surgeons in 1884, and was president of the Cremation Society since its organization in 1874. His most famous work was in the pathology and surgery of the prostate, bladder and urinary passages.

Samuel Smiles, M.D., Edinburgh, LL.D., made famous by his series of perseverance works, "Self-Help," "Thrift," "Character," "Duty," "Invention and Industry," and "Conduct," also a journalist and secretary of the Leeds and Thirsk and afterwards of the Southeastern Railway Company, died April 16 at his house in Kensington, London, after a long illness, aged 91. He was known as the apostle of perseverance, for perhaps no book of modern times has taught so admirably what may be accomplished by continued effort as has his volume "Self-Help."

I. Rosenthal, M.D., professor of physiology at Erlangen, and author of many papers on animal heat, calorimetry, electrophysiology, etc., died recently. His last work was a book on "Instruction in Physiology," dealing especially with its importance in the education of medical students. He advocated the use of physiology as a discipline to educate the logical powers of the student.

A. de-Martino, M.D., a prominent figure in Italian medical and political life, long professor of obstetrics at Naples and family physician to the reigning family, died at Naples, February 29, aged 84.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S Army, week ending April 23, 1904:

Pipes, Henry F., and Bingham, E. G., asst.-surgeons, on arrival at San Francisco, en route to Manila, P. I., commanding general, Department of California, authorized to assign them to duty with troops going from Presidio of San Francisco to Yosemite and Sequoia National Park, Cal, for duty during season of 1904, then to proceed to Manila, P. I.

Rutherford, Henry H, asst. surgeon, granted thirty days' sick leave of absence

McAndrew, P. H, asst.-surgeon, leave of absence extended fifteen days.

Waterhouse, Sam'l M, and Edger, Benj F., Jr., asst surgeons, ordered to report in person to Lieut Col. Geo. H. Torney, deputy surgeon general, president examining board, Presidio of San Francisco, for examination for promotion.

De Witt, Wallace, asst-surgeon, granted seven days' leave of absence.

Banta, Wm P, asst. surgeon, on relief from duty at target range, Leon Springs, Texas, to proceed to Kerrville, Texas, for duty at the artillery camp at that place

Wells, Francis M, contract surgeon, has received an extension of two months to his leave of absence from the Division of the Philippines

Tignor, Edwin P, contract dental surgeon, left Fort Mackenzie, Wyo, April 15, for Fort Riley, Kan, his proper station, arriving on the 17th.

Reddy, Joseph, contract surgeon, granted two months' leave of absence from the Philippines Division,

Shellenberger, James E, contract surgeon, left Fort Ringgold, Texas, April 17, for his new station, Fort Sam Houston, Texas, and has been ordered thence to duty at the target range, Leon Springs, Texas

Navy Changes.

Changes in the medical corps, U S Navy, for the week ending April 23, 1904:

Stone, E P, surgeon, detached from the *Mayflower* and ordered to the Naval Academy.

Pryor, J. C, P. A surgeon, ordered to the Naval Hospital, Newport, R. I.

Holcomb, R. C, P. A surgeon, detached from the Naval Hospital, Newport, R I, and ordered to the *Mayflower*

Strite, C E, A A surgeon, appointed A. A surgeon from April 13, 1904

Lowndes, C H T, surgeon detached from the Naval Academy and ordered to the *Chesapeake*

De Valin, C M, P A surgeon, detached from the *Rainbow* and ordered to the *Albany*

Traynor, J P, asst surgeon, detached from the *Albany* and ordered to the *Rainbow*

Arnold, W. W, surgeon, retired from active service April 19 1904

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service, for the seven days ended April 21, 1904:

Brown, B W, P. A surgeon, granted leave of absence for two days from April 25

Blue, Rupert, P A. surgeon, granted leave of absence for three days from April 19

Greene, J B, P. A surgeon relieved from duty at Havana, Cuba, and directed to report to the medical officer in command at New York (Stapleton) for duty and assignment to quarters

Holt, J M, asst surgeon, to report to medical officer in command at San Francisco for duty and assignment to quarters

McLaughlin, A. J, asst surgeon, granted leave of absence for four days from April 20

Warren, B. S., asst. surgeon, granted extension of leave of absence for one day from April 17.

Ashford, F. A., asst surgeon, leave of absence for ten days from March 28, 1904, amended so that said leave shall be for eleven days.

Altree, G. H, A. A. surgeon, granted leave of absence for five days from April 19.

Bailey, C. W., A. A. surgeon, granted leave of absence for eleven days from April 22.

Duke, B. F, A. A. surgeon, granted leave of absence for eight days from April 18.

Marsh, W. H., A. A. surgeon, granted leave of absence for five days from April 26.

Moncure, J. A., A. A. surgeon, Department letter of March 31, 1904, granting leave of absence for thirty days from April 10, 1904, amended so as to read thirty days from April 12.

Iltis, G. W., pharmacist, granted leave of absence for twenty-five days from May 5.

Medical Organization.

Illinois.

Knox County Medical Society.—At the fifth semi-annual meeting, held at Galesburg, April 19, the society adopted the standard constitution and by-laws, reorganized, and elected the following officers: President, Dr. Alexander F. Stewart, Oneida; vice-president, Dr. Lawrence R. Ryan, Galesburg; secretary-treasurer, Dr. George S. Bower, Galesburg; censors, Drs. Louis Becker, Knoxville; William O'R. Bradley, Galesburg, and Charles F. Bradway, Abingdon, and Dr. Lawrence R. Ryan, Galesburg, delegate to the state society.

Iowa.

Medical Association of Clinton County.—This association was organized at Clinton, April 13. A temporary organization was first effected, with Dr. Joseph C. Langan, chairman, and Dr. Harry R. Reynolds, secretary. The standard constitution and by-laws was adopted, after which permanent officers were elected as follows: Dr. George A. Smith, president; Dr. Herbert R Sugg, vice-president; Dr. E. L. Martindale, secretary and treasurer; Dr. John H. F. Sugg, delegate to Iowa State Medical Society; Dr. Christian Jonsson, alternate, and Drs. George Hofstetter, Joseph K. Milbourne and Robert E. Everhart, censors, all of Clinton.

Kansas.

Allen County Medical Society.—The physicians of the county met in Iola, April 13, and organized a medical society on the standard plan with 17 members and the following officers: President, Dr. Paul S. Mitchell, Iola; vice-presidents, Drs. James E. Jewell, Moran, and Joseph H. Hindman, Humboldt; secretary and treasurer, Dr. John W. Bolton, Iola, and censors, Drs. William R. Heylman, Iola, Charles W. Rennick, Gas, and Harry V. Dresbach, Iola.

Maryland.

Baltimore City Medical Society.—The Baltimore Branch of the Medical and Chirurgical Faculty of Maryland, under the new organization, met, April 15, and organized on the standard plan with the following officers: President, Dr. Harry Friedenwald; vice-president, Dr. Isaac E. Atkinson; secretary, Dr. John Ruhrah; treasurer, Dr. Thomas A. Ashby; censors, Drs. John I. Pennington, Henry B. Thomas and James M. H. Rowland; delegates to medical and chirurgical faculty, Drs. William S Thayer, Samuel T. Earle, John S. Fulton, Robert S. Reik, John D. Blake, Charles O'Donovan, Herbert Harlan, William S. Gardner, and C. Urban Smith.

Mississippi.

Hinds County Medical Society.—The physicians of the county met at Jackson, April 15, and organized a county medical society with the following officers: Dr. Thomas M. Price, Raymond, president; Dr. Archibald McCallum, Edwards, vice-president, and Dr. Osborn M. Turner, Jackson, secretary-treasurer

West Virginia.

Barbour, Tucker and Randolph County Medical Society.—The medical society of Barbour, Tucker, and Randolph counties was organized recently at Elkins, with 30 members and the following officers: President, Dr. J. Calvin Irons, Elkins; vice-presidents, Drs. S. D. Few, Parsons, and D. W. Brown, Bellington; secretary, Dr. Frank B. Murphy, Philippi; treasurer, Dr. E. H. Stump, Philippi, censors, Drs. Irwin Hardy, Davis, O. L. Perry, Junior, and Humboldt Yokum, Beverly.

Wisconsin.

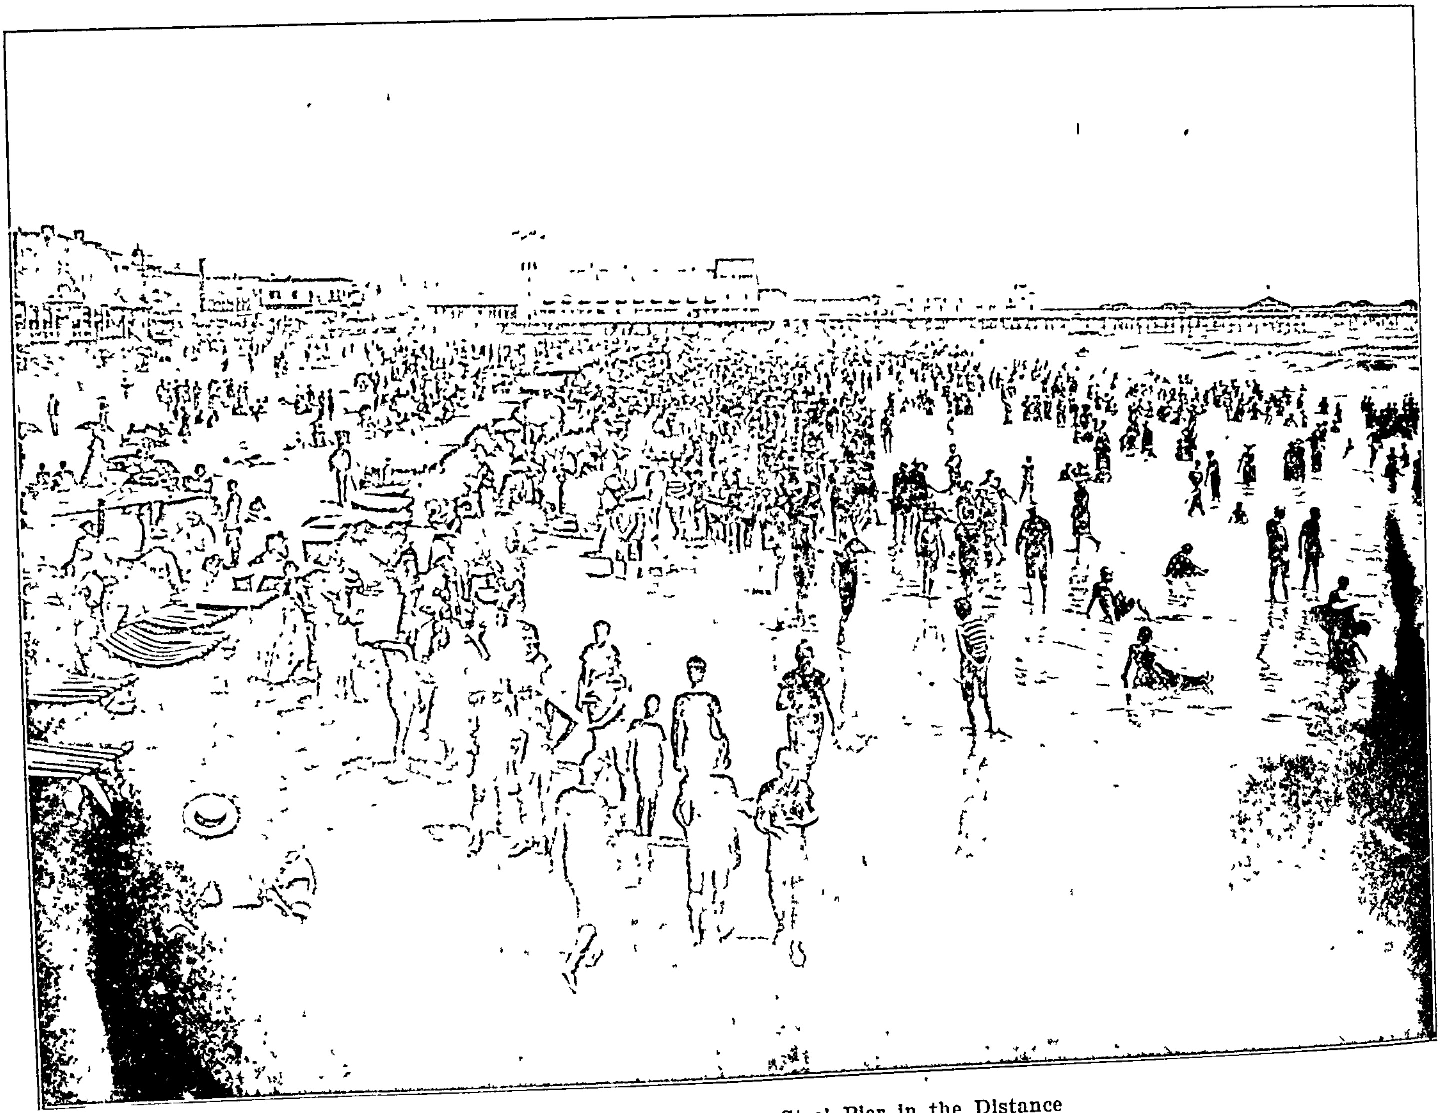
Tenth District Medical Society.—The physicians of the tenth congressional district recently met at Rhinelander and organized a district medical society, of which Dr. Ignatius D. Steffen, Antigo, was elected president, and Dr. Thomas J. Hembley, Hurley, secretary and treasurer.

THE ATLANTIC CITY SESSION

American Medical Association, Fifty-Fifth Annual Session, Atlantic City, New Jersey, June 7 to 10, 1904

THE GREATEST RESORT IN AMERICA—THE SCENE OF THE 1904 SESSION.

A few years ago an eminent physician, after spending four years in traveling through all parts of the United States, and in visiting numerous resorts for health, publicly expressed the opinion that Atlantic City was destined to become "the greatest, most popular and most widely known resort on the American Continent—perhaps in the world." That prophecy to-day is fulfilled. With a permanent population of 35,000, it stands apart, in a class of its own, distinct from the ordinary summer settlement. With a midsummer population verging on 250,000, it boasts itself to be the largest city on the Atlantic coast south of New York. With its present rate of growth and popularity as a resort for health and pleasure in every month of the year, it will in the near future attain such proportions as now it might seem extravagant to predict. And perhaps the most confidence-inspiring feature of the whole case is that all this vast development is on the sure and certain basis of actual and demonstrated worth. Atlantic City deserves to be the great resort it is and the greater resort it will be. That is the fact on which its hope is based, and of the soundness of which every appreciative visitor is speedily convinced.



Midsummer Bathing Scene; Steel Pier in the Distance

THE LENTEN SEASON.

After all that can be said of Atlantic City as a summer resort, its most charming social feature is during Lent. It is then that the fashionable hotels and boarding houses are thronged with the wealthy people, who seek seclusion and rest during the penitential season. The fashionable come from their giddy round of social pleasures, the professional men and women from their studies, the merchant from his perplexing ledger, the politician from his nagging constituents, and youth and beauty to see and be seen of each other. It is the season of quiet, but is not devoid of pleasure. There are dainty musicales, readings and recitals almost nightly in the hotels. The great cosmopolitan throngs have not yet invaded the hotels, quiet dignity prevails and the hotel colony takes on much of the appearance of a family reunion. It is a season when lasting friendships, not petty flirtations, obtain; when the effervescence is missing, and the solid, tangible side of life is in evidence.

A YEAR-ROUND HEALTH RESORT.

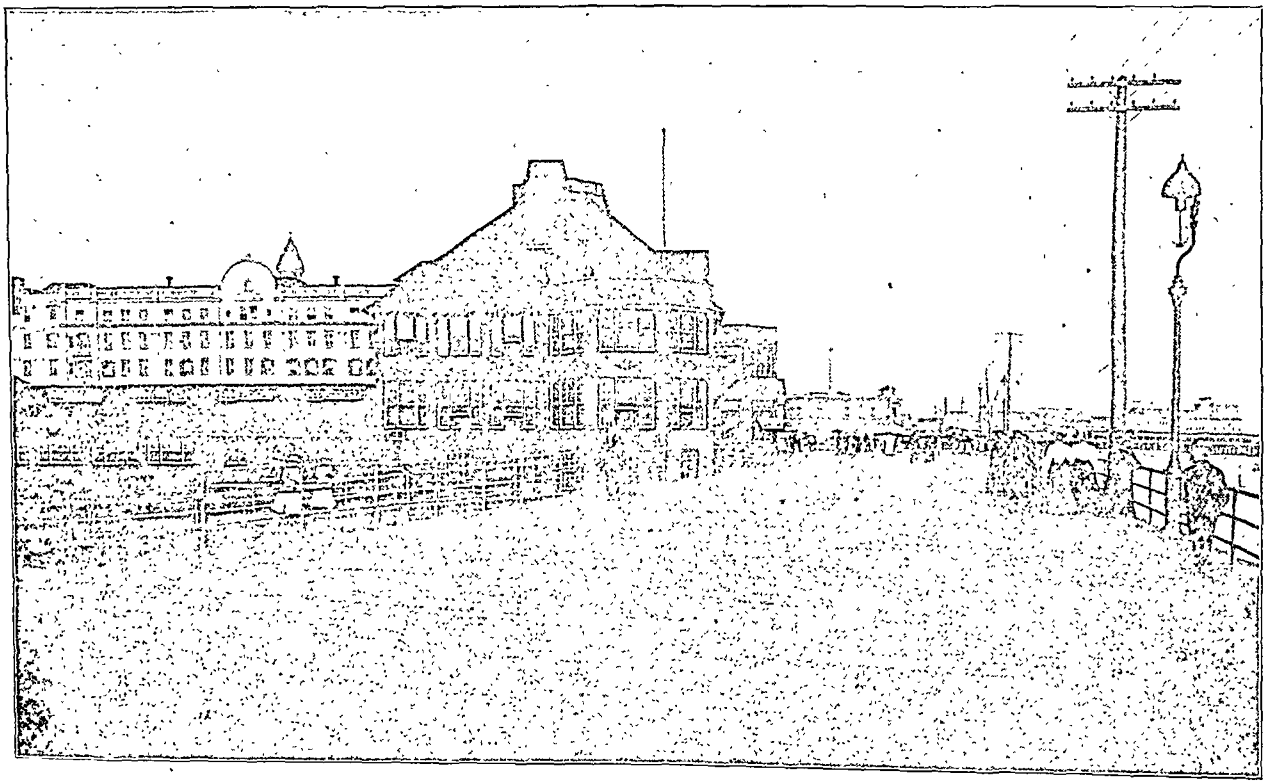
The visitor at this season need dread no discomfort, but rather look forward to all the comforts of home, doubly magnified. The rooms will be steam heated and electric lighted. He may bathe in salt sea water with the winter chill extracted, may read or dream before a glowing open-grate parlor fire, wander through tropical-like conservatories or bask in warm sunshine, and from behind the clear glass inclosures of the sun parlors watch the ocean in its moments of anger or placidity. He may breakfast, lunch and dine on the finest that the land affords, and, in short, live like a prince, with naught to annoy and everything to please and entertain.

Many of the more recent visitors to Atlantic City do not know that although the history of the place as a pleasure resort dates from the time of its founding in 1854, exactly fifty years ago, it was not until more than twenty years later that it became known as a health resort and sanitarium. To-day there is no northern winter resort so popular and none so urgently recommended by physicians as Atlantic City.

The fame of the resort is grounded not alone on those qualities which have established its pre-eminence as a summer resort, nor on those which give it prominence as a winter resort. It is a health resort, as well as a great seaside city, where, throughout the year, people from every state crowd its hotels and lounge on its famous Boardwalk.

Several elements combine to produce the tonic and resting effects of the Atlantic City air, chief of which is the presence of a large amount of ozone—the stimulating, vitalizing principle of the atmosphere. Ozone is a tonic—it strengthens the respiratory organs and helps the whole system. It follows naturally that the circulation is improved, tone is given to the stomach, the liver is excited into healthful action and the whole body feels the benefit.

For the man or woman who is brain-weary and breaking down under the weight of business, professional, social or domestic cares, there is no better restorative than a season of rest and recreation at Atlantic City. With increased bodily vigor comes the gentle ministration of tired Nature's sweet restorer. This is a sure sign that the nerves are being well rested.



Brighton Casino. Meeting Place for Section on Nervous and Mental Diseases.

Persons who could scarcely walk at home, after a few days' stay in Atlantic City, stroll long distances on the strand or Boardwalk, with only a cheerful sense of weariness that is soon succeeded by a sharpened appetite, the reward of agreeable exercise. Few, indeed, who visit this resort fail to experience a marked improvement in appetite.

THE HOTELS.

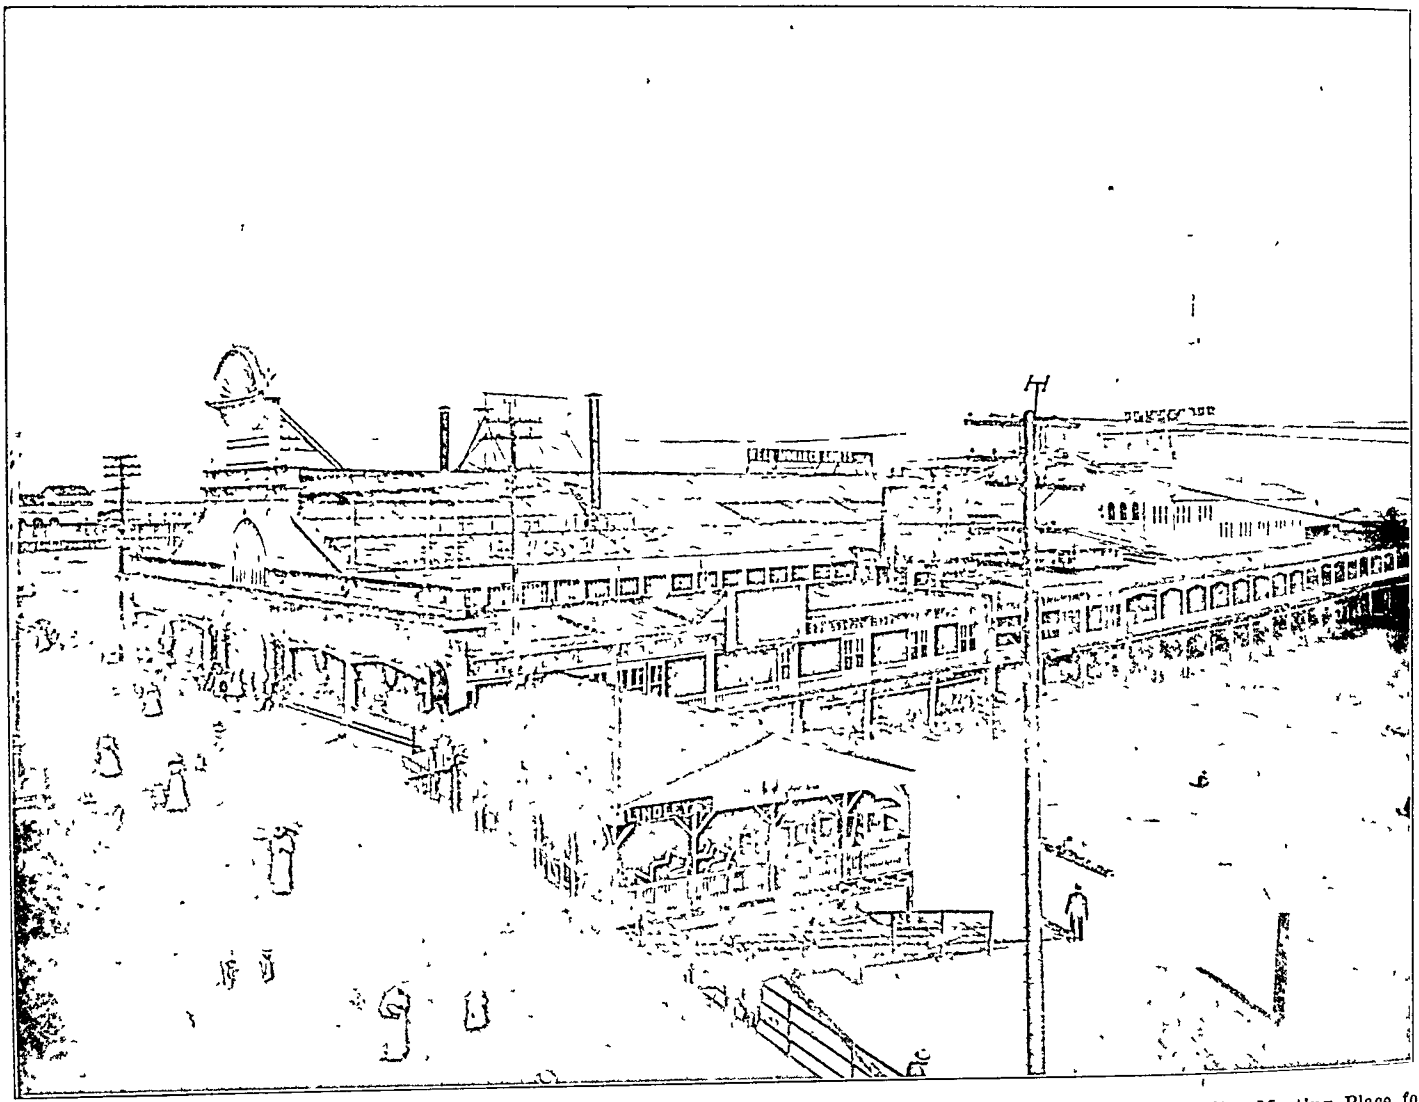
No city in the world has as many well-appointed hotels, in proportion to the population, as this great seaside resort. Beside the large number of first-class hotels, there are many more of the second class, and hundreds more of desirable boarding houses, where the rates are such as to astonish those who are accustomed to the extortionate charges at other resorts. Of these hotels and boarding houses—700 in all—too much can not be said. They range from the rivals of the finest in the world to the quiet, home-like boarding houses found in every large city. In point of equipment and inviting comfort they are unexcelled, and being almost without number, they stand to satisfy the vagaries of every applicant. Altogether, they will accommodate not less than 200,000 visitors. The Committee on Hotels makes the following report:

A LIST OF HOTELS AND PRICES.

Out of the many hotels the committee has selected the following, which they can recommend. Comfortable board may be obtained in Atlantic City from $1 per day upward. The minimum rates apply to single rooms without baths, while the per capita rate per day for double rooms in most cases can be slightly reduced when two occupy the same room. For those wishing accommodations on the European plan, the Dunlop and Young's Hotel are exclusively European; the Grand Atlantic, the Wiltshire, the Garden, the Islesworth, and the Rudolf. The prices given below cover the American plan, except those furnishing accommodations on either European or American plans, referring to the Dunlop and Young's Hotel.

RATES PER DAY ON AMERICAN PLAN.

Bouvier	$1.50	and up.	
Roxborough	1.50	to	$2 50
Revere	2.00	to	2 50
Altamont Craig Hall	2.00	to	3.00
Archdale	2.00	and up.	
Belmont	2.00	and up.	
Berkshire Inn	2.00	to	3 00
Chester Inn	2.00	to	2 50
Dunlop, $2 00 to $3.00, European exclusively.			
Young's Hotel, $2.00 to $3.00, European exclusively.			
New Hygeia	2 00	to	3 00
Albemarle	2.00	to	3 50
Arlington	2.00	to	3 50
Holmhurst	2.00	to	4.00
Champlain	2.00	to	4 00
Kenilworth Inn	2 00	to	4 00
Hotel Majestic	2.00	to	4.00
Hotel Boscobel	2.00	to	6 00
Chatham	2.50	to	3 00
Glaslyn	2.50	to	3 00
Hotel New England	$2.50	to	$3 00
Ponce de Leon	2.50		
Wiltshire (also European)	2.50	and up	
Hotel Imperial	2 50	to	3 50
Hotel Shoreham	2 50	to	3 50
Loraine	2 50	to	3.50
Rittenhouse	2 50	to	4.00
Grand Atlantic (also European)	2.50	to	5 00
Raleigh	3.00		
Hotel Gladstone	3 00	to	5 00
Hotel Savoy	3.00	to	5.00
Hotel Strand	3 00	to	5 00
Haddon Hall	3.00	to	7 00
Islesworth (also European)	3 00	to	8.00
Shelburne	3 00	to	8 00
Seaside	3 50	to	4.00
Rudolf (also European)	3 50	to	5 00
Garden	3 50	to	6 00
Hotel Dennis	3 50	to	6 00
Royal Palace	3 50	to	6 50
Hotel Windsor	3.50	to	7 00



Young's Ocean Pier. General Headquarters for Bureau of Registration, General Sessions and Scientific Exhibit. Meeting Place for Section on Diseases of Children.

Hotel Chelsea	$4.00	and up.	
St. Charles	4.00	and up.	
Hotel Traymore	4.00	to	$8.00
Hotel Brighton	4.00	to	10.00
Marlborough House	4.00	to	10.00

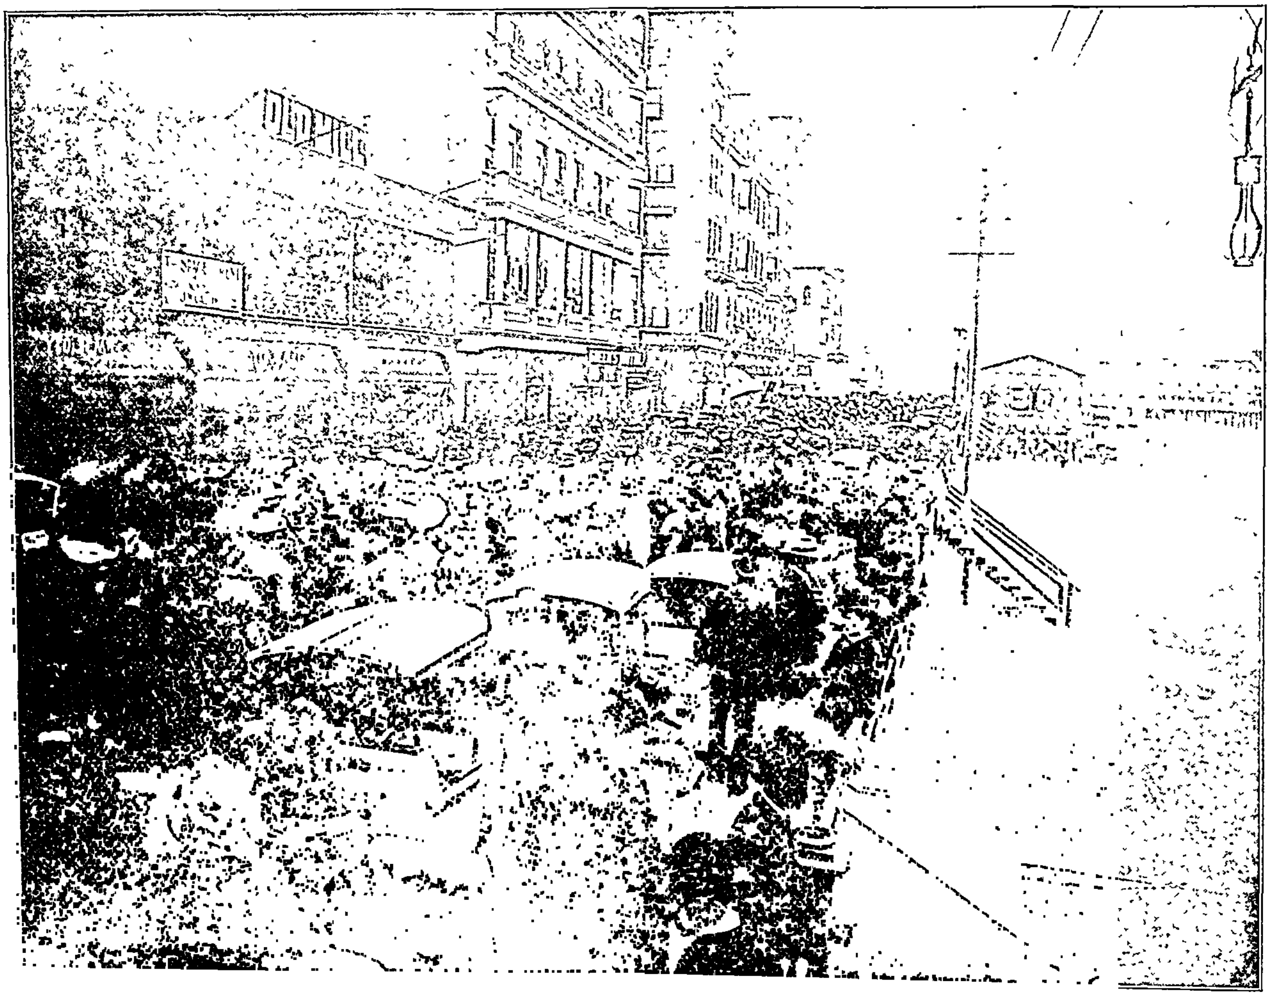
In order to get good accommodations, engagements for rooms should be made without delay. The committee will be glad to furnish any information desired, and will be pleased to engage quarters at the various hotels, or physicians may write to the hotel direct.

WM. EDGAR DARNALL,
Chairman Hotel Committee.

The rolling chairs for invalids and well people who are averse to walking on the Boardwalk, are a great convenience to the thousands of hotel guests. The elevators in the hotels start from the ground floor, and invalids may be wheeled in from the street to the elevator, thence to an upper balcony or to the bedroom, without leaving the chair.

Atlantic City is not a watering place in the sense that the term generally applies. It is, as has been stated, a seaside city, with a permanent population of about 35,000, and more than $75,000,000 of taxable property. All of the advantages of a well-organized municipality are offered, with the added attractions of a perfect health and pleasure resort. Well-paved streets, beautiful residences, a very efficient fire department and police force, over a score of churches, including all denominations, ample telegraph and telephone systems and connections, several steamship lines to adjoining resorts and other features might be mentioned as evidence of the attractions of the city.

In point of accessibility, Atlantic City possesses advantages unequaled by any other resort in America. It is connected with Philadelphia and with all the railroads centering there by numerous through trains, which make the run in sixty minutes, while with New York and the East there is ample communication by through trains, which make the run from New York to Atlantic City in three hours. From the West and South, passengers are conveyed via Philadelphia, across the Delaware River bridge, without change of cars.

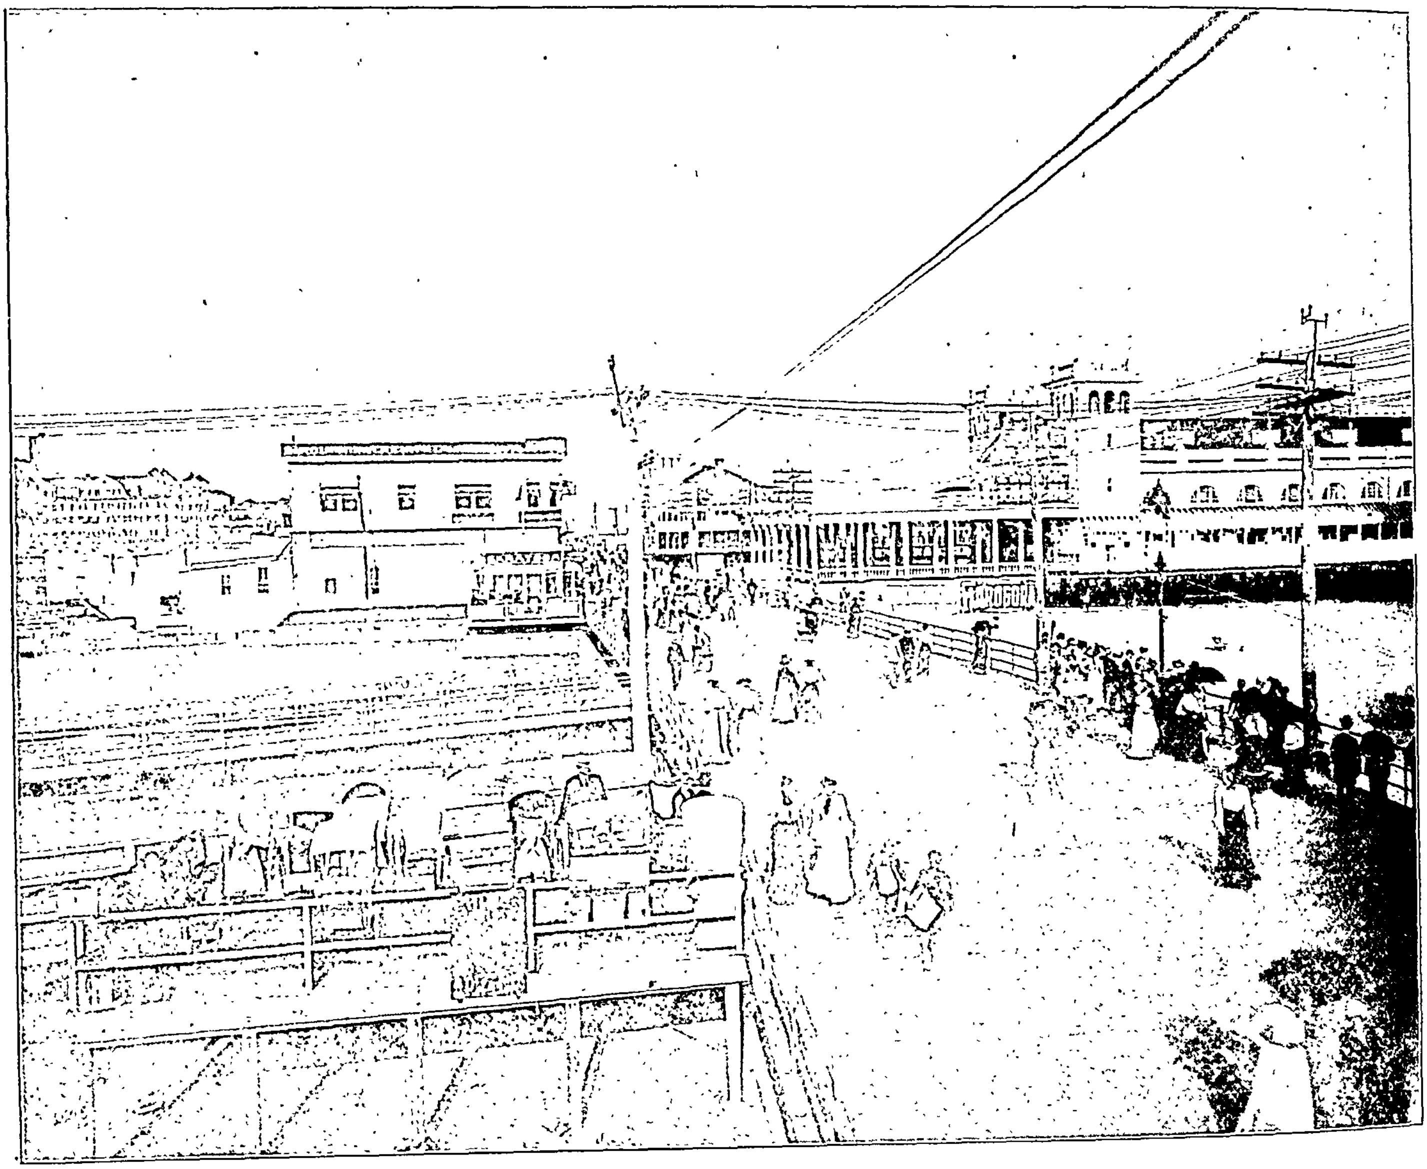


Showing the Easter Visitors (Easter Sunday, 1904).

Atlantic City long since learned how best to provide for the health and pleasure seeker, and it is now the business of the resort to set forth its varied attractions, which are all in the direction of making one's stay delightful. Hard to amuse, indeed, would be the visitor who could not find some congenial diversion ever close at hand, every day in the week and every week in the year. Atlantic City, indeed, is the nation's playground, its public park, its place of perennial pleasure. In the charms of novelty and ever-shifting variety it surpasses any other city in the East, the West, the North, or the South.

FISHING AND BOATING.

The water attractions of Atlantic City are unique. A fleet of yachts, unexcelled anywhere in the country, furnish sailing on the ocean's billows, calm and peaceful at times, and at other times as rough and as boisterous as one could wish; or, if one perfers, he can glide over the smooth waters of the bays and inlets, without the slightest danger of seasickness. Then there is the deep-sea fishing "outside," or what is more inviting to some, the sport of catching sea bass and weak fish "inside."



Showing Steel Pier in the distance. Steeple-chase Pier in the foreground.

THE GOLF LINKS.

One of the crowning features of Atlantic City's environs is the magnificent home of the Country Club, with its elegant golf grounds. The links have eighteen holes, overlooking Lake's Bay, and are in close proximity with a five-mile-wide meadow, where game is plentiful. In the picturesque distance the ocean and variegated horizon make a glorious silhouette to the east, while the western wildwood and evergreen pines give the surroundings a most delightful appearance.

BATHING.

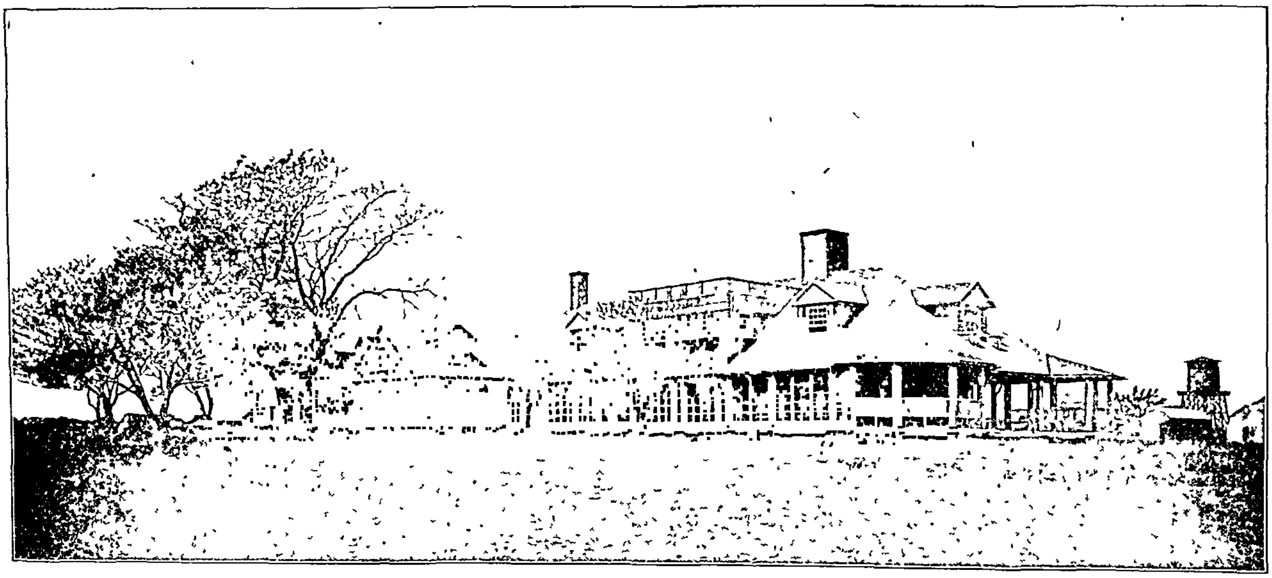
The pleasures of the surf bath bring multitudes to Atlantic City during the summer months, and bathing here attains a popularity unknown to more northern resorts. The near approach of the Gulf Stream to this point increases the temperature of the water to a delightful degree, and takes from it the bitter chill from which so many would-be bathers shrink. At the fashionable hours of bathing, from 11 to 1, the beach is crowded with thousands of merry bathers, whose shouts and laughter mingle with the roar of the surf. The bathing is superb, especially after the summer's sun has warmed the ocean to suit those who are averse to the first cold dip in springtime. The bathing is as safe here as anywhere in the world, and considering the many, many thousands who bathe annually, the drownings are very few.

Bathing at Atlantic City begins earlier and continues longer than at any other seaside resort along the eastern coast of the United States. The bathing beach—which is backed by the Boardwalk with its crowd of interested spectators—will accommodate a million people in comfort; some lying on the sand or strolling about; some wading in the shallows, and others swimming out boldly in the depths. This remarkable stretch of sand is free from stones or gravel, and is as nearly perfect as any bathing resort.

THE FAMOUS BOARDWALK.

The Boardwalk is the greatest promenade of its kind in the world; it is solidly built of steel and is forty feet wide. Bounded by a strong iron fence, it reaches from one end of the city front to the other, and will accommodate at one time more than a million persons without unpleasant crowding. The prominent hotels are situated close to it and are entered from it, while innumerable stores, bazaars, restaurants, curio shops, picture galleries and every sort of place of amusement that ingenuity can devise, make a kaleidoscopic picture that is seldom equaled.

The life, the light and the color that one sees on this promenade are indescribable. It is an endless dress parade—a grand review—in which everybody is one of the reviewers, as well as one of the reviewed. The animation, the overflowing good nature, the laughter and contagious hilarity of this restless throng are irresistible. The lights from the scores of bazaars, the buoyant merriment of the children, the soft, melting colors of the summer dresses of the women, the freshened loveliness of the women themselves, and the thousand and one little scraps of life and tone that line the thoroughfare, all blend in a picture that is warranted to banquet the eye and rest the mind of anyone who is not utterly lost to every sense of enjoyment.



Atlantic City Country Club at Northfield. May be reached by trolley.

Nowhere in the world is there such a kaleidoscope of beauty, such a panorama of wonders, as one sees on this great ocean promenade. An annual visitor said: "I have been to every prominent seaside resort and spa in Europe, and I know whereof I speak when I say that nowhere is there a resort that can in any way approach Atlantic City. In addition to the unusual opportunities for enjoyment, it is unquestionably the healthiest place in America."

From this Boardwalk there extend out into the sea several piers, on which are pavilions and theaters. All day long something is happening here for the enjoyment of the thousands of visitors. Concerts of high excellence are given by bands of music, and amusements of varied sorts are taking place in profusion. One of these piers is a steel pier, which extends 2,800 feet into the ocean.

THE PLACES OF MEETING.

Some of the sessions of the American Medical Association will be held in the Marine Hall, an immense auditorium on this steel pier directly over the ocean. Delegates, while considering the important matters pertaining to the convention, and hearing what others have to say, may also listen to what the wild waves are saying the whole day long, meantime inhaling life-giving ozone at every breath. Young's pier is a short distance away, and in its immense shore-end pavilion are to be located the meeting places of several sections, as well as the Registration Bureau, the Scientific Exhibit and the Drug and Instrument Exhibit. A list of the various meeting places follows:

MEETING PLACES.

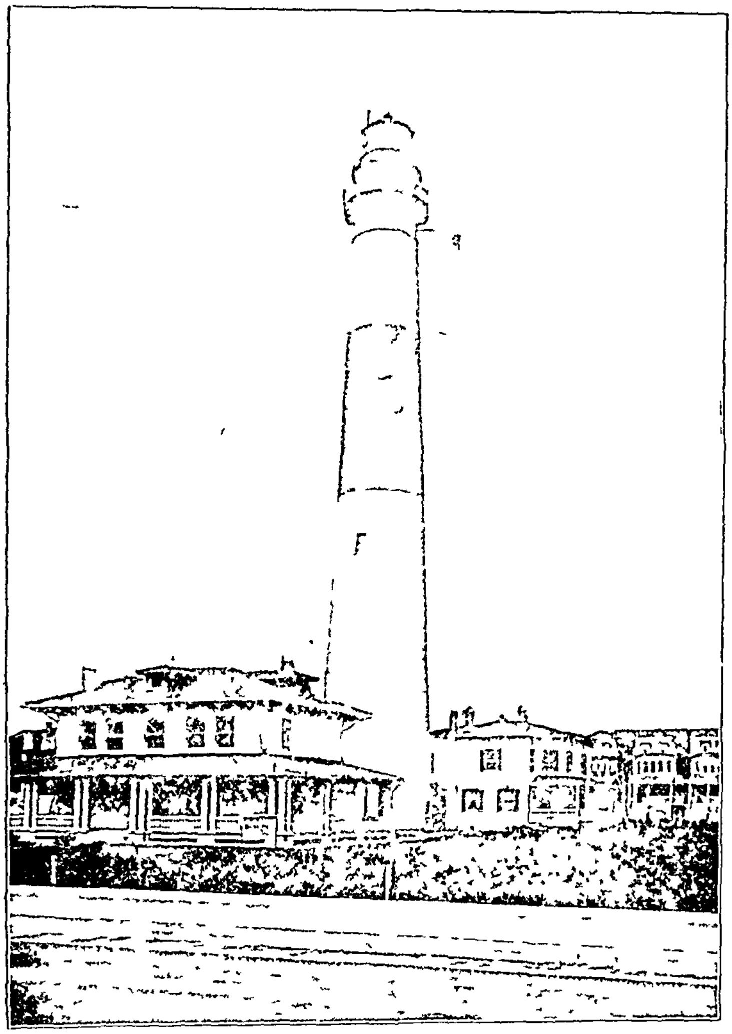
General Sessions	Young's Pier.
Registration Bureau	Young's Pier.
Practice of Medicine	Young's Pier.
Scientific Exhibit	Young's Pier.
Diseases of Children	Young's Pier.
Surgery and Anatomy	Steel Pier.
Ophthalmology	Steel Pier.
Obstetrics and Diseases of Women	Steel Pier.
Laryngology and Otology	Steel Pier.
Hygiene and Sanitary Science	Garden Hotel.
Stomatology	Islesworth Hotel.
Nervous and Mental Disease	Brighton Casino.
Cutaneous Medicine and Surgery	Shelburne Hotel.
Materia Medica, Pharmacy and Therapeutics	Young's Hotel.
Pathology and Physiology	Green's Hotel.
House of Delegates	High School.

HEADQUARTERS OF THE SECTION OFFICERS.

The following hotels are the general headquarters of the various sections. The Marlborough House is the general headquarters of the American Medical Association:

Practice of Medicine	Traymore and Gooden.
Obstetrics and Diseases of Women	St. Charles.
Surgery and Anatomy	Haddon Hall and Islesworth.
Hygiene and Sanitary Science	Gooden.
Ophthalmology	Seaside.
Diseases of Children	Dennis.
Stomatology	Islesworth
Nervous and Mental Diseases	Brighton.
Cutaneous Medicine and Surgery	Shelburne.
Laryngology and Otology	Strand.
Materia Medica, Pharmacy and Therapeutics	Young's.
Pathology and Physiology	Windsor.

It must not be supposed that all the enjoyment, all the recreation, all the benefits of a visit to Atlantic City are confined to the summer months. The witching charms of autumn sea and sky, hold many a summer visitor even until the ides of November. Indeed, not a few linger until December, and ere the holiday festivities are fairly over at home, the first company of winter visitors has arrived, harbingers of that larger company whose appearance marks the advent of February.



The Absecon Light

The "season" in Atlantic City, the reader will infer, continues throughout the year. The perennial visitor finds here, forsooth, an ever-changing but never-ending season. The resort's response to Spring's passionate wooing is a simple invitation to "come." In the springtime, particularly in March and April, the devotees of Dame Fashion, banishing all desire for social pleasure at home, hasten to Atlantic City to enjoy new pleasures and new life amid old friends and old scenes.

In summer time the joys of other days are forgotten Life, animation and happiness go hand in hand, and pleasures abound on every side. The spell is irresistible; the charm contagious.

When mellow autumn comes and the year puts on her visionary tints, Atlantic City again bids you "come." The air is pregnant with health and the breezes are a tonic to mind and body. It is even said that the sunshine of October intoxicates with excessive healthfulness. At this season there is a tranquillity unknown to summer visitors. The sea of human faces has ebbed, and there is relief in the absence of the surging, ever-changing crowds of summer time.

Sun parlors, pavilions, rolling chairs and carriage drives along the glittering strand or over the stone roads—these and other pastimes appeal to the easy-going, pleasure-loving visitors. The bathing in September and October is delightful, and the fishing, crabbing and boating are at their best.

Sufferers from autumnal catarrh, a form of hay fever, enjoy great relief in Atlantic City. Delicate people and those susceptible to the malarial and typhoid influence of the autumn also enjoy immunity from these affections in Atlantic City.

To the well, during the fall months, there is little attempt at indoor pleasure in daytime—at least not until November. Even the card tables are deserted for the rod, the gun or the sail, and those who are not experts with these traverse the beach and Boardwalk in quest of other forms of pleasure.

In the heart of winter social life plays a great rôle. The amusements consist chiefly of musicales, theatricals, dances, receptions, card parties, readings, lectures and a round of gayeties at the hotels and cottages.

Thus the days, the seasons and the years come and go. Every day has its pleasures, every season its charms and every year its changes. As "Queen of the Coast," Atlantic City worthily wears her crown.

Nowhere else in America is there such magnitude of relaxation. Day after day, from early morn to midnight, it presents itself along that riparian plaisance, the Boardwalk. Nowhere else do the social extremes come nearer to touching each other without friction or unpleasant lines of demarcation.

The "season" at Atlantic City, as we have seen, does not end with the close of the Lenten and post-Lenten pastimes, nor with the recession of the summer procession. In truth, the "season" at Atlantic City, as has been stated, never ends. The year begins with the midwinter season, which imperceptibly blends into the Lenten season, which blossoms into the brilliant Easter season, which runs on to the regular spring season, which is a prelude to the midsummer season, which is followed by the late summer and early fall season, which gives way to the regular autumn season, which brings us to the holiday season, which makes both ends meet by linking on to the midwinter season.

OTHER MEETINGS AT ATLANTIC CITY.

As is customary, several of the specialists' societies are to meet in Atlantic City just before or just after the session of the American Medical Association. These are mentioned in another column in the list of "Coming Meetings," under the heading of "Society Proceedings." Among others is the American Academy of Medicine, which will hold its twenty-ninth session. This organization will take up the reports of committees on the National Bureau of Medicine and Foods, on the teaching of hygiene in the public schools, and on medical education.

The next session of the Association of American Medical Colleges will be held in Atlantic City, Monday, June 6. At the educational session at 10 a. m., to which visitors are invited, there will be the following program:

President's Address. J. R. Guthrie, Dubuque, Iowa.

Under What Conditions Should a Medical College Give a Student Advanced Standing? William H. Wathen, Louisville, Ky.

What Credit, If Any, Should Be Given by Medical Colleges to Holders of Baccalaureate Degrees? Mr. Henry L. Taylor, Albany, N. Y.

A Plea for Uniform Curricula in Medical Colleges. George M Kober, Washington, D. C.

This program is preliminary, and other papers may be added.

At 2:30 Monday afternoon the business meeting will be held. The secretary-treasurer of the association is Dr. Fred C. Zapffe, 1764 Lexington Street, Chicago. The dean of each college holding membership in the association is its accredited representative at this meeting. Representatives other than the dean must present signed credentials. Each college is entitled to one representative.

RAILROAD RATES.

The prospect of a large attendance at Atlantic City, one which will, perhaps, be the largest of any session the American Medical Association has yet held, depends on two facts. The profession was never so well organized as at present, and the railroad rates have never been so favorable. The low rate, combined with the nearness of Atlantic City to the large cities of the East, where the American Medical Association has so many members, make the prospects very bright for this session.

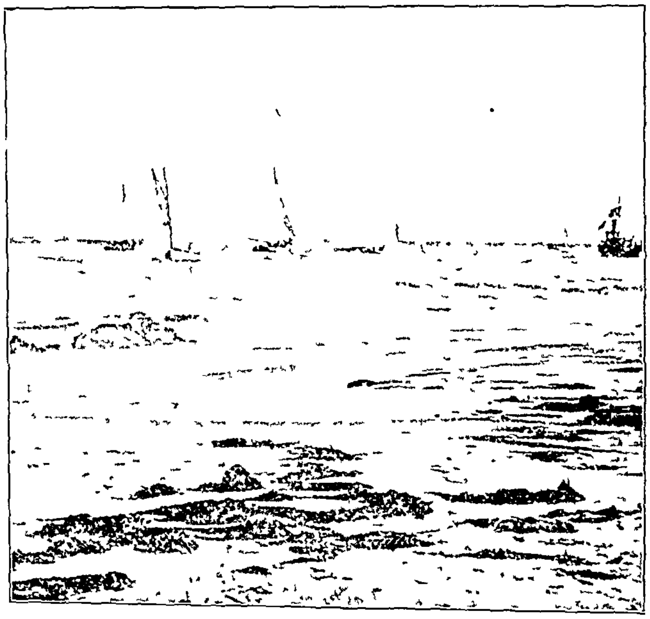
The Trunk Line Association has granted a rate of one fare plus $1.00 for the round trip, except within 100 miles of Atlantic City. Within the 100-mile radius the regular excursion fare will apply. The tickets are to be for continuous passage and must be deposited with the joint agent on arrival at Atlantic City for his indorsement, but on returning, stop-overs will be allowed at Philadelphia, Washington and Baltimore. These tickets will be sold and will be good for passage June 1, 2, 3, 5 and 6, and will be good for return leaving Atlantic City June 4 to 13, inclusive.

The Central Passenger Association has granted the same rates The Western Passenger Association has granted a rate of one fare plus $2.00 for the round trip, tickets on sale June 1 to 4, and good returning till June 13, with privilege of extension under certain conditions. Stop-overs will be granted as above. Information from other passenger associations indicates that most of them will grant similar rates.

SPECIAL TRAINS AND EXCURSIONS.

As is usual, various trains will be run through various parts of the country; Iowa, Missouri, the Northwest and some parts of the South will have their special trains. At least one special will be run from Chicago over the Pennsylvania System, and will leave Chicago Sunday, June 5, at 2 p. m. There will probably be at least two sections, as many western parties will arrange to take this train. This will be an elaborately fitted and complete train, and a most enjoyable time may be expected by the travelers.

A number of excursions can be arranged from Atlantic City, others from New York City, following the session. Large delegations are expected to stop in Philadelphia, both before and after the meeting, to attend the clinics. In this issue will be found a complete schedule of these clinics that have been arranged for the members of the Association in Philadelphia.



The Beach Toward the Inlet.

Another event is the unveiling of the Rush Monument, in Washington, Friday afternoon, June 10. Members of the Association will go in a body to witness this long-looked-for event.

ENTERTAINMENTS.

Atlantic City is a most delightful place in its social life. Those who attended the last session need no reassurance as to the prospect of an enjoyable time socially. The local committee on entertainment is preparing various enjoyable functions, and will give special attention to the events for the wives and other ladies who accompany the members, so that the time shall pass pleasantly for them while the physicians are engaged in the scientific work of the meeting.

ATLANTIC CITY COMMITTEES.

The experience gained in the session of 1900—which was held at Atlantic City—has been of great value to the local committees in charge of the arrangements for this year. They report that matters are well in hand, and that affairs are working smoothly. The efficient local Committee of Arrangements consists of Dr. B. C. Pennington, chairman; Dr. J. A. Joy, treasurer; Dr. E. A. Reilly, registrar; Dr. Philip Marvel, secretary.

The special committees whose active chairmen are looking after the details assigned to their respective departments are:

Dr. W. Blair Stewart, Finance.
Dr. Walter Reynolds, Halls and Meeting Places
Dr. E. A. Reilly, Registration.
Dr. A. D. Cuskaden, Exhibits.
Dr. Theo. Senseman, Entertainments.
Dr. E. C. Chew, Bureau of Information
Dr. Emery Marvel, Banquets
Dr. Edward Guion, Printing.
Dr. W. E. Darnall, Hotels.
Dr. Joseph F. DeSilver, Badges, etc.
Dr. W. P. Conaway, New Membership
Dr. J. M. Marshall, Transportation.

RUSH MONUMENT DEDICATION.

DESCRIPTION OF THE STATUE AND THE MONUMENT THAT ARE TO COMMEMORATE THE LIFE AND WORK OF THIS GREAT PHYSICIAN.

We reproduce this week illustrations[1] of the Rush Monument, which is to be dedicated at Washington, D. C., on the afternoon of Friday, June 10. Definite arrangements have not yet been made, but it is probable that a special train or trains will be run from Atlantic City to Washington for the accommodation of the members.

The illustrations show the general character of the monument. Dr. Rush is represented in a walking attitude, with paper and pen in his hand, apparently lost in thought. The general scheme is a simple one, and carries out the old idea of representing the subject as a full standing figure, on a pedestal somewhat higher, the whole resting on a base of three steps. To give this old idea any originality was difficult, but the architect has treated the subject in a particularly striking way by making the entire pedestal circular, something seldom attempted, and by treating the moldings and the decoration in the style of Louis XVI; in other words, in that time in which Dr. Rush flourished, and by the addition of three small bas-reliefs commemorating Dr Rush's career as a physician, patriot and writer.

The choice of materials has been carefully made—the finest kind of bronze for the statue, the best Indiana limestone for the pedestal and pink granite for the steps. The base consists of three granite platforms the lower one being 12 feet 9 inches across. Surmounting these steps is a pedestal consisting of the base, die and cap of hard Indiana limestone, the total height being 10 feet 4 inches. The base of the die is 4 feet 10 inches across. The height of the figure is 7 feet 6 inches

The Statue of Dr. Benjamin Rush

---

[1] Through the failure of the engravers to supply us the half tone illustration of the monument in its completeness we are compelled to omit it. It will appear next week

inches, and the plinth or base is 4 inches, making the total height of the statue alone 7 feet 10 inches.

The inscriptions, in gilt bronze, are as follows:

On the front panel: "Benjamin Rush, 1745-1813. Physician and Philanthropist."

On the right panel: "The First American Alienist."

On the left panel: "Signer of the Declaration of Independence."

On the rear panel: "Studium sine calamo somnium."[1]

The monument is being erected on the site originally designed by the Secretary of the Navy, on the elevation in the park opposite the U. S. Naval Museum of Hygiene and Medical School. The ground was broken for the pedestal March 23. The architect is Mr. Lewis R. Metcalfe, New York; the sculptor, Mr. R. Hinton Perry, and the bronze founders, the Henry-Bonnard Bronze Co., New York.

The present Rush Monument Committee consists of J. C. Wilson, M.D., Philadelphia; H. D. Holton, M.D., Brattleboro, Vt.; Frank Billings, M.D., Chicago; L. Duncan Bulkley, M.D., New York, and W. L. Rodman, M.D., Philadelphia.

The oration at the dedication will be delivered by Dr. J. C. Wilson, Philadelphia.

---

[1] The Latin phrase was a favorite of Rush's, who used it in reference to his habit of making annotations as he read.

ASSOCIATION NEWS

OFFICIAL CALL.

The Fifty-Fifth Annual Session of the American Medical Association, To Be Held in Atlantic City,
June 7-10, 1904.

To the Members of the American Medical Association, and to Constituent State Associations:

The next annual session of the American Medical Association will be held at Atlantic City, New Jersey, on Tuesday, Wednesday, Thursday and Friday, June 7, 8, 9 and 10, 1904. The first general meeting, which constitutes the opening exercises of the scientific functions of the Association, will be held at 10 a. m., Tuesday, June 7.

The Registration Department will be open from 8 a. m. to 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, June 6, 7, 8 and 9, and from 9 to 11 a. m. on Friday, June 10.

NEW MEMBERS.

Those who join the Association at its annual session must present certificates of membership in good standing in their state association or in one of its affiliated branches.

THE HOUSE OF DELEGATES.

The House of Delegates of the American Medical Association will convene at the High School Building, Atlantic City, New Jersey, at 10 a. m., Monday, June 6, 1904. Each constituent state and territorial association is entitled to one representative for each 500 of its resident regular members, or fraction thereof. "State associations or societies in counting members for a basis of delegate representation in this House shall count only members in good standing, who pay regular dues to the state association, either directly or indirectly through county societies."

"Members of the House of Delegates shall be elected for a term of two years, and those state and territorial associations entitled to more than one representative are requested so to arrange such elections that one-half of their delegates, as near as may be, shall be elected each year." (Chap. III, Sec. 4, By-Laws.)

George H. Simmons,
Secretary.

Frank Billings,
President.

THE OFFICIAL PROGRAM.

In order to avoid misunderstandings and to protect the interests of advertisers, attention is called to the fact that there is but one official program. This program is copyrighted by the Board of Trustees and contains no advertising matter. It will not be distributed until the week of the session.

MEETING OF COMMITTEE ON MEDICAL LEGISLATION.

A meeting of the National Auxiliary Congressional and Legislation Committee will be held at 2:30 p. m., Wednesday, June 8, at the High School Building, Atlantic City, according to the call issued by the chairman, Dr. Charles A. L. Reed, Cincinnati.

ASSOCIATION COMMITTEES.

List of Standing Committees of the Association and their Chairmen and Members.

Following is a list of the standing committees of the Association:

Committee on Award of Association Medal.—Lewis S. McMurtry. Louisville, Ky., chairman; Burnside Foster, St. Paul, Minn.; M H. Fussell, Philadelphia.

Committee on Award of Senn Medal.—James H. Dunn, Minneapolis, chairman; M. L. Harris, Chicago; Floyd W. McRae, Atlanta, Ga.

Committee on Scientific Exhibit.—F. B. Wynn, Indianapolis, chairman.

Committee on Scientific Research.—Alfred Stengel, Philadelphia, chairman; William Osler, Baltimore, and L. Hektoen, Chicago.

Committee on Organization.—J. N. McCormack, Bowling Green, Ky., chairman; P. Maxwell Foshay, Chicago; George H. Simmonds, Chicago.

Committee on Rush Monument.—James C. Wilson, Philadelphia, chairman; Henry D. Holton, Brattleboro, Vt., treasurer; Frank Billings, Chicago; L. Duncan Bulkley, New York; Wm. L. Rodman, Philadelphia.

Committee on National Legislaton.—Charles A. L. Reed, Cincinnati, Ohio, chairman, one year; W. L. Rodman, Philadelphia, two years, and William H. Welch, Baltimore, three years.

Committee on Business.—Edwin Walker, Evansville, Ind.; A. R. Craig, Columbia, Pa.; George M. Kober, Washington, D. C.; T. J. Murray, Butte, Mont., and William Davis, St. Paul, Minn.

Committee on Transportation and Place of Session.—M. L. Harris, Chicago; F. H. Wiggin, New York; H. Bert Ellis, Los Angeles, Cal.; B. H. Hartwell, Ayer, Mass.; G. C. Savage, Nashville, Tenn.; H. A. West (deceased), Galveston, Texas, and A. F. Jonas, Omaha.

Committee on Major Walter Reed Monument.—W. W. Keen, Philadelphia, chairman; Joseph D. Bryant, New York City; A. T. Cabot, Boston; Victor C. Vaughan, Ann Arbor, Mich.; T. S. Cullen, Baltimore, and Frank Billings, Chicago.

Committee on Reapportionment.—William S. Foster, Pittsburg, chairman; P. Maxwell Foshay, Chicago; J. N. Hall, Denver, President-elect and Secretary ex officio.

Committee on National Incorporation.—Joseph D. Bryant, chairman, New York; H. L. E. Johnson, Washington, D. C.; Leartus Connor, Detroit; D. S. Fairchild, Des Moines, Iowa, and C. G. Kenyon, San Francisco.

Committee on Reciprocity.—W. L. Rodman, Philadelphia, chairman; William H. Welch, Baltimore; Joseph M. Mathews, Louisville, Ky.; Henry Beates, Jr., Philadelphia; T. J. Murray, Butte, Mont.

Committee on Public Health.—Herman Spaulding, Chicago, chairman; J. N. Hurty, Indianapolis; W. H. Sanders, Mobile, Ala.; H. A. West (deceased), Galveston, Texas; W. C. Gorgas, U. S. A.; V. C. Vaughan, Ann Arbor, Mich.

Committee on Prophylaxis of Venereal Diseases.—Henry D. Holton, Brattleboro, Vt., chairman; George M. Kober, Washington, D. C.; W. H. Sanders, Mobile, Ala.; Ludwig Weiss, New York, secretary; L. D. Bulkley, New York; Louis E. Schmidt, Chicago.

Committee on Credentials and Registration.—George H. Simmons, Chicago, chairman; P. Maxwell Foshay, Chicago; H. O. Walker, Detroit.

ORGANIZATION MEETING AT ATLANTIC CITY.

A Conference of Councilors and State Association Officers to be Held to Discuss the Subject of Organization.

The suggestion for a conference of councilors and secretaries of state associations and others interested during the coming session of the Association at Atlantic City has been received with so much favor in all sections of the country that the meeting has been decided on, and the program is now being arranged. It is proposed that the proceedings shall begin with ten-minute papers from experienced workers in organization work, and these to be followed by a general discussion involving a comparison of views and experiences.

The time and place of the meeting will be announced later in The Journal, as well as in the official program. The meeting will be arranged so as to interfere to the least possible extent with the meetings of the sections and of the House of Delegates. The meeting will be especially for councilors and secretaries of state societies, but all who are interested in the work of organization will be cordially invited to attend the conference and to take part in the proceedings.

THE SECTION PROGRAMS

Of the Fifty-Fifth Annual Session of the American Medical Association at Atlantic City, June 7-10, 1904.

The following is a list of titles of papers to be read before the various sections at the coming session of the American Medical Association. The order in which the titles are printed here will not necessarily be followed in the official program. If there are any corrections to be made, write immediately to the secretary of the section and not to The Journal.

Section on Practice of Medicine.

Chairman, Alexander Lambert, New York City; Secretary, J. L. Miller, 100 State Street, Chicago.

Chairman's Address: The Adaptation of Pure Science to Medicine. Alexander Lambert, New York City.

Pernicious Anemia and Its Relation to Gastric Digestion, Based on Twenty-five Cases. Chas. G. Stockton, Buffalo, N. Y.

Diagnosis and Treatment of Perforation in Typhoid Fever. Morris Manges, New York City.

A Case of Typhoid Fever with an Unusual Complication. William E. Darnall, Atlantic City, N. J.

Mortality and Management of Pneumonia. Edward F. Wells, Chicago.

The Study of a Series of Cases of Pneumonia, with Special Reference to Diagnosis and Complications. Joseph Sailer, Philadelphia.

Appendicitis from the Standpoint of the Physician. S. G. Bonney, Denver.

Has Influenza Been a Causative Factor in the Increase of Appendicitis? Philip Marvel, Atlantic City, N. J.

SYMPOSIUM ON ARTERIOSCLEROSIS.

Pathology of Arteriosclerosis. William H. Welch, Baltimore.

Arteriosclerosis from Acute Infectious Diseases. W. S. Thayer, Baltimore.

Arteriosclerosis of Syphilitic Origin. C. Travis Drennen, Hot Springs, Ark.

Arteriosclerosis of Nephritic Origin. George Dock, Ann Arbor, Mich.

Arteriosclerosis Due to Metallic Poisons. Frank Billings, Chicago.

Arteriosclerosis of Alcoholic Origin. Richard Cabot, Boston.

Arteriosclerosis and Angina Pectoris. William Osler, Baltimore.

Treatment of Arteriosclerosis. James Anders, Philadelphia.

Aneurism of the Innominate Aorta. A. P. Francine, Philadelphia.

A Study of One Hundred and Eighty-six Cases of Mitral and Tricuspid Stenosis. Judson Daland, and E. L. McDaniel, Philadelphia.

Pleural Effusion in Heart Disease. J. Dutton Steele, Philadelphia.

Prolonged Delirium in Pericarditis and Endocarditis, with Report of a Case. E. M. Green, Easton, Pa.

Limitations of Digitalis in Heart Disease. Frank Jones, Memphis, Tenn.

Treatment of Cardiac Disease by Means of the Pneumatic Cabinet. Charles E. Quimby, New York City.

SYMPOSIUM ON GALL-BLADDER DISEASE.

Etiology of Cholecystitis and Cholelithiasis. Walter L. Bierring, Iowa City, Iowa.

Relation of Cholelithiasis to Diseases of the Pancreas. Eugene L. Opie.

The Relation of Disease of the Gall Bladder and Bile Ducts to Disorders of the Stomach and Intestines. Bertram W. Sippy, Chicago.

Diagnosis of Cholecystitis and Cholelithiasis. Joseph A. Blake, New York City.

Treatment of Cholecystitis and Cholelithiasis. Lucius W. Hotchkiss, New York City.

Ergot in General Practice. Alfred T. Livingston, Jamestown, N. Y.

Differential Leucocyte Count as an Aid in the Diagnosis of Fevers. William Krauss, Memphis, Tenn.

Pathogenesis of Uremic and Eclamptic Convulsions. Robert N. Willson, Philadelphia.

Amebic Dysentery; Its Local Lesions and Treatment. James P. Tuttle, New York City.

The Administration of Pancreas Muscle and Pancreas Liver Extracts in Diabetic Glycosuria. A. C. Croftan, Chicago.

Exophthalmic Goiter, Mitral Regurgitation, Bright's Disease and Retinitis Occurring Simultaneously in the Same Individual. Problem of Correlation. Arthur R. Elliott, Chicago.

Suicide; Some Instructive Cases. John L. Davis, Cincinnati.

SYMPOSIUM ON ARTHRITIS DEFORMANS.

Pathology and Etiology of Arthritis Deformans. Thomas McCrae, Baltimore.

Symptomatology of Arthritis Deformans. J. J. Walsh, New York City.

Treatment of Arthritis Deformans. Clarence E. Skinner, New Haven, Conn.

How the General Practitioner Should Treat Gonorrhea. Ferd. C. Valentine, New York City.

Problems for the Tuberculous Convalescent. A. Mansfield Holmes, Denver.

The Family Physician as a Factor in the Solution of the Tuberculosis Problem. S. A. Knopf, New York City.

Section on Obstetrics and Diseases of Women.

Chairman, L. H. Dunning, Indianapolis; Secretary, C. L. Bonifield, 432 West Fourth Street, Cincinnati.

Chairman's Address: Last Year's Progress in Gynecology. Senile Endometritis. L. H. Dunning, Indianapolis.

Further Experience in the Use of the Electrothermic Clamps in the Treatment of Cancer of the Uterus. Charles P. Noble, Philadelphia.

Primary Chorioepithelioma Malignum Outside of the Placental Site. Palmer Findley, Chicago.

The Technic of Wounds Incident to Laparotomy. H. O. Marcy, Boston.

Occipito-Posterior Position. J. M. Duff, Pittsburg.

Diagnosis and Treatment of Pelvic Deformity. George Boyd, Philadelphia.

Heart Disease as an Obstetric Complication. C. S. Bacon, Chicago.

The Obstetrician as a Specialist. J. B. DeLee, Chicago.

Comparative Value of the Different Methods for Accouchement Forcé. Gustav Zinke, Cincinnati.

Is Cesarean Section a Rational Method of Treatment in Placenta Previa? J. F. Moran, Washington, D. C.

A New Method of Determining the Size of the Conjugate Vera by Direct Measurement. W. Frank Haehnlen, Philadelphia.

The Propriety, Indications and Methods for the Termination of Pregnancy. Frank A. Higgins, Boston.

The Influence of Ovarian Implantation on Menstruation in Women. A. Palmer Dudley, New York City.

Repair of Pelvic Floor Lacerations. James H. Burtenshaw, New York City.

The Etiology and Pathology of Cystocele, with a New Operation for Its Relief. J. Riddle Goffe, New York City.

Primary and Secondary Repair of Injuries to the Anterior Vaginal Wall in Labor. B. C. Hirst, Philadelphia.

Injury to the Rectum in the Gynecologic Examination. Howard A. Kelly, Baltimore.

Treatment of Complete Uterine and Vaginal Prolapse. F. H. Wiggin, New York City.

The Advantages and Disadvantages of the Various Surgical Procedures for Relief of Retrodisplacements. E. E. Montgomery, Philadelphia.

Operations for Retroversion of the Uterus, with Special Reference to Effect on Subsequent Pregnancies. Franklin Martin, Chicago.

Two Cases of Retention of Urine Due to Retrodisplacement of the Gravid Uterus. Reuben Peterson, Ann Arbor, Mich.

Malformation of the Placenta. Henry F. Lewis, Chicago.

The Disease and Injuries Following Childbirth and Their Prevention. Edward J. Ill, Newark, N. J.

The Surgical Treatment of Bilocular Uterus and Bifid Vagina. H. W. Longyear, Detroit.

Postoperative Phlebitis of Femoral Veins. A. H. Cordier, Kansas City, Mo.

Clinical Experience with the Appendiculo-Ovarian Ligament. Daniel H. Craig, Boston.

Some Cases of Ectopic Gestation with Atypical Symptoms. Walter B. Dorsett, St. Louis.

A Plea for More Thorough Examinations of Doubtful Specimens of Ectopic Pregnancy. J. Wesley Bovée, Washington, D. C.

A Plea for Conservative Operations on the Ovaries from a Neurotic Standpoint, with a Report of Cases. J. W. Cokenower, Des Moines, Iowa.

Management of the Acute Infective Stages of Abdominal Inflammation. George Erety Shoemaker, Philadelphia.

Multiple Abscesses of the Omentum Following Grave Septic Peritonitis. Report of Two Cases. Hugo O. Pantzer, Indianapolis.

The Use of the Stem Pessary for Scanty and Painful Menstruation. J. H. Carstens, Detroit.

A Series of Mistaken Gynecologic Diagnoses. T. S. Cullen, Baltimore.

Membranous Endometritis. F. F. Lawrence, Columbus, O.

Malignancy of Ovarian Tumors. E. W. Cushing, Boston.

The Invasion of Carcinoma of the Uterine Cervix into the Surrounding Tissues. John A. Sampson, Baltimore.

The Prevention and Treatment of Postpartum Hemorrhage. Edward P. Davis, Philadelphia.

Section on Surgery and Anatomy.

Chairman, Charles A. Powers, Denver; Secretary, E. Wyllys Andrews, 100 State Street, Chicago.

Chairman's Address. Charles A. Powers, Denver.

Rupture of Mesenteric Glands During Typhoid Fever Simulating Intestinal Perforation; Report of a Case, with Operation and Recovery. Robert G. Le Conte, Philadelphia.

SYMPOSIUM ON APPENDICITIS.

Factors in the Mortality of Appendicitis. John B. Deaver, Philadelphia.

Appendicitis in Children. A. J. McCosh, New York City.

Papilloma of Appendix. N. B. Carson, St. Louis.

The Diagnosis of Appendicitis. Should the Appendix Be Removed when the Abdomen Is Opened for Other Conditions? Floyd W. McRae, Atlanta, Ga.

The Surgical Treatment of Gastroptosis. R. C. Coffey, Portland, Ore.

Excision of the Ileum. J. Shelton Horsley, El Paso, Texas.

Experimental Research on the McGraw Elastic Ligature. J. W. Draper Maury, New York City.

The Disadvantages of the Murphy Button. Robert F. Weir, New York City.

Gallstones of the Common Duct. Archibald MacLaren, St. Paul, Minn.

Anatomy of Inguinal Hernia; Andrews' Operation for Radical Cure. D. N. Eisendrath, Chicago.

Four Cases of Strangulated Hernia (Two Femoral, Two Inguinal), Successfully Treated by Primary Resection of Bowel Through Supplementary Abdominal Incision, Followed by Radical Operation at Hernial Site. John Young Brown, St. Louis.

Three Years' Experience with the Autoplastic Suture for Hernia. L. L. McArthur, Chicago.

Old Dislocations; How Shall We Treat Them? De Forest Willard, Philadelphia.

The Treatment of Fracture of the Patella by Lateral Suture. Joseph A. Blake, New York City.

The Treatment of Cold Abscesses and Sinuses in Tuberculous Disease of Bone. V. P. Gibney, New York City.

Impacted Fracture of the Head and Neck of the Femur. Le Moyne Wills, Los Angeles, Cal.

Laminectomy; A Further Contribution. John C. Munro, Boston.

The Surgical Treatment of Certain Cases of Arthritis Deformans. Martin B. Tinker, Clifton Springs, N. Y.

A Successful Removal of Bullet from the Brain. John A. Wyeth, New York City.

Intracranial Neurectomy for Trigeminal Neuralgia; Cases and Comment. Harry M. Sherman, San Francisco.

What Is the Proper Treatment of Suspicious Tumors of the Breast? J. Clark Stewart, Minneapolis.

The Danger of Allowing Warts and Moles to Remain Lest They Become Malignant. W. W. Keen, Philadelphia.

Ten Years' Experience with My Method of Radical Operation for Carcinoma of the Breast. Willy Meyer, New York City.

Kidney Stones; Diagnosis and Treatment. A. D. Bevan, Chicago.

SYMPOSIUM ON THE PROSTATE.

Prostatectomy. James E. Moore, Minneapolis.

Suprapubic Enucleation of the Prostate. H. O. Walker, Detroit.

Prostatectomy, Especially by the Perineal Route. George Goodfellow, San Francisco.

Prostatectomy. Parker Symes, New York City.

Experimental Studies in Gastroenterostomy and Other Reports. H. L. Burrelle, Boston.

Further Report of Four Cases. Charles H. Frazier, Philadelphia.

Excision of the Ulcer-Bearing Area in Gastric Ulcer. W. L. Rodman, Philadelphia.

Fat Embolism of Lung Following Fractures, with Report of Two Cases. F. Gregory Connell, Leadville, Colo.

Matas' Operation for Popliteal Aneurism. J. F. Binnie, Kansas City, Mo.

The Preparatory and Postoperative Treatment of Surgical Cases. L. Sexton, New Orleans.

Surgery of the Trifacial Nerve and Its Ganglia. J. B. Murphy, Chicago.

Beside the above the following will read papers, but their titles have not yet been received: Maurice H. Richardson, Boston: George Ben Johnston, Richmond, Va., and J. H. Burry, Chicago.

Section on Hygiene and Sanitary Science.

Chairman, G. T. Swarts, Providence, R. I. Secretary, J. S. Fulton, 1809 St. Paul Street, Baltimore.

The officers of this section have not favored us with their program.

Section on Ophthalmology.

Chairman, Robert L. Randolph, Baltimore; Secretary, Albert E. Bulson, Jr., Fort Wayne, Ind.

Chairman's Address: Thoughts Suggested by a Study of the Eye Injuries of Independence Day. Robert L. Randolph, Baltimore.

The Treatment of Purulent Ophthalmia. Myles Standish, Boston.

Postoperative Infection of the Eye. J. A. White, Richmond.

Tumors of the Orbit. H. V. Würdemann, Milwaukee; Brown Pusey, Chicago.

A Case of Pulsating Exophthalmus; Successive Ligation of Both Common Carotids; Death. Howard F. Hansell, Philadelphia.

Intermittent Exophthalmus, with the Report of a Case. William C. Posey, Philadelphia.

Diaphoresis and Diaphoretics in Ophthalmic Therapeutics. Hiram Woods, Baltimore, and T. A. Woodruff, Chicago.

The Importance of General Therapeutics in the Management of Ocular Affections. A. Maitland Ramsay, Glasgow, Scotland. (By special invitation.)

(*a*) A Case of Syphilitic Iridochoroiditis of One Eye, with a Marked Perforative Syphiloma in the Upper Ciliary Region; Recovery. (*b*) A Case of Congenital Sensory Alexia, Combined with Paresis of the Superior Rectus of the Left Eye and of the Inferior Rectus of the Right. Herman Knapp, New York City.

Is Bilateral Operation for Cataract Ever Justifiable, and If Not, How Soon After the Operation on the First Eye Is It Safe to Extract the Second Cataract? A. W. Calhoun, Atlanta, Ga.

Reclination of the Lens; Under Certain Conditions a Justifiable Operation. F. T. Rogers, Providence, R. I.

Septic Thrombosis of the Cavernous Sinus, with a Report of Three Cases. E. C. Ellett, Memphis, Tenn.

The Conservative Treatment of Affections of the Lachrymal Apparatus. S. D. Risley, Philadelphia.

The Mathematical Point of Reversal in Skiascopy. Swan M. Burnett, Washington.

Some Injuries of the Eye in Their Medicolegal Aspect. John J. Kyle, Indianapolis.

Blindness and Oculomotor Palsies from Injuries Apparently Not Involving the Optic or Oculomotor Nerves. Alvin A. Hubbell, Buffalo.

The Ocular Symptoms of Lesions of the Optic Chiasm. G. E. de Schweinitz and John T. Carpenter, Philadelphia.

Saccharine Saline Injections in Ophthalmic Practice. L. Webster Fox, Philadelphia.

Operations on the Eyeball in the Presence of an Infected Conjuctival Sac. Charles S. Bull, New York City.

Temporal Cleft of the Nervehead and the Other Fundus Anomalies Often Present with It. Charles H. Beard, Chicago.

Obstructions in the Retinal Arteries. Allen Greenwood, Boston.

Some Problems of Presbyopia. Geo. M. Gould, Philadelphia.

Development of the Faculty of Binocular Vision. Edward Jackson, Denver.

Clinical and Histologic Observations on Sympathetic Ophthalmia. Clarence Veasey, Philadelphia.

Operative Procedures on the Exciting Eye and the Sympathizing Eye in Cases of Sympathetic Ophthalmia. John E. Weeks, New York City.

Sympathetic Ophthalmitis. Samuel Theobald, Baltimore.

The Environment and Visual Requirements of Railway Engineers and Firemen; Personal Observations from an Engine Cab. Nelson M. Black, Milwaukee.

The Molar Teeth and the Patellar Reflex in Interstitial Keratitis Due to Inherited Syphilis. George F. Suker, Chicago.

New Views Regarding the Horopter. George T. Stevens, New York City.

Blastomycosis of the Eyelid, with Report of Cases. William H. Wilder, Chicago.

Brief Report of Additional Cases of Sympathectomy for *Glaucoma.* W. B. Marple, New York City.

An Exact and Secure Tucking Operation for Advancing an Ocular Muscle, Illustrated by Demonstration on a Manikin. F. C. Todd, Minneapolis.

Injuries of the Iris, with Report of a Case of Iridodialysis in Which There Was a Complete Reattachment of the Iris. Ellett O. Sisson, Keokuk, Iowa.

Methyl Alcohol Intoxication. Frank Buller, Montreal, Canada. (By special invitation.)

The Axis of Astigmatism. J. H. Claiborne, Jr., New York City.

The Usefulness of the Ophthalmometer. F. C. Heath, Indianapolis.

The Relation of Corneal Curvatures to the Refraction of the Eye. G. Melville Black, Denver.

Subjective Refraction. John A. Tenney, Boston.

Some New Test Types for the Reading Distance. Charles H. Williams, Boston.

Double Radial Rupture of the Iris Causing a Complete and Well-Formed Iridectomy. S. C. Ayers, Cincinnati.

Section on Diseases of Children.

Chairman, Charles G. Kerley, New York City; Secretary, C. F. Wahrer, Ft. Madison, Iowa.

Chairman's Address: The Demands of the Child by Virtue of Right. Charles Gilmore Kerley, New York City.

Erythema Nodosum in Children. Isaac A. Abt, Chicago.

The Early Diagnosis and Treatment of Whooping Cough. Philip F. Barbour, Louisville, Ky.

Whooping Cough; Its Treatment by Means of the Elastic Belt. Theron W. Kilmer, New York City.

Some Clinical Observations on Malnutrition and Its Relationship to Infantile Tuberculosis. Louis Fischer, New York City.

Amaurotic Family Idiocy: A Report of Two Cases in Sisters. A. C. Cotton, Chicago.

How to Produce the Best Milk for Infant Feeding. Edward F. Brush, Mt. Vernon, N. Y.

The Initial Contamination of Dairy Milk. Richard Cole Newton, Montclair, N. J.

Phlyctenular Ophthalmia. Albert R. Baker, Cleveland, Ohio.

The Effect of Uncorrected Refractive Errors and Muscular Unbalance on the Nervous System of Children. J. H. Claiborne, New York City.

Congenital Occlusion of the Lachrymal Canal and the Acute Inflammation of the Conjunctiva Occurring in Children. John E. Weeks, New York City.

Precautions Used by the New York Health Department to

Prevent the Spread of Contagious Diseases in the City Schools. Thomas Darlington, New York City.

Perinephritis. Wisner R. Townsend, New York City.

Enuresis. Maurice Ostheimer and I. Valentine Levi, Philadelphia.

SYMPOSIUM ON DIARRHEA.

The Bacteriology of Summer Diarrhea. William H. Park, New York City.

A Summer's Experience with Infantile Dysentery. J. H. Mason Knox, Jr., Baltimore.

A Study of 28 Cases of Diarrhea in Children. John C. Cook, Chicago.

The Management of Summer Diarrhea. Thomas S. Southworth, New York City.

Treatment of Acute Diarrhea in Infants, and Its Dietetic Management. Henry L. Coit, Newark, N. J.

Dilatation of the Colon in Children. William Osler, Baltimore.

Hematuria as the Earliest or Only Symptom of Infantile Scurvy. John Lovett Morse, Boston.

Some Points on General Anesthesia in Children. Thomas L. Bennett, New York City.

Diseases of Children Occasioned by Affections of the Nose; the Necessity for Recognition and Treatment. Louis J. Lautenbach, Philadelphia.

The Importance of an Early Aural Examination in Acute Inflammatory Diseases. James F. McKernon, New York City.

The Prognosis of Pneumonia in Infants and Young Children, in Private Practice. L. Emmett Holt, New York City.

Diagnosis of Enlarged Bronchial Lymph Nodes. Alfred Friedlander, Cincinnati.

The Management of Hernia in Infancy and Childhood, with Results of Operative Treatment. William B. Coley, New York City.

Intestinal Obstruction in Children. John F. Erdman, New York City.

Nervous Diseases in Children. Barnard Sachs, New York City.

Chorea. W. C. Hollopeter, Philadelphia.

A Case of Landry's Paralysis in a Child. Henry Enos Tuley, Louisville, Ky.

Lymphoid Affections in the Upper Air Tract of Children. Their Diagnosis and Treatment. Walter F. Chappell, New York City.

Adenoids in Children; Their Treatment, Medical and Surgical. Charles M. Robertson, Chicago.

Chronic Constipation in the Infant. J. Ross Snyder, Birmingham, Ala.

Some Physical Signs in Infants and Children Not Generally Recognized. Samuel McClintock Hamill and Theodore Le Boutillier, Philadelphia.

The Care of Infants in Public Institutions. H. M. McClanahan, Omaha.

A Case Conjoining Myxedema and Diabetes Mellitus. August Adrian Strasser, Arlington, N. J.

Section on Stomatology.

Chairman, G. F. Eames, Boston; Secretary, Eugene S. Talbot, 103 State Street, Chicago.

SYMPOSIUM ON DENTAL EDUCATION.

Chairman's Address: The Value of Symmetry in the Development of Professional Character and Education. George F. Eames, Boston.

The Evolution of Standards in Dental Education. Charles Chittenden, Madison, Wis.

Phases of Dental Education. A. E. Baldwin, Chicago.

Dental Education, a Retrogressive and Prospective View. John S. Marshall, San Francisco.

SYMPOSIUM ON THE DENTAL PULP.

Neoplasm of the Tooth Pulp. Vida A. Latham, Rogers Park, Ill.

Vital Principles in Adult Pulp. R. R. Andrews, Cambridge, Mass.

Degeneration of the Tooth Pulp. Eugene S. Talbot, Chicago.

The Pulp. Jos. Arkovy, Budapest, Hungary.

A System for Surgical Treatment of Hare-lip, Cleft Palate and Facial Deformities and Postoperative Speech Education. George V. I. Brown, Milwaukee, Wis.

Multiple Fracture of Lower Jaw Complicated by Simultaneous Fracture of the Upper Jaw. Thomas L. Gilmer, Chicago.

Impacted Teeth; Their Diagnosis, Liberation and Extraction. Matthew H. Cryer, Philadelphia.

Ankylosis of the Jaw. G. Lenox Curtis, New York City.

Necrosis of the Bones of the Face. Stewart L. McCurdy, Pittsburg, Pa.

Treatment of Pathologic Irregularities of the Teeth. M. H. Fletcher, Cincinnati.

Report of a Case of Vincent's Angina and Stomatitis, with Photographs. George C. Crandall, St. Louis.

Oral Infection and Sterilization. M. L. Rhein, New York City.

Changes in the Salivary Secretions as Affected by Systemic Disease. Heinrich Stern and William Lederer, New York City.

Prophylaxis in Relation to Tooth Environment and to the Prophylactic Value of Materials Employed. Chas. F. Allan, Newburgh, N. Y.

The Physician's Duty to the Child from a Dental Standpoint. Alice Steeves, Boston.

Ethics. Adelbert H. Peck, Chicago.

Section on Nervous and Mental Diseases.

Chairman, F. Savary Pearce, Philadelphia; Secretary, David I. Wolfstein, 22 West Seventh Street, Cincinnati.

Chairman's Address: Nervous and Mental Diseases, Past, Present and Future. F. Savary Pearce, Philadelphia.

Report of Committee on the Collection of Information Regarding Public School Methods and Their Effects on the Mental and Physical Health of School Children. W. J. Herdman, Ann Arbor, Mich.

SYMPOSIUM ON CHOREIFORM AND OTHER SPASMODIC MOVEMENTS.

Symptomatology, Pathology and Treatment of Choreiform Movements. William G. Spiller, Philadelphia.

Convulsive Tic. Hugh T. Patrick, Chicago.

Hysterical Movements. Howell T. Pershing, Denver.

Dementia Precox. F. X. Dercum, Philadelphia.

Early Diagnosis of Paresis. Lambert Ott, Philadelphia.

PHILADELPHIA CLINICS AND DEMONSTRATIONS.

COMPLIMENTARY TO THE MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION FOR THE WEEK PRECEDING AND THE WEEK FOLLOWING THE ATLANTIC CITY SESSION.

The profession of Philadelphia has arranged special clinics, lectures, demonstrations, etc., for members of the American Medical Association attending the Atlantic City Session. These are not to conflict with the Association work but are to precede and to follow. The schedule is given below. Dr. De Forest Willard, 1818 Chestnut Street, chairman of the committee on clinics, writes that the physicians of Philadelphia will be glad to do everything that lies in their power to make the visit of their fellow members of the Association interesting and satisfactory.

Buffet lunch will be served in the dining hall of the University Hospital each day to all members.

Dr. John B. Roberts will entertain the members of the American Medical Association and the members of the American Academy of Medicine at luncheon, at 313 S. 17th Street, Friday, June 3, at 2 p. m.

University of Pennsylvania Clinics and Demonstrations at the University Hospital.

Thirty-sixth and Spruce Streets.

FRIDAY, JUNE 3.

Edsall.—Demonstrations of the Methods Employed in the Analysis of the Gastric Contents. 11 a. m., Medical Amphitheater.
Steele.—Diagnosis and Treatment of Diseases of the Stomach. 12 m., Medical Amphitheater.
Fussell.—Exhibition of Cases of Heart Disease with Special Reference to Myocarditis. 1 p. m., Medical Amphitheater.
Luncheon.—University Hospital. 2 p. m.
Randall.—Stereopticon Demonstration of the Clinical Anatomy of the Tympanic Cavity. 3 p. m., Medical Amphitheater.

SATURDAY, JUNE 4.

Smith, A. J.—Demonstrations of Autopsy Technic and of Pathologic Specimens. 10 a. m. to 12 m., Medical Hall.
Tyson.—Medical Clinic. 12 m., Medical Amphitheater.
Anspach.—Demonstrations of a Series of Natural Color Preparations Illustrating the Value of Routine Histologic Examination of Gynecologic Specimens. 1 p. m., Gynecologic Amphitheater, University Hospital.
Luncheon.—University Hospital. 2 p. m.
Clark.—Gynecologic Clinic. 3 p. m., Gynecologic Amphitheater.

MONDAY, JUNE 6.

Muller.—Pathology of the Pancreas. 10 a. m., University Hospital.
Edsall.—Diagnosis and Treatment of Diseases of Liver. 11 a. m., Medical Amphitheater.
Young.—The Surgery of Paralyses. 12 m., Orthopedic Amphitheater.
Mills.—Some of the Newer Aspects and Methods of Cerebral Localization. 1 p. m., Medical Amphitheater.
Luncheon.—University Hospital. 2 p. m.
Spiller.—Tumors of the Brain. 3 p. m., Surgical Amphitheater.
Frazier.—Surgery of Brain Tumors. 4 p. m., Surgical Amphitheater.

NOTE: Subject of lectures by Drs. Mills, Spiller and Frazier will be Brain Tumors. Each lecturer will discuss or demonstrate a different phase of the subject, so that there will be no repetition.

FRIDAY, JUNE 10.

Opening Exercises of the New Medical Laboratories. 4 p. m.

SATURDAY, JUNE 11.

Allis.—Congenital Dislocation of the Hip. A demonstration on the cadaver, in which both hips will be simultaneously dislocated by a force simulating routine contractions, with brief remarks on the etiology, diagnosis and treatment. 9 to 11 a. m.
Willard.—Treatment of Congenital Dislocation of the Hip. 11 a. m., Orthopedic Amphitheater.

Clinics will close in time for those who so desire to take the 1:20 train for Washington to witness the unveiling of the Rush monument.

MONDAY, JUNE 13.

Evans.—Serum Diagnosis of Typhoid and Other Infectious Fevers. The Precipitins and Their Medicolegal Value. 10 a. m., University Hospital.
Sailer.—Application of the Roentgen Ray in the Diagnosis of Thoracic Diseases. 11 a. m., University Hospital.
Stengel.—Practical Demonstrations of Methods Used in the Diagnosis and Treatment of Valvular Heart Disease and Arteriosclerosis. 12 m., Clinical Amphitheater.
Hirst.—Plastic and Abdominal Surgery for Complications and Consequences of Childbirth. 1 p. m., Maternity Amphitheater.
Luncheon.—University Hospital. 2 p. m.
De Schweinitz.—Ophthalmologic Clinic, with Special References to Ocular Traumatisms. 3 p. m., Gynecologic Amphitheater.
Shumway.—Lantern Demonstration on the Embryology of the Eye. 4 p. m., University Hospital.

TUESDAY, JUNE 14.

Stanton.—Demonstration and Application of the Methods of Determining Blood Pressure. 10 a. m., Medical Amphitheater.
Griffith.—Pediatric Clinic. 11 a. m., Medical Amphitheater.
Musser.—Medical Clinic. 12 m., Surgical Amphitheater.
Martin.—Surgical Clinic. 1 p. m., Surgical Amphitheater.
Luncheon.—University Hospital. 2 p. m.
Piersol.—Demonstrations of Monstrosities. 3 p. m., Medical Hall.
Pancoast.—The Relative Results Obtained with the Roentgen Ray and Radium in the Treatment of Carcinoma and Other Lesions. 4 p. m., Surgical Amphitheater.

Clinics and Demonstrations at the Jefferson Medical College and Hospital.

Tenth and Walnut Streets.

TUESDAY, MAY 31.

Brick, J. Coles.—Rectal Clinic. 9:30 to 10:30 a. m., Hospital Amphitheater.
Roe, W. J.—Oral Clinic. 11 a. m. to 12:30 m., Hospital Amphitheater.
Stewart, Francis T., Surgical Clinic. 2:30 to 4 p. m., Hospital Amphitheater.

WEDNESDAY, JUNE 1.

Jones, W. S.—Laryngologic Clinic. 10 to 11 a. m., Hospital Amphitheater.
Bland, P. Brooke.—Pathology of Certain Pelvic Organs with Lantern Demonstrations. 11 a. m. to 1 p. m., College Building.
Montgomery, E. E.—Gynecologic Clinic. 1 to 3 p. m., Hospital Amphitheater.
Coplin, W. M. L.—Insects and Lower Animals as Carriers of Contagion. 4 p. m., College Lecture Room.

THURSDAY, JUNE 2.

Pathologic and Histologic Laboratories. Demonstrations by Drs. Ellis and Radasch. 9:30 to 11 a. m., College Building.
DaCosta, Jr., J. C.—Recent Advances in Diagnosis by Examination of the Blood. 11 a. m. to 12 m., Hospital Amphitheater.
Cohen, S. S.—Clinical Lecture Illustrating Recent Advances in Medical Diagnosis. 12 to 1 p. m., Hospital Amphitheater.

MONDAY, JUNE 6.

Wilson, H. A., and Professor Hoffa of Berlin.—Orthopedic Clinic. 9:30 a. m. to 12 m., Hospital Amphitheater.
Keen, W. W.—Surgical Clinic. 1 to 3:30 p. m., Hospital Amphitheater.
Fisher, John M.—Gynecologic Clinic. 4 p. m., Hospital Amphitheater.
Hansell, Howard F.—Ophthalmologic Clinic. 4 p. m., Philadelphia Hospital, Thirty-fourth and Spruce Sts.

SATURDAY, JUNE 11.

Fisher, John M., 9 to 10 a. m.; Montgomery, E. E., 10 to 11 a. m.; DaCosta, J. C., 11 a. m. to 12 m., Gynecologic Clinics. Hospital Amphitheater.

MONDAY, JUNE 13.

Pathologic and Histologic Laboratories. Demonstrations by Drs. Ellis and Radasch. 9 to 10 a. m., College Building.
Rugh, J. T.—Treatment of Ankylosed Joints. 10 to 11:30 a. m, Hospital Amphitheater.
Dercum, F. X.—Neurologic Clinic. 12 to 1 p. m., Hospital Amphitheater.
Stelwagon, Henry W.—Dermatologic Clinic. 1 to 2 p. m., College Building.
Metheny, S. A. S.—X-Ray Demonstrations. 3 to 4 p. m., Hospital Amphitheater.
Roe, W. J.—Oral Clinic. 4:30 to 5:30 p. m. Hospital Amphitheater.

Tuesday, June 14.

Brubaker, A. P.—Demonstrations in Physiological Laboratory. 9 to 11 a. m., College Building.
Cohen, S. S.—Medical Clinic. 11 a. m. to 12 m., Hospital Amphitheater.
Brick, J. Coles.—Rectal Clinic. 12 to 1 p. m., Hospital Amphitheater.
Spencer, Geo. W.—Surgical Clinic. 2 to 3 p. m., Hospital Amphitheater.
Stewart, Francis T.—Surgical Clinic. 3 to 4 p. m., Hospital Amphitheater.
Hansell, Howard F.—Demonstrations of the Changes in the Fundus of Eye in Bright's Disease. 4 to 6 p. m., Philadelphia Hospital, Thirty-fourth and Spruce Sts.

Clinics at the Medico-Chirurgical Hospital.

Cherry Street, Seventeenth to Eighteenth Street.

Thursday, June 2.

Mann, James P.—Orthopedic Clinic. 11 a. m. to 12 m.
Christian, H. M.—Genito-Urinary Clinic. 12 m. to 1 p. m.
Gleason, Edward B.—Otologic Clinic. 3 p. m. to 4 p. m.

Friday, June 3.

Rodman, William L.—Surgical Clinic. 10 a. m. to 11 a. m.
Shoemaker, John V.—Dermatologic Clinic 11 a. m. to 12 m.
Anders, James M.—Medical Clinic. 12 m. to 1 p. m.
Mann, James P.—Orthopedic Clinic. 3 p. m. to 4 p. m.

Saturday June 4.

Ashton, W. Easterly.—Gynecologic Clinic. 10 a. m. to 11 a. m.
La Place, Ernest.—Surgical Clinic. 11 a. m. to 12 m.
Boyd, George M.—Obstetric Clinic. 12 m. to 1 p. m.
Rodman, William L.—Surgical Clinic. 3 p. m. to 4 p. m.

Monday, June 6.

Pearce, F. Savary.—Neurologic Clinic. 10 a. m. to 11 a. m.
Haehnlen, W. Frank.—Obstetric Clinic. 11 a. m. to 12 m.
Fox, L. Webster.—Ophthalmologic Clinic. 12 m. to 1 p. m.

Wisconsin State Medical Society, Milwaukee, June 22.

THIRTY-THIRD GERMAN CONGRESS OF SURGERY.

Held at Berlin, April 6-9, 1904.

The President, Professor Braun of Göttingen, in the Chair.

The Pneumatic Cabinet for Operations in the Thorax.

The chief interest at the congress centered in the Sauerbruch air chamber, more fully described in another column, page 1192. The box used as an air chamber had been brought to the congress and its workings were demonstrated. Experiments with over-pressure in the bronchi induced through a tracheotomy opening were well tolerated by animals, but Sauerbruch and Mikulicz doubt whether the human heart would stand the strain of such a procedure. They have established by their research that the principal cause of the danger in case of pneumothorax is not so much the collapse of the lung as the dilatation of the vessels of the collapsed lung. This diverts the blood from the other lung, and, although the latter is functioning normally, as it does not receive sufficient blood, asphyxia is inevitable. Nervous influences also co-operate. The air chamber obviates also some of the difficulties in operating on the esophagus. The cardiac end of the stomach and of the esophagus can be drawn well up into the pleural cavity after detaching them from the diaphragm, and after resection the stump of the esophagus can be implanted in the stomach. The stomach in a dog was drawn up and sutured at this point, and the animal has shown no disturbances during the six weeks since. Another lived four weeks after resection and suture. The sutured esophagus and stomach can be pushed back into their normal place. When this is desired the thoracotomy is best done in the fifth or sixth interspace. The third to the fifth interspace is best adapted for intervention on the upper part of the esophagus. The traction at this point is so great that it is doubtful whether a suture would hold after resection. Mikulicz experimented by tying the ends of each stump and pushing them both out of sight, suturing the wound over them in tiers. The upper stump was then exposed through another incision above and fastened to the skin above the second interspace. The aim sought in this "surgery of the future" is to supply an artificial passageway for the food to pass from the throat into the fistula opening into the stomach, the gap being bridged by some prothesis. The air chamber was applied in the clinic in a case of resection of the esophagus, but the very weak patient succumbed to heart collapse. It was found in this case that the necessary minus atmospheric pressure was 12 mm. The Brauer modification of the air chamber consists in a small box to enclose the head of the subject to be operated on. The anesthetist stands outside and conducts the narcosis with his arms alone in the box, supplying the patient with oxygen plus chloroform. Petersen has still further modified the air chamber by making it double, one for inspiration and one for expiration. He has found that varying the pressure in the lungs exerted a powerful stimulant effect on the heart. He was able to revive animals after complete arrest of the heart. In addition to this, the transient collapse of the lung obtained by suspending the over-pressure for a moment, enables it to be palpated as never before. He applied this new method in resecting a sarcoma of the spine, encroaching on the thorax. The operation was successful, but the over-pressure was not reapplied during the tamponing later, and pneumothorax developed, the patient dying at once. He found that a difference of pressure of only 7 mm. was sufficient to avert collapse of the lungs.

Hepatopexy.

Mayer reported 6 cases of hepatopexy done by Depage of Brussels. He incises below the costal arch and detaches a strip of peritoneum 5 cm. wide, leaving it in contact with the upper lip of the wound. It is folded back on itself and sutured to the posterior aspect of the margin of the liver. All pains from the displaced liver vanish at once and permanently. He thinks that hepatoptosis is frequently overlooked. Franke of Brunswick employs a similar method of hepatopexy, but assures a firmer hold by passing a few sutures directly through the liver tissue.

Ablation of Tumors in Throat.

Gluck of Berlin stated that he now has a record of 9 cases treated by complete ablation of both larynx and pharynx from the base of the tongue to the entrance of the thorax. The esophagus is substituted by a canula, with which the patient is able to swallow without difficulty. The artificial larynx allows intelligible speech. All his 9 patients have been permanently cured to date.

Tendon Transplantation.

Hoffa exhibited a few patients to illustrate the benefits derived from tendon transplantation in his 100 operations. He thinks that a pink tint in the muscle is not indispensable, although desirable. He also mentioned the necessity for maintaining a certain amount of tension in the transplanted tendon. Even if the paralysis is beyond hope of restitution, transplantation of the tendons will enable the subject to discard mechanical support.

Five New Operations on Biliary Passages.

Kehr of Halberstadt has not been able to find in the literature any record of operations similar to five he has performed during the last year. One was a ligature of the hepatic artery for aneurism; one was the direct implantation of the hepatic duct in the duodenum; one was an operation on the common bile duct, which required complete exclusion of the duodenum. Both ends were tied and gastroenterostomy done. In the fourth operation a pancreatic cyst was made to open directly into the gall bladder, and the latter in the stomach, near the pylorus. All these patients recovered. This makes the fourteenth case in which he has made the gall bladder open into the stomach. In the fifth novel operation hepato-cholangio-enterostomy was done. The patient has since died, but no particulars are known after she left the hospital the fifth week in good condition. Enderlen of Marburg remarked that he had never been able to obtain a permanent communication between the intrahepatic biliary passages and the intestine. The temporary opening always healed over later. He, with others, thinks that the common bile duct in Kehr's case probably regained its permeability.

Radiotherapy of Cancer.

A number of communications on this subject were presented, Perthes of Leipsic reporting 29 cases of cancer treated with the Röntgen rays. He denies that they have any action below a depth of 2 or 3 cm. Lassar interrupts treatment as soon as a dermatitis becomes apparent. Jordan of Heidelberg thinks that recurrence of cancer takes the form of the original growth. It appears early when the latter was of rapid growth, while it may not develop for many years in case of a slowly growing neoplasm. In this connection we call attention to a new mode of measuring the force and penetrability of the Röntgen rays, not announced until two days after the congress, by L. Freund of Vienna. It is based on the chemical action of the rays on a colored fluid, a chemically pure 2 per cent. solution of iodin in pure chloroform, prepared and kept away from the light. The sensibility of this fluid to the Röntgen rays is such that a three-minutes' exposure alters the tint considerably, as the rays oxidate the iodin and liberate it. The color changes are much more sensitive than with the chromoradiometers hitherto used, while they afford an exact chemical measure of the power of the rays.

TENNESSEE STATE MEDICAL ASSOCIATION.

Seventy-first Annual Session, held at Chattanooga, April 12 to 14, 1904.

(Concluded from page 1095.)

Membranous Croup and Diphtheria.

Dr. J. T. Herron, Jackson, reported nine cases of membranous croup, in all of which he had used antitoxin with very beneficial results. He believes that if antitoxin were given early and in large doses, there would be very little need for either intubation or tracheotomy.

Dr. J. B. Witherington, Mumford, gave a résumé of cases treated with antitoxin. In all his professional career, he said, he had never used any remedy for any disease that gave him such uniformly satisfactory results as antitoxin in the early stages of diphtheria.

DISCUSSION.

Drs. Frank Trestor Smith, J. A. Crook, William S. Scott, C. P. Fox, J. S. Nowlin and Louis Leroy concurred in the main with the essayists and spoke of having obtained gratifying results from the use of antitoxin.

Chronic Dysentery—A Protest.

Dr. A. B. Cook, Nashville, wished the term "chronic dysentery" to be dropped from the medical vocabulary. He emphasized the following points: 1. Almost without exception the condition so named is purely local. 2. The term chronic dysentery, as ordinarily employed, does not and can not refer to a definite pathologic entity, but rather covers a wide variety of local diseases in no way related to dysentery. 3. A chronic discharge from the bowels, unattended by the well-recognized symptoms of a general systemic disease process, always indicates a lesion of the rectum, sigmoid or colon. 4. The idea of a necessary relation between bloody discharges and chronic dysentery is based on a false assumption and should be both abandoned and forgotten.

Abscess of the Brain.

Dr. W. A. Bryan, Nashville, reported an interesting case, and emphasized the following statements: 1. Cerebral abscess is to be considered chronic after it has been present six weeks. It requires that time for the formation of the so-called pyogenic membrane, which is nothing more than a fibrous limiting wall. 2. A chronic brain abscess may last indefinitely. Cases are reported varying in duration from a few weeks to as much as twenty years. 3. Chronic abscess of the brain may remain confined within the limiting wall indefinitely, causing few or no symptoms, and by extension through the fibrous wall involve the meninges or rupture into a ventricle, producing marked secondary symptoms and early death. 4. Brain abscess frequently follows an otitis media, without evidence of mastoid disease, and might do so, as in his case, even when the cells are completely necrotic. 5. It may result from otitis by direct extension, by large necrotic involvement of the bone, or by thrombophlebitis. 6. Pus from brain abscess is thin, viscid, like synovial fluid, and acid. 7. The most important symptoms, aside from peripheral disturbances, are pain, mental hebetude, subnormal temperature, slow pulse, and vomiting. 8. Increase in temperature above normal signifies either a new involvement of brain tissue or inflammation of the meninges. The latter is usually accompanied by chill. 9. Congestion of the veins of the fundus may be greater on the sound than it is on the diseased side.

Holocain.

Dr. Frank Trestor Smith, Chattanooga, said that holocain solutions may be sterilized by boiling without affecting the drug; it produces no abrasion of the corneal epithelium, and does not interfere with healing of the mucous membrane; it has no effect on the circulation, neither causing anemia, as does cocain, nor hyperemia, as does eucain, and it does not affect the pupil, the accommodation, nor the tension of the eye. He therefore believes it to be the best local anesthetic for general use, and that it should supersede cocain almost entirely.

Conservative Surgery of the Hand.

Dr. Paul F. Eve, Nashville, cited cases which illustrated in a striking manner what can be accomplished by conservative surgery of the hand. In the treatment of the various wounds of the hand, he said every attention should be paid to thorough cleansing and drainage, and no wound should be thought too trivial to receive proper attention. Many a hand has been rendered partially or wholly useless by the improper treatment of injuries.

Present Status of the Etiology of Malignant Growths.

Dr. Raymond Wallace, Chattanooga, stated that inasmuch as the dividing line between various neoplasms is so difficult to determine, and the transition from a non-malignant to a malignant growth depends on such apparently slight causes; that contrary to all infectious conditions which might be considered analogous, there has never been recorded a case of malignancy in the new-born, and exceedingly few cases in childhood, which also militates against any theory of direct heredity; a multiplex and varying etiology seems the most plausible. Intrinsic irritation of the cell proliferating mechanism in the nucleus may, with the advance of cell chemistry, yield certain autogenous factors, but the following may be summarized as extrinsic factors; Various physical, chemical or physiologic irritations and irritations caused by parasitic life, any of which cause an evident disturbance in cell proliferation, which leads to abnormal proliferation and the consequent formation of neoplastic growths. The degree of malignancy depends on the rate and type of proliferation, and the loss of function and consequent reversion of type in the proliferating cells attest the theory of nuclear or chromatin alteration or rearrangement.

Visual Inspection of Railway Employes.

Dr. C. M. Capps, Knoxville, urged that railway companies should realize the importance of having a competent inspector for each railroad division, as a means of more economic management.

The Treatment of Puerperal Infection.

Dr. J. T. Altman, Nashville, urged the importance of more careful prophylaxis. Since the advent of bacteriology, the true cause and pathology of puerperal infection has been settled, and entirely new ideas of treatment advanced, which, he thought, was a decided step forward in the management of the severer types of this disastrous condition. Surgical treatment is not satisfactory.

Venereal Disease and the Social Order.

Dr. O. J. Porter, Columbia, discussed this subject at great length, and concluded that earlier marriages would prove a telling factor among the agencies which tend to lessen the prevalence of venereal diseases.

After-Treatment of Abdominal Section.

Dr. L. E. Burch, Nashville, emphasized the avoidance of opium and the early movement of the bowels in desperate cases in the after-treatment of abdominal sections; also the absence of all relatives and friends from the sick-room until the crisis has passed; the administration of water in almost satisfying quantities from the first; the early propping up in bed, especially in old people; the avoidance of milk as a diet until the sixth day, and last but not least, the use of a saline enema at the completion of every abdominal operation, for the relief of thirst.

Internal Antisepsis in Typhoid Fever.

Dr. J. A. Crook, Jackson, advocated the principle of drainage and antisepsis as the important features in the treatment of typhoid fever, and reported his successful experience in the use of carbonate of guaiacol combined with thymol, menthol and eucalyptol, as internal antiseptics in this malady. While many of the prominent members of the profession had denied the possibility of intestinal antisepsis with any drug or combination of drugs, yet the clinical experience of hundreds who had used intestinal antisepsis proved that the bowel may be rendered practically sterile. Some of these clinical reports the author quoted. In most instances the diagnosis was established by the Widal test and diazo-reaction. Acetozone was mentioned as a valuable remedy in this disease, and testimony given in favor of its use.

Sanitary Advances.

Dr. E. H. Jones, Murfreesboro, said that American sanitary measures and precautions make it possible to inhabit the jungles of our new island possessions, without which the death-dealing enemies to the human organism would devastate our armies, prospectors and speculators. He believes that the much-contended-for army canteen does not add to, but rather depreciates, the resisting forces in combating the prevailing maladies incident to tropical climes.

Tetanus.

Dr. T. J. Happel, Trenton, referred to the exhaustive review of this subject, which was published in The Journal, Aug. 29, 1903, after which he reported three cases in which he obtained good results from the use of calabar bean. He said that Shoemaker calls the calabar bean a curative agent of great value in tetanus, and that under its use in full doses, pressed to its physiologic effects, fully one-half the cases recover.

Other Papers Read.

Dr. W. D. Haggard, Nashville, reported a case of gallstone in the common duct, one of cyst in the kidney, a case of cancer of the umbilicus, a fibromyoma of the uterus, and tubercular ostitis of the femur, and exhibited specimens.

In a symposium on pneumonia Dr. Louis Leroy, Nashville, discussed the bacteriology and pathology; Dr. John A. Witherspoon, Nashville, the early diagnosis and semeiology; Dr. E. G. Wood, Nashville, medicinal treatment; Dr. Thomas L. Maddin, Nashville, general considerations; Dr. J. S. Cain, Nashville, the history and value of blood-letting; Dr. E. A. Cobleigh, Chattanooga, the local treatment, and Dr. C. P. McNab, Knoxville, some causes of error in the diagnosis of pulmonary affections and their explanation.

Papers were also read as follows:

"The Microscope in Diagnosis," by Dr. W. P. King, Lutts; "Inflammation and Ulceration of Sigmoid Flexure," by Dr. F. B. Reagor, Shelbyville; "Duties of the Profession Concerning Fanaticism, Frauds, Fools and Fads," by Dr. Y. L. Abernathy, Chattanooga; "The General Practitioner's Relation to Insanity and Its Management," by Dr. M. Campbell, Knoxville; "Hysteria," by Dr. J. W. McQuillan, Chattanooga; "Therapy of Sodium Chlorid," by Dr. J. S. Nowlin, Shelbyville; "La Grippe and Its Complications," by Dr. A. J. Swaney, Gallatin, and "Leucocytes in Typhoid Fever," by Dr. William Litterer, Nashville.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Dysmenorrhea in Girls.

In cases of dysmenorrhea in girls who have mitral stenosis the *Jour. des Prac.* recommends moderate doses of digitalis and a suppository containing belladonna. The patient should be kept in bed. If there is excessive flow the following combination should be prescribed:

℞.	Ergotin	gr. iss	09
	Quin. sulph.	gr. 2/5	025
	Pulv. digitalis fol.	gr. 1/5	012
	Pulv. cocoæ q. s.		

M. Ft. capsula No. i. Sig.: Two to four capsules daily.

In some cases hydrastis and viburnum prunifolium may be substituted for the ergot combined in the following proportions:

℞.	Tinct. hydrastis		
	Ext. viburni prunifolii flu., āā	ʒii	8

M. Sig.: Ten drops every two hours.

Painting the nasal mucous membrane with cocain has been recommended to relieve the painful menstruation:

℞.	Cocainæ hydrochlor.	gr. x	65
	Aquæ destil. q. s. ad	℥ss	15

M. Sig.: To be applied locally to the nasal mucous membrane until its anesthetic effects are produced.

Acne of the Face.

The following combination containing betulol (which is a methyl-oleo-salicylate comp.) is of service in the treatment of acne of the face:

℞.	Betulol		
	Ung. storacis, āā	gr. xv	1
	Lanolini (anhydrous)	ʒv	20

M. Ft. unguentum. Sig.: Apply with friction every night for ten days, then stop for ten days and recommence the treatment.

Gallstones.

Hirtz, in the *Internat. Med. Annual*, considers it important that patients having a tendency to gallstones should take moderate exercise, and that women should not wear tight corsets. He thinks it of value to confine the patient to a milk diet at times, and to add Vichy water to the milk. When symptoms point to an attack the patient should be put to bed. In order to quiet the patient the author recommends hot baths, lasting from twenty-five minutes to one hour, and the application to the painful region of poultices containing laudanum, or hot compresses, or the following liniment:

℞.	Tinct. opii	ʒvi	24
	Spts. chloroformi	ʒi	4
	Lin. camphoræ	℥v	150

M. Ft. linimentum. Sig.: Apply locally.

At the same time the following combination should be given:

℞.	Antipyrini	gr. xxx	2
	Syr. codeinæ	℥ii	60
	Aq. chloroformi	℥iv	120

M. Sig.: One teaspoonful every half hour or hour while the pain lasts.

In other cases it is advisable to administer anodyne preparations by the bowel. The following rectal injection is of service in such cases:

℞.	Antipyrini	gr. xv	1
	Vini opii	gtt. xv	1
	Aquæ (warm)	℥iv	120

M. Sig.: Thoroughly cleanse the bowel and introduce this solution per rectum. Morphin will have to be given hypodermically in the violent crises. The kidneys at the same time should be carefully watched in order to prevent a deficient urinary flow. Between the attacks hot baths and hot compresses are to be applied to the region of the liver. The bowels are to be moved by rhubarb, cascara, or Carlsbad salts, and intestinal antisepsis maintained by the administration of sodium benzoate or salicylate, or combined as follows:

℞.	Sodii benzoatis	ʒii	8
	Sodii salicylatis	ʒiv	15

M. Ft. cap. No. 30. Sig.: One capsule three times a day. Internally olive oil is worth trying. Glycerin is also recommended, given in ½ to 1 ounce doses (15.-30.) during the period when the colic is most pronounced. Sodium glycocholate is also said to be of service in dissolving gallstones or preventing their formation, given in five-grain (30.) doses three times a day. As to the limits of medicinal treatment Taylor states that operation is not absolutely necessary unless: 1. The patient has suffered from repeated and exhausting attacks from colic.

2. Unless there are signs of suppuration in the biliary passages.

3. Unless there are signs of complete obstruction of the common bile duct. The following suggestions in regard to the time when operation is necessary have been offered by Kehr: In acute cholecystitis, in chronic obstruction of the common

duct, in those forms of colic in which the condition is grave and medicinal treatment unsuccessful, when there is an angiocholitis, or abscess of the liver, in cases of perforation and signs of peritonitis make their appearance.

Hemorrhoids.

The following combinations, serving as a palliative treatment of hemorrhoids, are recommended by *Centralbl. f. Ther.*:

℞.	Pulv. opii	gr. i		06
	Plumbi acetatis			
	Ung. benzoatis, āā	gr. iii		20
	Butyr. cacao	gr. xxii	1	50

M. Ft. suppos. No. x. Sig.: One suppository to be inserted morning and evening; or:

℞.	Spts. chloroformi	gtt. xxx	2
	Vitelli ovi unius		
	Aq. font. q. s. ad	℥iiiss	100

M. Ft. emulsio. Sig.: As an enema; or:

℞.	Bismuthi iodid.	gr. x		65
	Zinci oxidi	gr. viii		50
	Balsami Peruv.	gr. iiss		15
	Ceræ albæ	gr. iii		20
	Butyr. cacao	gr. xxii	1	50

M. Ft. suppos. No. x. Sig.: One suppository to be inserted morning and evening; or:

℞.	Menthol	gr. xv	1
	Cocainæ	gr. xxx	2
	Ext. secal. cornut. flu.		
	Ext. hamamel. virg. flu., āā	℥ss	15

M. Sig.: Apply locally; or:

℞.	Alphæ eucainæ	gr. ss		03
	Morph. muriatis	gr. 1/6		01
	Antipyrini	gr. viiss		50
	Aquæ destil.	ʒv	20	

M. Sig.: As an injection into the rectum; or:

℞.	Ext. secal. cornut.	gr. iii		20
	Morph. muriatis	gr. 1/6		01
	Butyr. cacao	gr. xxii	1	50

M. Ft. suppos. No. x. Sig.: Insert one suppository morning and evening; or:

℞.	Alumin.	gr. lxxv	5
	Liq. plumbi subacet.	gr. xv	1
	Olei olivæ	ʒss	2
	Lanolini	℥iss	45

M. Ft. unguentum. Sig.: To be applied locally night and morning after thoroughly cleansing the affected areas.

Gout.

A. P. Luff in *Ther. Rev.* states that gout is a metabolic autotoxemia, both intestinal and hepatic, which is followed by a deposition of sodium biurate in the joints and tissues.

In the treatment of gout, according to the author, each patient must be studied individually regarding his habits and mode of life. The treatment is divided as follows: 1. The treatment of the paroxysm and the speedy relief of pain.

2. The treatment of the subacute state and the prevention of the recurrence of attacks by promoting the elimination of uric acid and checking its formation through careful attention to diet and hygiene.

3. The treatment of the affected joints with the object of removing uratic deposits and preventing permanent deformity.

He treats the gouty paroxysm by slight elevation of the limb above the body, by warm pack to the joints and by arranging the bed clothing so they do not touch the part. The warm pack consists of cotton wool saturated with the following lotion and the whole covered with oil silk:

℞.	Sod. carb.	℥iv	120
	Linimenti bellad.	℥ii	60
	Tinct. opii	℥iss	45
	Aquæ	℥viii	240

M. Ft. linimentum. Sig.: Apply locally by mixing a small quantity with an equal quantity of hot water. He speaks against leeching, blistering or incisions. Internally the wine of colchicum root is advised, as it reduces the inflammation, relieves the pain and shortens the attack, followed by a mixture of the colchicum with the citrate of potassium, grams 40-60 (2.65-4.00) three times a day. After the attack the colchicum should be left off gradually. Blue mass should be given to move the bowels, followed the next morning by Epsom salts. Chloral, sulphonal, trional or hyoscyamus may be given to produce sleep, but opium should be avoided. Alcohol should be given very sparingly, and only for a weak heart. Meats and beef extracts should be avoided. Between the paroxysms small doses of the resin of guaiac and colchicum are given combined with nux vomica and gentian. For the relief of constipation he advises sulphur or the compound licorice powder with occasional doses of blue mass.

The elimination of uric acid is promoted by the administration of the citrate or bicarbonate of potassium and by the use of as little table salt as possible. The potassium salts are superior to the sodium and lithium salts. Potassium iodid internally tends to lessen the inflammatory thickening of the fibrous structures of the joint, but no medicines will dissolve the sodium urate deposits.

Massage and hot baths are contraindicated in acute gout, but are of value in the chronic form. Meat should not be used more than once a day, but no one class of foods should be entirely excluded without studying the individual case. Intestinal fermentation and putrefaction should be avoided; starchy foods should be used sparingly. The choice of mineral water and mineral springs depends on the purpose for which it is chosen.

Medicolegal.

Visible Marks on Body—Delay in Applying for Autopsy.—The Fourth Appellate Division of the Supreme Court of New York had before it, in the case of Root vs. London Guarantee and Accident Co., a policy of insurance "against bodily injuries sustained wholly and exclusively through external violence occasioned accidentally by visible means," which further provided, "that this insurance does not cover injuries of which there is no visible mark on the body (the body itself in case of death not being deemed such mark)." The death of the insured was attributed by the physicians to angina pectoris, caused by a fall from his bicycle, in which he also fractured his right femur. But the physicians testified that the heart spasms were not attributable to the broken femur, and, as there was no visible mark on the back or chest, the company contended that the anginal pains, even though resulting from the accident, did not bring the case within the compass of the policy. The court, however, thinks this too narrow a construction to put on its language. It says that where it is plain that an accident has occurred, and severe injuries have resulted, and it is a fair deduction from the circumstances that death ensued as the direct consequence of such accident, the policy should be construed to hold the company liable, even though no contusions or marks appear on the body. A man may be killed by a blow over the heart, or by drowning, or by falling from a balloon, and death ensue before reaching the ground, and in each instance there may be no mark on the body, yet death is by accidental means, and should be within the purview of the policy. Furthermore, it says that the insured's pallor and emaciation and decline were apparent after the accident, and furnished visible signs of the injuries. Then, the insured having died on Sunday and been buried on Wednesday, a representative of the company knowing about the death the day after it occurred, the court holds that delay until Thursday, the day after the burial, in applying to have an autopsy performed was unreasonable.

Delaying Calling Physician to Treat Injuries to Eye.—The case of Robertson vs. Texas & Pacific Railway Co. was brought to recover for injuries from a red-hot cinder falling into the plaintiff's eye. There was a special plea of contributory negligence on his part, in not having his injuries properly treated by competent physicians until the injury was rendered more serious than it otherwise would have been. The main charge to the jury, the Court of Civil Appeals of Texas further says, contained the following: "If you should find that the plaintiff was injured by negligence on defendant's part, so as to entitle him to recover, but you should further find that the plaintiff was guilty of negligence in delaying calling a physician and having his injuries treated, and that such negligence on his part aggravated his suffering, and increased his injuries and damages therefrom, you can not, in such case, allow anything for such increase of his injuries or damages, but can allow him for such damages as you find would have been sustained by him for his injuries, had he not been guilty of negligence in failing to obtain medical treatment for himself." Then there was the following special charge given the jury: "The law requires from one who receives an accident or injury to use the same degree of care and caution which a man of ordinary care and caution would use to lessen the effects of the accident, and make as light as practicable the injury. Therefore, you are instructed, if you believe from the evidence that a spark escaped from the engine pulling defendant's train on which plaintiff was riding, and struck him on or about the eye, and if you further believe from the evidence that plaintiff failed to give the same proper medical attention and treatment, and, in so failing, was wanting in ordinary care and prudence, and that the injury, if any, he received, was thus increased, aggravated, or made more difficult to cure, you are instructed that for such increase or aggravation of injury he can recover nothing, but that, if you allow him any damages, it will only be for such injury as would have been inflicted on him, if any, if he had used the same degree of care and prudence to have the same properly treated after the accident that a man of ordinary care and prudence would have used, if you believe from the evidence that he was wanting in such care." Complaint was made of the main charge and that the charges were conflicting and inconsistent. But the court says that the main charge was correct, and fairly submitted the issue of contributory negligence on the part of the plaintiff in failing to use ordinary care to have his injuries treated. It would have been proper to have refused any further instruction on this phase of the case. The special charge, however, did not wholly preclude a recovery by plaintiff, but sought to limit the recovery to "such damages as you find would have been sustained by him for his injuries, had he not been guilty of negligence in failing to obtain medical treatment for himself." The main charge was not so full as the special charge, but they were not inconsistent.

Status of Physician Not Wanted by Patient—Privilege.—The Court of Appeals of New York says, in the case of Meyer vs. Supreme Lodge Knights of Pythias, that the insured was *in extremis*, incapable of acting or deciding for himself, and, from the necessity of the case, any one was authorized to call a physician to treat him. Without his knowledge or consent, a physician was called for that purpose, and for that purpose alone he attended. He found the insured in bed in an upper room of a hotel, "suffering intense pain and vomiting." The insured told him to get out of the room—that he did not want him there—but he did not leave. He remained to treat him as a physician, and, in order to treat him intelligently, tried to find out what the matter was. From information from him, partly in answer to questions, and partly through voluntary disclosures, and from observation of the physical symptoms, he decided that it was a case of arsenical poisoning. Thus informed as to the nature of the disease, he at once administered a remedy, and soon followed it by another. The insured objected, and tried to curse him away from his bedside, but the physician, loyal to the instincts of his profession, refused to listen to the ravings of the would-be suicide, and continued to prescribe in order to relieve suffering and prolong life. The court holds that there was no error in not allowing the physician to disclose on the trial of this case the information acquired under these circumstances. It says that the question was whether there was enough evidence to warrant the trial judge in deciding, as a preliminary question of fact, that such information was acquired "in attending a patient, in a professional capacity," and that it "was necessary to enable him to act in that capacity." The witness was called as a physician, he attended as a physician, he made a diagnosis as a physician, and he administered remedies as a physician. In all that he did he acted in a professional capacity. While it was true that in all he did he acted against the will and in spite of the remonstrance of a man whose condition imperatively called for professional treatment, still the meeting was professional in nature, and all that he said or did was strictly in the line of his profession. Was the subject any less a patient, within the meaning and object of the statute, because he was forced to submit to ministrations designed to save his life? Was the doctor guilty of assault when he gave the hypodermic injection? Was he bound to leave him there to die, without an effort to help him? Was the statute designed to protect those only who are treated by consent, but not those treated through necessity? Does it not mean by a "patient" at least one who is consciously treated by a physician, even without his consent, when the facts tend to show that through bodily suffering his mind had partially lost its hold? Do our humane laws make it the duty of a physician to leave the bedside of a dying man, because he demands it, and, if he remains and relieves him by physical touch, hold him guilty of assault? Either this physician was the physician of the insured, or he committed an assault on him, and was guilty of a crime. If the wife of the insured had called the physician, she would have acted as an agent by implied authority. The bellboy who, in fact, called him, also acted on implied authority, and, when the physician came, the act of the agent in calling him, if subject to revocation in the actual case, would have been in the supposed case. While the physician in either case could have retired, if he remained in either he remained as a physician, the sick man being his patient, and he was acting in a professional capacity when, as a duly licensed physician, he actually treated the insured as a patient. When one who is sick unto death is in fact treated by a physician as a patient, even against his will, he becomes the patient of that physician, by operation of law. The same is true of one who is unconscious and unable to speak for himself. If the insured had been in a comatose state when the physician arrived, the existence of the professional relation could not be questioned. The relation of physician and patient, so far as the statute under consideration is concerned, springs from the fact of professional treatment, independent of the cause which led to such treatment. An examination made in order to prescribe establishes the same relation. So the court is of the opinion that the physician who treated the insured at the hotel occupied the same confidential relation to him as did the physicians at the hospital. The fact that the patient told the physician several times to let him alone, as he wished to die, expressing himself in a brutal and profane manner, did not negative the existence of the relation of physician and patient. The fact of treatment was the decisive test in this case. The statute impresses absolute secrecy on all knowledge acquired by a physician in a sickroom that is necessary to enable him to properly treat the sick person, whether the treatment be with or without his consent.

2 *Appendicitis: Its Relation to Pelvic Inflammation. J. M. Baldy.
3 *Resuscitation After Apparent Death in Chloroform Anesthesia; with a Report of Two Cases. Emil King.
4 *Case of Pemphigus Vulgaris, with Some Observations on Its Bacteriology. A. C. Eustis.
5 Blood Iron. Edward T. Williams.
6 Multiple Myeloma. George F. Zinninger.

1. **Serum Diagnosis.**—Rosenberger attempts to give only the more recent progress in serum diagnosis, and the details of technic are extensively enumerated from 137 communications on the subject in international literature. In summarizing he says that out of 17,280 cases of enteric fever, 16,352 gave positive reactions and 928 did not, leaving 94.6 per cent. positive. In paratyphoid fever 42 cases have been collated and in 40 of these—95.2 per cent.—a positive reaction was obtained. In tuberculosis 221 cases were enumerated, 194 of which, or 87.7 per cent., were positive. Of 390 cases of bacil-

lary dysentery, 318, or 80.2 per cent., gave positive reactions. In the other diseases only a small number have been reported, and hence no reasonable estimate can be given of the percentage of reactions obtainable.

2. **Appendicitis and Pelvic Inflammation.**—Baldy disbelieves in the causal relationship of appendicitis with pelvic inflammation. In his experience the two diseases are rarely associated, and then only as a coincidence. He has not found a single case in which, having found pus in the fallopian tube, he has found pus in the involved vermiform appendix, nor has he found pus in a tube or ovary complicating a perforated or gangrenous appendix.

3. **Chloroform Anesthesia.**—King particularly emphasizes the following points:

1. Deep anesthesia is always a condition of danger. Therefore every precaution must be taken to guard against danger.
2. When serious accident occurs we must have ready a well-matured plan of treatment which meets the indication in the best possible manner.
3. Death usually resulting from failure of the vital centers, the first indication is their stimulation. Artificial respiration, tongue traction and heart compression should be first tried. The application of cold, ether being poured on the abdomen according to Hare, inversion, suspension and succussion, dilation of the sphincter ani and electricity are worthy of trial if the others fail.
4 Hypodermic injections during the stage of collapse are a waste of time. The arterial pressure being *nil* there can be no effect from medication unless the injection be into the heart. They may do good before cardiac arrest or after the contractions are resumed, and then the remedies of value are limited to a few.
5. Injections of ether and alcohol in any form are apt to be harmful. Their effect in overdose is so similar to chloroform in their action on the vital centers that we only add to the danger by their use.
6. Mechanical efforts at resuscitation must not be so rough that internal organs are injured. That this is possible is proved by reported cases where the liver was torn, blood found in the pleura and the tongue wounded.
7. Since we can not know when the molecular changes separating true from seeming death take place our efforts at resuscitation should continue for at least one hour.

4. **Pemphigus Vulgaris.**—Eustis, after reporting a case, gives the results of inoculation and cultural experiments, as well as noticing the previous bacteriologic work in this line. He concludes that in cases of pemphigus a diplococcus can be isolated from the bullas, and when injected intravenously into a rabbit will cause death. A diplococcus removed from the rabbit's blood and identical with that obtained from a case of pemphigus, when injected into a pig, produced a pustular eruption in the latter animal, attended with mild constitutional disturbances. Arsenic is the main remedy to be relied on in the treatment of the disease.

10 *Bilateral Facial Atrophy, with Report of a Case and Its Treatment by the Subcutaneous Injection of Paraffin. Benjamin T. Burley.
11 A Many phased Case of Chorea. Horace E. Marion.
12 A Case of Huntington's Chorea; Its Social Aspects. J. J. Putnam.
13 *A New Treatment of Morphin Addiction. William S. Birge.

7. **Infectious Arthritis.**—By infectious arthritis Goldthwait designates a joint disease resulting from some infectious organism, usually occurring as a sequel of some other disease, with abrupt onset and acute symptoms, being in marked contrast in its progress with atrophic or rheumatoid arthritis. The result of the infection, of course, depends on the more or less dangerous character of the organism. The condition of the blood, lymphatics, urine, etc., are noted. Cases are reported illustrating the different types.

8. **Minor Surgical Lesions.**—In his paper Codman confines himself to minor injuries of the wrist, shoulder and ankle, but remarks that the principles apply to other joints. He says one is astonished to find how often the presence of ecchymosis and accurately localized tenderness are proofs of fracture where no crepitus, deformity or abnormal mobility can be obtained.

9. **Inguinal Hernia.**—The operation here described by O'Conor consists in first, a four-inch incision over the line of the inguinal canal, isolating and opening the sac, separating the adhesions and pushing its contents back into the abdomen. The sac is then drawn downward and, keeping the finger within the sac near the internal ring, he transfixes and ligates the sac with fine silk, then divides it about half an inch below the ligature; the stump recedes into the abdomen and the distal portion is removed. The remainder of the operation is described as follows:

The conjoined tendon and Gimbernat's ligament are next differentiated from surrounding structures, and with left index finger introduced into canal as a guide four "strong" fishing gut sutures are passed from within outwards by means of a full curved hernia needle, about one-third of an inch apart, through the projecting ledge of Gimbernat and external oblique, the ends of sutures are retained outside external oblique and the needle withdrawn.

The free ends are next threaded on a hernia needle with an opposite curve and are carried upward from within outward into substance of and through conjoined tendon. The ends of these sutures are similarly retained outside sheath of tendon and the needle withdrawn.

A straight Reverdin needle, or sinus forceps, is next entered through each suture hole in tendon, passed across just beneath aponeurosis and made to emerge at corresponding suture hole in external oblique, the end of this part of suture is caught in needle or forceps, drawn across and out through suture hole in conjoined tendon, thus both ends of each suture emerge from the same aperture in tendon, and form a most efficient submuscular stitch, excepting the fourth or lowest suture, which is only partially submuscular in that it crosses in front of external ring. These sutures are tied with sufficient force so as to approximate the tendon and Gimbernat, care being taken on adjustment of lower suture so as not to unduly compress the cord. I generally allow enough room for the insertion of my little finger.

The ends of sutures are snipped off and the knots retreat into substance of tendon and each little stitch aperture in sheath of latter is closed by fine catgut suture.

The operation which takes from ten to fifteen minutes to perform is concluded by uniting the skin wound with a continuous blanket suture.

He claims the following advantages: Simplicity, the utilization of the two strongest and most suitable structures for the barrier formation, non-interference with the position and structure of the cord, and freedom from subsequent supervention of orchitis, while there is no splitting up of structures which are never anatomically replaced. He insists on the full use of the left index finger introduced in the inguinal canal during the application of the sutures, protecting the structure of the cord, differentiating the projecting ledge of Gimbernat, and obviating the danger of injuring the external iliac vessels. In his 50 cases no accident occurred. Iodoform gauze dressing is applied, the skin suture removed on the seventh day and the patient allowed out of bed in two weeks.

10. **Facial Atrophy.**—The case reported by Burley was treated by paraffin injections to replace the lost tissue, with marked success, as appears from the illustration and the satisfaction of the patient.

13. **The Morphin Habit.**—Birge's method of treatment is the use of mandragorin, whose employment he had occasion to observe in a private institution in one of the southern states. Five drops of a specially prepared solution are given hypodermically with an eighth of a grain of pilocarpin, and this dose is repeated every two hours. If the symptoms of abstinence manifest themselves the dose may be increased until comfort ensues, even if 15 or sometimes 20 drops of the solution are taken. At the end of forty-eight hours the antidotal and eliminative effect of the remedies is usually complete. A dose of ⅛ or ¼ of a grain of morphin will then produce the same effect as it would before the morphin addiction. That no bad results have ever followed this treatment is shown by the statistics kept of over 1,000 cases in the past three years in the Homestead Sanitarium in Memphis. For heart weakness strychnia nitrate and spartein should be given hypodermically for three or four days afterward, and thorough eliminative measures should precede the dosing.

19 *Ergot in Typhoid Fever. Alfred T. Livingston
20 Laboratory Diagnosis. (Concluded.) M. P. Overholser.
21 *Are the Antidotal Effects of Alcohol, Glycerin, etc., on Carbolic Acid Chemical or Physical? Philip Asher.

14. **Ureteral Catheterism.**—Van Der Poel describes the

method of ureteral catheterism, which he does not consider as dangerous except in cases of bladder infection. As compared with other methods he expresses its advantages as follows:

1. The cystoscope is more easy of introduction than are the separators or segregators, is less painful during the bladder manipulations and much less so during the collection of the urines. Hence, as a rule:

2. With ureteral catheterism we can collect the urines during as long a time as may be thought necessary, the patient not requiring any supervision.

3. A cystoscopic examination of the bladder can be made at the same time, which, in some cases, is useful, in others, indispensable.

4. We are much more certain of the exact results, especially when the two urines are of a similar character, whether clear, bloody or purulent (Albarran); and

5. It is the only method by which we are fairly certain that there is no bladder contamination.

15. *Penetrating* **Wounds of the Abdomen.**—Brown believes in prompt operation in any wound of the abdomen that may be penetrating to its contents. He does not consider the hydrogen gas test of Senn safe. In the majority of cases he advises a median abdominal incision, above or below the umbilicus, personally preferring rather long ones so as to systematically go over the viscera, which he examines in the following manner: The stomach fore and aft, the liver and spleen. Beginning at the angle of Tritz, the small intestine is followed to ileocecal valve; the ascending, transverse and descending colon and the sigmoid flexure are then examined. A thorough examination of this sort precludes the possibility of overlooking injuries to peritoneal contents. Injuries to vessels of the mesentery and omentum can readily be controlled by ligature. Hemorrhage from the liver, pancreas and spleen are harder to manage, but a properly applied gauze tampon should be used. Brown is a great believer in the virtue of irrigation and drainage in the treatment of wounds of this character, using physiologic salt solution in large quantities. He drains with glass, the tube being placed in the pelvis through a stab wound above the pubis, and he thinks it is necessary in all cases where there has been a solution of continuity of the bowel. The patient is placed in an exaggerated Fowler's position. If a gauze tampon is used he invariably endeavors to bring the gauze through the wound of entrance so that the laparotomy wound can be completely closed. Care is insisted on in the closure of the wound. A properly applied over-and-over silkworm-gut suture meets all the indications, though if the patient's condition is good, a buried suture may be used. In resection of the bowel he uses a Murphy button, as nothing else is so quick, and the union, as he has shown, is superior to any known method of suture. A series of cases of wounds of the liver, intestine and pancreas is reported. Of the 9 intestinal wounds, 6 recovered, and of the 3 that died 1 was due to shock and 1 had a general peritonitis, but the third patient, he thinks, ought to have been saved. Of the 5 cases of liver wounds, 4 recovered and 1 died three hours after the operation from shock, the result of hemorrhage. In the pancreatic case the patient recovered. To these he adds 8 cases where laparotomy was performed and no injury to the viscera found, making a total of 23 cases, with 19 recoveries and 4 deaths.

16. **Retrouterine Hematocele.**—Gayler gives the results in Döderlein's clinic in the management of these conditions, having re-examined 36 cases. In 18 a laparotomy had been performed; 1 patient died of sepsis, 15 were absolutely well at the end of four years, and 2 still complained of pain and discomfort. The average time of recovery in the 15 was six weeks. The three who had been operated on by way of the vagina were absolutely well. Conservative treatment consisted in rest in bed, liquid diet and application of warmth to the abdomen. Only 13 of the 15 thus treated responded to the request for re-examination. Eleven were free from their complaints and showed no abnormities on internal examination. He thinks these observations teach that a patient should be given in case of hematocele three weeks of conservative treatment in an institution where surgical interference is always conveniently at hand. Of course, in interrupted extra-uterine pregnancy or violent interrupted pregnancy, operation should be performed at once.

18. **Epilepsy.**—Spratling concludes his paper beginning with a report of cases and finishing with a discussion of the same. He holds that the duration of the disease has much to do with the prognosis. Cases that have been epileptic from early life are less hopeful than those originating later. The mental state also has considerable to do with the prognosis, though in many cases it was found temporarily subverted by excessive bromid medication before admission. The length of time during which patients should be free from attacks before being pronounced cured is variously estimated; he does not see how an inflexible rule can be laid down. The peculiarities of the individual cases must be studied and the period fixed in each.

19. **Ergot in Typhoid.**—Livingston believes that the one element that is the fundamental factor of the fatal conditions is insufficient tone of some area or areas of the vital or unstriped muscular fiber of the muscular coats of the blood vessels, lymphatics and alimentary canal. The sooner this tissue is put on the highest plane of tone the better. He has demonstrated, he thinks, that ergot possesses the function of stimulating, toning and strengthening of whatever unstriped fiber is weak, relaxed, stretched or parályzed, the blood distribution is equalized, and the overworked heart has not to pump against congested peripheral areas. He uses a dram of the solid extract of ergot dissolved in an ounce of sterile distilled (cooled) water, and after filtering the solution, adds two minims of chloroform. Absolute asepsis must be insisted on and the dose to be given hypodermically is ½ to 1 dram from two to six times a day or oftener as indicated in the individual case. He considers this the most important single medicinal agent in the treatment of the disease.

21. **Carbolic Acid Antidotes.**—Asher reports experiments made to determine whether the action of alcohol, glycerin, etc., is chemical or otherwise. He summarizes his results by saying: 1. The physical or chemical properties of the various factors used were never affected, therefore chemical change never occurred. 2. The antidotal power of alcohol and glycerin depends largely on the dilution induced. We know that a drop of sulphuric acid will produce escharotic properties at once while the same quantity in diluted state fails. In addition to that of dilution, alcohol possesses dehydrating and astringent properties, which prevent the absorption of carbolic acid by the tissues.

22. **Gastric Ulcer and Cancer.**—Mayo's article seems to cover in substance the same ground as that reviewed in The Journal of March 12, p. 735, ¶42.

23. **Otitis Media and Pneumonia.**—The complication of otitis with pneumonia is not infrequent, occurring more often than it is recognized, according to Ward. The otitis may exist prior to the pneumonia, and the otitis as a rule is made worse, or an apparently quiescent or healed otitis may be revealed by the pneumonia attack, as the pneumococcus is far more likely to attack a previously damaged spot as the one of least resistance. There may be a simultaneous affection of both ear and lung. In a few cases the ear symptoms are manifested first, as in the one reported by the author. Otitis may be secondary to the pneumonia, and this relation of the ear affection to the systemic condition is the most frequent. The pneumococcus brought up by coughing enters the naso-pharynx, gains access to the eustachian tube, extends by contiguity of tissue to the middle ear and starts up suppuration. This usually occurs when the patient is dull or delirious and may escape the notice of the physician who attributes the symptoms of cerebral irritation and septic infection to the pneumonia. In one of Stacey Wilson's cases the otitis was revealed at the

autopsy, not being previously suspected, and the pathologic changes showed suppurative processes that had evidently existed a much longer time than the pneumonia itself. In the case reported no bacteriologic examination was made, but the author considers that the clinical evidence is in favor of a pneumococcus infection.

24. **Tuberculoma of the Liver.**—Ransohoff reports a case with necropsy and discusses the technic of hepatectomy in such conditions. He thinks that the experimentally demonstrated means of arresting hemorrhage by tying the hepatic veins by transfixion sutures, together with gauze packing, seems an ideal one where applicable.

25. **The Relations Between Ophthalmology, Otology and Dentistry.**—Allport points out the relationships that may exist between oral and dental and ophthalmic and otologic conditions. He does not believe in or is skeptical of the so-called reflex ocular or aural disease of oral origin, where intense purulent or inflammatory conditions exist in the eye and ear. Such, he holds, must be produced either by the migration of infectious micro-organisms or by the extension of the inflammation by periosteal or mucous tissue. He would advise the establishment in all free dispensaries of a dental department where proper oral therapeutics might be administered, and notes with satisfaction a resolution by the National Dental Association in favor of medical colleges having lectureships on oral hygiene, prophylaxis, etc.

26. **Tuberculosis.**—Stubbert finishes his article on the treatment of tuberculosis, and summarizes that with our present knowledge and clinical experience in the treatment of the disease, diet, hygiene, fresh air, etc., are universally accepted as the foundation of all scientific methods, though these alone are insufficient and must be supplemented by symptomatic treatment in the way of antiseptics, tonics and surgical interference when necessary. He thinks that in the next three years we will see a notable advance in immunization and the stimulating effects of light. The physician in the meantime who would prescribe climate alone is as culpable as he who would ignore climate, diet and hygiene for medicinal or other treatment.

27. **Hysteria and Organic Disease.**—Noyes and Newton notice especially the subject of hysteria and the hysterogenic tendency of various disorders. Ultimately, of course, advanced cases of hysteria must develop organic disease. The first physical change may be looked for in metabolism, especially in the urinary secretion. They report cases in which there was albuminuria, granular and hyaline casts in the urine, but the supposition that a nephritis was the underlying cause of the whole train of hysterical symptoms can not be maintained. Another case is reported in which there was apparent kidney involvement, but the patient was fairly scolded out of his disorder. They say it seems reasonable enough to conclude that insignificant trouble in the kidney or anywhere else may, in a neurotic subject, by concentrating his thoughts to that region, produce puzzling hysterical-organic symptoms.

28. **Tuberculosis.**—Perkins recognizes six varieties of pulmonary tuberculosis: 1. A localized fibrous form, which is the most favorable and can stand the most vigorous treatment, with a tendency to fibrous isolation favoring recovery. 2. A fibrocaseous form, when arrest takes place after a considerable portion of lung substance has become affected. With proper care the patient may live years though with a lessened vitality. 3. A fibroid phthisis running a chronic course, found chiefly among persons exposed to the inhalation of irritating dust. 4. Phthisis florida which progresses with only temporary abatement and the patient dies of toxemia without the disease spreading to other organs. Closely connected with this is the fifth type described by Biggs as chronic parenchymatous pulmonary tuberculosis, corresponding with Powell's chronic tuberculous phthisis. They are the cases that are most frequently sent away from home to die. The onset is insidious and there may be little or no cough or expectoration, and, unless late in the disease, the physical signs are not always reliable. A prominent characteristic is the marked general symptoms as compared with the physical signs. While less rapid, it is hardly less fatal than phthisis florida. 6. The acute miliary form, overwhelming the system before the stage of dullness or mucous râles occurs.

29. **Poisoning by the White of Egg.**—Clemens reports the case of a child seized with acute urticaria, edema of the feet and collapse and symptoms of acute gastric irritation, the cause of which was at first unrecognized, but later was found to be the ingestion of food containing the white of egg, custard, ginger-bread, etc. The treatment consisted in cleaning out the gastrointestinal tract with oil, followed by full doses of calomel and later by salol and magnesium sulphate. In each case the attacks were preceded by protracted intestinal indigestion, but all the attacks were without incubation periods and must, therefore, have been intoxications. The family history is negative as regards such idiosyncrasy.

30. **Tuberculosis Hospitals.**—Peterson and Heins describe and illustrate the hospitals that are being built for tuberculous cases at the asylums in Binghamton, Middletown and Ogdensburg, New York.

31. **Urea Deficiency in Gout and Lithemia.**—MacAlester's paper describes the findings in gout and lithemia as regards the elimination of urea and uric acid, determining the former by Doremus' instrument and the latter by Heintz' method. The urinalyses of 20 cases are tabulated, showing a decided deficiency. He considers the cause of this urea deficiency as primarily due to hepatic disorders, and that it is of considerable importance from a diagnostic and prognostic standpoint. In chronic rheumatism the results of urinary analysis do not appear to deviate materially from the normal. His summary is given in the following:

1. Persistent deficient urea-excretion is always present in and characteristic of chronic gouty conditions.
2. The total urea output in gout is considerably lower than that found in chronic Bright's disease, about two-thirds of the amount in other miscellaneous chronic disorders, and only about three-fifths of the quantity excreted in health.
3. Deficient urea-excretion is an important factor in the differential diagnosis between gouty and chronic rheumatic troubles, and between lithemia and certain nervous conditions dependent on other causes.
4. It is not present in chronic rheumatic conditions.
5. It points to perverted hepatic metabolism, and lends color to the Murchison theory of gout, there being in the cases discussed no clinical evidence of kidney trouble in support of the renal theory.
6. A diminished uric-acid excretion is to a certain degree commensurate with that of urea.
7. Gout, goutiness and lithemia are of the same origin, and but modifications of the same disorder.
8. Chronic gouty conditions are in general more amenable to treatment, especially to balneotherapy, than chronic rheumatic affections.

32. **Saddle-Nose.**—Wiener's case was one of congenital saddle-nose in which he dissected away the skin and placed a molded celluloid plate underneath, taking care to avoid undue tension. There was a little swelling for a week or ten days, but the wound healed readily and the ultimate result was better, he says, than that shown in the illustration. He thinks the method is worthy of trial.

41 *Report of a Case of Erythromelalgia with the Postmortem Findings. Arthur S. Hamilton.

source of irritation that has produced them is removed they more or less completely disappear. Tympanites, through increasing intra-abdominal pressure without peristalsis, and even so-called intestinal paralysis are also means to the same conservative end. We should, therefore, be careful about antagonizing these conservative agencies during an acute stage by untimely operation or the giving of food or cathartics. Ordinarily, an interval operation will be needed for the removal of the source of infection and such are almost uniformly successful, attended with a very low mortality. This, of course, does not apply to first-day operations in acute peritoneal infections, the necessity of which is unquestioned.

71. **Formaldehyd in the Urine.**—Kenney reaches the following conclusions from his investigation: Formaldehyd as an artificial ingredient to the urine will lead to deceptive urinalysis, making the urine appear albuminous when it is not, and preventing the typical reaction when albumin is present. Introna's test, namely, the use of formaldehyd in albuminous urine as a reagent, is questioned since the effect of formaldehyd on negative urine is the same, though to a more marked degree than that on albumin in solution, the difference in the color and density of the precipitate being immaterial in Kenney's opinion. The therapeutic use of urotropin is a matter worthy of study from the point of view of possible production of pseudo-albuminuria.

72. **Divulsion of the Sphincter for Constipation.**—Tuxbury holds that in certain cases of constipation the constant irritation of the retained feces causes a hyperintensified action of the external sphincter which is beyond the power of the will to control. In such cases gradual divulsion of the sphincter is advisable, and he reports a case to demonstrate its efficacy.

73. **Osteomyelitis of the Skull After Otitis.**—Richardson reports and discusses a case in which there was an osteomyelitic condition involving the temporal bone. It was treated by exposure and curetting with success. He holds that this disorder is probably more common than has been reported to date, the operator not appreciating the character of the invasion, and that cases have been lost because they were considered only a severe type of mastoiditis running an atypical course. In his case he anticipates the objection to the term osteomyelitis by saying that there was no question but what it was clinically and anatomically different from typical mastoiditis, extending far beyond the confines of the mastoid and attended with profound general sepsis from the onset. As it extended rapidly and was not limited by sutural borders, and corresponded to all the symptoms of acute primary osteomyelitis, no other name would be correct.

74. **The Acid-fast Bacilli in Otitis.**—De Simoni reports a case where a bacillus morphologically resembling to some extent the tubercle bacillus, was found abundantly in a case of otitis. It was straight or only slightly curved; the bacillus looked longer and more slender than the common tubercle bacillus, particularly in liquid media and recent cultures. It stained with the ordinary aniline dyes quite like tubercle bacilli, and was not decolorized by Gram. It was non-pathogenic to guinea-pigs and rabbits.

81 *Relative Prevalence of Contagious Diseases in Children of School Age. P. H. Bryce.
82 *Study of Immunity in Variola and Vaccinia. C. A. Hodgetts.

79. **Antitoxic Sera in Tuberculosis.**—An experimental study of antitoxic sera in tuberculosis is reported by Nicholls. He used goats for producing his serum, experimenting on rabbits and guinea-pigs. From the autopsy findings in at least one of his experiments and in the effect on rabbits it would seem that the treatment had some restraining influence on tuberculous processes, not powerful enough, however, to overcome it. He thinks that in view of all the facts known, it must be admitted that it is possible to prepare a serum that is to a certain extent antitoxic toward tuberculosis, but the evidence that the serum so far prepared is curative is very unconvincing to him. Serum may be antitoxic only or it may be germicidal, and in tuberculosis we need both qualities. Short of killing the germs *in situ* he does not think we will achieve success.

81. **Diseases of School Children.**—Bryce discusses the incidence of disease in school children, especially scarlet fever and diphtheria. He says the more effective methods adopted in Ottawa in 1903 have caused a reduction of 50 per cent. in the cases of scarlatina and of 85 per cent. of deaths; 41 per cent. in diphtheria with 54 per cent. of deaths. He thinks there should be a general conviction that disease is liable to be disseminated among school children and that an enormous saving of sickness and mortality is possible if the public is properly educated to action in the matter.

82. **Smallpox.**—Hodgetts holds that the immunity to smallpox after vaccination and more especially after mild attacks of variola is only relative and that there is a danger of serious consequences if those who have suffered from a mild epidemic, such as lately existed, should be left without further protection. We calculate the immunity ordinarily from some former experiènce when the disease may have been of a much severer type.

83 *The Necessity of a Knowledge Among General Practitioners of the Diagnosis and Treatment of Glaucoma. D. B. St. John Roosa.
84 Complications of Chronic Suppuration of the Middle Ear—Etiology and Diagnosis. T. Passmore Berens.

83. **Glaucoma.**—Roosa points out the advantages of an acquaintance with this condition on the part of the general practitioner, especially in treating eye diseases, to avoid mistakes. An error in diagnosis may lead to a complete loss of sight and a remaining eyeball which is a constant source of discomfort and pain, and sooner or later both eyeballs may be affected. The practitioner should learn to recognize intense, neuralgic pain, circumcorneal redness, anesthesia of the cornea, great failure in vision, general turbid look of the front of the eye, and, above all, the hardness of the eyeball as compared with the normal eyeball. In some cases the diagnosis must be reversed on account of the possibility of intraocular tumor, but aside from the increased tension the pupil will show a reflex or there will be a lateral enlargement of the globe. He prefers eserin as the treatment for these cases, using castor oil as a vehicle. If afterward fomentations are used for not less than twenty minutes, the pain is much relieved. The strength of the eserin may be up to 2 grains to the ounce, or even more. Illustrative cases are reported.

88 **Necessity for Supplementary* Measures After the Removal of Adenoids. Percy Fridenberg.

86. **Rachitis.**—Freeman, from his study of the subject and the literature, concludes that from animal experiments it would seem to be indicated that unsuitable food can produce rachitis, and that possibly certain bacteria or intestinal toxins may have the same result. The clinical observations are too elaborate for possible deduction, but are interesting inasmuch as they show less rachitis in tenement than in institution children fed on modified milk, and the greatest amount of rachitis in institution babies fed on breast milk with auxiliary feedings of condensed milk.

87. **Incubation Period of Acute Exanthemata.**—The incubation period of scarlatina, measles and rötheln are discussed by Hand, who finds a wide difference of opinion in all cases excepting in measles. He reports the history of a family epidemic in which the incubation period of scarlet fever must have been thirteen to seventeen days, or much longer than is usually credited. He thinks much harm might have been done if the disease had not been sufficiently severe to have been positively recognized and had been called rötheln. In regard to measles, the incubation period may often be of value in small family epidemics, helping to tell when other members will develop the disease. Beyond this it has little value.

88. **Adenoids.**—One aspect of the study of adenoids has, Fridenberg says, received too little attention from the profession, namely, the after-treatment and the need of supplementary measures for assuring the operative results, producing the habit of nasal respiration and correcting structural deformities due to abnormal functioning. The removal of adenoids does away with the obstruction, but does not insure nasal respiration, and training of the child is required. After the nasal respiration during waking hours has been established there will be no mouth breathing during sleep, and he suggests indulgence in the habit of chewing gum for a period to assist in the reflex mechanism of keeping the mouth shut. It is not difficult to break the habit after its utility is past. He mentions a mechanical splint for keeping the mouth shut during sleep, thus aiding the treatment. The second detail to which the after-treatment should be directed is the faulty arrangement and crowding of the teeth, the malformation of the alveolar arch and the underdevelopment of the jaw and chin. Removal of adenoids in itself will not cure this, and he believes in the intelligent dental surgeon's intervention in such cases.

93 *What Is to Become of the Medical Graduate? John L. Irwin.
94 *The Use of Large Probes in the Treatment of Stricture of the Nasal Duct. R. W. Gillman.

93. **What Is to Become of the Medical Graduate?**—Irwin uses the state board of health figures to show the decrease in the prevalence of disease and of general morbidity and mortality. He figures a total falling off in sickness of 19 per cent., and from this deduces that the income of doctors is necessarily decreasing. Moreover, certain diseases, such as smallpox and scarlet fever, are cared for in most communities by public appropriation. The other disorders on which the general practitioner depends for the bulk of his practice have fallen during the past two years 47 per cent. below the average of the preceding ten years. The number of Michigan physicians is put down as 4,400, and there is an annual increase from the output of graduates from six medical colleges in the state and from incomers from outside the state. He says: "Bearing in mind the altruistic effect of the sanitarian who reduces the percentage of disease, and the egotistic effort of the medical college professor who lures the unsuspecting freshman to swell the ranks of the noble profession of medicine, and the confiding optimism of the said freshman who, after graduation, sits back and waits for the problematic increase in a sick rate which the sanitarian is paid to reduce, and from which his former professor expects to derive sole benefit, the question is: 'What is to become of the medical graduate?' "

94. **Stricture of the Nasal Duct.**—Gillman recommends the use of large probes after slitting the upper or lower canaliculus. He then uses a No. 5 probe and rarely fails to make the passage direct. At the second séance a No. 7 or even a No. 8 probe may usually be readily passed, gradually increasing until a No. 14 or 16 is reached, when the interval of time between the probings is gradually increased to three or four days, a week or two weeks, a month and even longer periods. The probes are allowed to remain *in situ* from ten minutes to half an hour at each sitting. Since adopting the larger probes he has discarded the routine syringing of the sac in cases of dacryocystitis, but orders a collyrium composed of boric acid and zinc sulphate dropped into the affected eye twice daily. Any internal disease of the nose must, of course, be treated. He thinks if this course were followed many operations such as extirpation of the lachrymal sac or gland would be avoided.

95. **Uncinariasis in Porto Rico.**—Ashford and King's article gives a very full account of the conditions in Porto Rico and the methods of treatment which were adopted there. The practice advised is the giving of a full dose of Epsom salts, following it with 4 grams of thymol, avoiding any solvent of this drug. The bowels having moved well, he keeps the patient in bed, and at 7 a. m., withholding breakfast, administers 2 grams of thymol powder, in 6 cachets. He repeats the dose at 8 a. m., and at 11 or 12 gives another dose of Epsom salts, which is a physiologic antidote and effectually stops absorption. The thymol benumbs or kills the parasites and the Epsom salts carry them off. He finds for the after-treatment that Blaud's pills are as good as any preparation. The complications are treated as they arise. The prophylaxis of the condition is dependent on the sanitary arrangement. The use of latrines would be a great help, and he thinks plowing the ground at fortnightly intervals would kill off a great many of the parasites. Cutting down the underbrush and firing the grass would be a good thing. The treatment of as many cases as possible will reduce the danger.

11 Traumatic Rupture of the Small Intestine. R. Lawford Knaggs.
12 Note on Perineal Litholapaxy (Keith's Modification). A. Hooton.

2. **Decapsulation of the Kidney.**—Hall and Herxheimer's experiments were performed on rabbits and dogs. Experiments on healthy dogs were also communicated to them by Harold Johnson. They describe the methods and remark that while they can not produce an interstitial nephritis and reproduce the actual condition observed in the human subject, there is no good anatomic basis for the operation in degenerative nephritis. If the changes are at all analogous in the human subject, they should imagine that the laceration, hemorrhage and the new formation of the capsule would rather tend to accelerate the interstitial inflammation; while in the event even of any concomitant arteriosclerosis there would be no possibility of much vascular anastomosis of replacement of the channels ruptured. But if there is no anatomic basis for the operation there may be another explanation of the rapid flow of urine—the increased excretion of urea and the disappearance of albumin in cases which have been observed to follow decapsulation. By some, the effects are attributed to relief of the congestion, but in their experiments intense hyperemia persisted after the capsule had re-formed. The explanation suggested by Pel, Jaboulay and others that the improvement is due to the action of the sympathetic ganglion raises the question as to the necessity for the entire denudation of the renal capsule. The authors ask if renal puncture or one longitudinal and several transverse incisions would not be a better method. They can not give any experimental evidence on this point, and refer to favorable statistics of Guiteras, Suker and others, but say that they are minimized by several considerations: 1, the limitation of the operation to the later stages of the disease; 2, the exact stages and extent of chronic nephritis do not permit of accurate diagnosis; 3, chronic nephritis is characterized by acute exacerbations and frequent remissions, though its anatomic course is generally progressive. Their general opinion as reflected in their comments is not exactly favorable to the operation. They call attention to the fact that such operators as Israel, Nicolayson and others have abandoned the method. It is, of course, a matter of common knowledge that the simpler renal puncture relieves tension and promotes renal function, so perhaps the description of the changes observed after decapsulation may emphasize the probability of rapid local reparation when temporary obstruction is removed, and this suggests earlier surgical treatment of postfebrile and acute renal manifestations which, when unrelieved, are often fatal.

4. **Digestion and Absorption of Hemoglobin.**—The conclusions reached by Halliburton as to the absorption of hemoglobin are in substance as follows: 1. The administration of iron in the form of powdered hemoglobin to rats causes an increase in the number of their red blood corpuscles and the amount of hemoglobin in the blood. 2. There is every reason to believe that hemoglobin is actually absorbed. The intensity of the ammonium sulphid reaction is much greater than in animals kept on an iron poor diet. The main situation for absorption, as judged by this reaction, is the extreme pyloric end of the

stomach and the first few inches of the duodenum. The spleen appears to be the principal organ for storage. 3. Hemoglobin in the stomach is converted into acid hematin. This constitutes the "coffee grounds" in the vomit of hematemesis. Acid hematin after it is formed, is slowly precipitated, and is indiffusible through parchment paper. This will account for the absorption in the first part of the duodenum. Lower down where the reaction is again acid, the absorption ceases. In many animals, however, the reaction of the intestinal contents becomes alkaline owing to the ammonia formation in the large bowel, but in the rat he found that the contents of the cecum and of the first part of the colon were still acid. Alkalinity does not occur until the lower portion of the colon is reached.

5. **Cancer Mortality in the Thames Valley.**—The statistics of all the counties showed a cancer death rate higher than that of England as a whole. There is an increase in the later decennia over the former of between 1 and 2 per cent., and, as a rule, a larger increase in the riparial districts than in the non-riparial. The figures are compared with the total number of deaths from all causes by a method which can give only approximately accurate results. The conditions in regard to age and sex distribution in the main districts vary but slowly, and there is little liability to error in comparing the cancer death rates of the same district or town at the different periods. The statistics seem to justify the conclusion that the Thames Valley has a relatively high mortality from cancer and the uniformly high rate on both of the banks suggests that there may be a connection between the river floods and the extent of the disease, but it is not explained. If we presume a parasitic origin of the disease, the drying vegetation on the river banks may be a favorable nidus for the growth of the parasite. The facts seem rather to support this view, but it does not explain the cause of the increase of cancer which is everywhere apparent. Given, however, other unknown predisposing factors, lowered vitality and impaired resistance, we may have along the banks of the river a more or less constant manufactory of the materies morbi.

6. **The Action of the Blood Serum of Acute Insanity on Bacillus Coli.**—Johnson and Goodall publish a table showing the agglutinative power of the serum of 100 cases of acute insanity on mixed and single strains of the colon bacillus, also the results in 29 cases of acute melancholia and 53 cases of acute mania. From these tables the following conclusions are drawn:

> 1. In 50 per cent. of the total cases of acute insanity there was agglutination, whereas this was present in only 15.5 per cent. of the controls. 2. The agglutination was partial in the great majority of the cases (39 per cent.). 3. In those forms of the disease in which the cases were sufficiently numerous to permit of percentages being taken (mania and melancholia) the preponderance of partial over good agglutination was also obvious. 4. The percentage of agglutination (good and partial) was greater (58.5) in the cases of melancholia than in those of mania (45.2). 5. The percentage of good agglutination was greater in melancholia than in mania. 6. Even when the disease is quite recent in duration there is as often as not a failure to agglutinate.

21 A Non-toxic Preparation of Iodin. V. H. Wyatt Wingrave.

13. **Skull Fractures.**—Rawling's elaborate lecture discusses the mechanism of skull fractures, especially of the base, showing the greater resistance of the vault and the theories on which the basal portions are likely to participate in the lesion. He thinks that the bursting and compression and "contrecoup" theories of basal fractures are both untenable and that Aran's irradiation theory with certain modifications accounts satisfactorily for those basal fractures that follow blows on the vertex. Most basic fractures, he thinks, result from force applied directly around the basic level, and are the result of a splitting force, the line of fracture tending to travel across the base, parallel to the original direction, though not necessarily in the same straight line. The influences of sutures, of the basic foramina, of air sinuses and of the arrangement in the auditory region are also discussed. Fractures of the vault may be limited or may coexist with basic fracture and the greater the force the greater the tendency to limitation, while force applied obliquely downward usually results in extension toward the basic area. The possibility of fracture of the external table without injury to the internal table was until recently disputed, but the late war in South Africa has demonstrated the existence of such a fracture. Fractures of the internal table are most common where the diploic tissue is most abundant, and that is the mid-parietal and anterior frontal regions, where they may occur without any apparent injury whatever to the external table, but where the external table is fractured there is very probably also a fracture of the internal one, producing many complications. The prognosis in fractures of the anterior fossa are most favorable. Fractures of the middle fossa are most dangerous from local complications, infection from the nasopharynx, ear and injury to the arteries, but the mortality is probably progressive from before backward in these fractures and the proximity of the vital centers in the fourth ventricle renders posterior fossa fracture especially dangerous. The general mortality of all fractures with or without depression is from 20 to 25 per cent.; least in children, highest in old age. The possibility of recovery in posterior fossal fracture is admitted by most, though some deny it. He closes with some remarks on the medicolegal aspect of skull fractures.

14. **Marmorek's Antituberculous Serum.**—Latham has employed Marmorek's serum obtained from Marmorek himself, and thinks that when given in carefully graduated doses with proper precautions and in suitable cases it does no harm. Moreover, his experience tends to show that it does produce a specific antitoxic effect. An extended trial, he thinks, should be made, but it must not be forgotten that great care must be exercised in the administration, and it should be continued for a considerable period before definite results can be expected. He at first injected it under the skin in doses of 10 c.c. every day for a number of days, following this by an intermission and giving it again in reduced dose. Now he uses a dose of 5 c.c. for four consecutive days followed by three days of rest, having two or three repetitions of this, but after the third series giving at least two weeks' intermission. He thinks he has seen patients improve during periods of intermission.

15. **Epilepsy.**—The summary of Turner's article is given as follows:

> 1. A total of 161 cases, which have been under my observation at the Colony for Epileptics, Chalfont St. Peter, has been used for the investigation. 2. The mental features of the interparoxysmal state have been divided for descriptive purposes into four classes, the first containing those epileptics without any obvious mental impairment and the fourth those with the highest grade of dementia. 3. The interparoxysmal mental condition is discussed in its several varieties and degrees, with special reference to the influence of sex, hereditary disposition, age at onset and character, duration and frequency of fits. 4. Sex has little influence on the mental condition, but it may be stated in general terms that males are numerically more afflicted than females (91 per cent. of the former to 78 per cent. of the latter), but that the highest degree of dementia is somewhat more common in women than in men. 5. A family predisposition to epilepsy and insanity, although not necessarily militating against the retention of normal mental faculties, favors the supervention of some degree of mental impairment. A higher percentage with a hereditary history is found among those epileptics who show the profounder degrees of dementia, than among those who show merely impairment of memory, or a normal mental condition. 6. The duration of the disease influences to some extent the mental condition. Mental impairment is less frequent when the fits have lasted for under five years, just as mental integrity is less commonly seen when attacks have persisted for ten or more years. But mental health and mental deficiency are observed in cases in which the disease has lasted respectively for over twenty years and for less than five years. 7. The age at the onset of the convulsion influences to some extent the subsequent mental condition, for the earlier the onset, especially during infancy and childhood, the less the probability of an unimpaired mental state. 8. The character and combination of the fits have an important relation to the mental condition, the profoundest degrees of dementia being most commonly seen when the major and minor attacks coexist. The petit mal seizures occurring alone are found with the lower grades of mental impairment. When the grand mal occurs alone mental health is as common as mental deficiency. 9. There is a direct association between the frequency

of the fits and the mental state—the more frequent the seizures the greater the degree of mental impairment, and vice versa. Fits recurring in series are accompanied by a high grade of dementia. 10. The term "facies epileptica" is applied to the physiognomy characteristic of the disease in many epileptics. It is found more commonly with the higher grades of dementia, but its existence is not limited to such cases, for it is observed in those with only impairment of memory as well as without any mental failure. 11. The view is upheld that the interparoxysmal mental condition seen in most cases of epilepsy is one expression of the neurosis of which the fits constitute another; that the former is therefore not directly dependent on the seizures, and that the frequency and charactercombination of the paroxysms in association with the degree of mental failure indicate the severity and intensity of the disease. 12. The following figures show the percentage frequency of the four classes of mental deficiency among the 161 cases used for the purposes of this paper: Class A, intellectually normal, 13.6 per cent.; Class B, with impaired memory, 31.6 per cent.; Class C, feeble minded, 25.4 per cent.. and Class D, demented, 29.1 per cent.

His paper is an elaborate statistical study covering all the points mentioned above.

16. **Cardiac Dullness in Cancer.**—Gordon observed in the routine examination of several patients with gastric cancer that though no evidence of ordinary emphysema existed, the area of cardiac dullness was very much reduced, if not actually obliterated. The reduction or obliteration of cardiac dullness was sometimes associated with a rather surprisingly small and soft pulse. He has become so sure that this suggests cancer that he has risked a diagnosis on it, and in five consecutive cases the diagnosis proved correct. Putting aside cases where special causes exist, either for the obliteration of the heart dullness or for the prevention of such obliteration, the following, he says, seems to be true:

1. Great reduction or obliteration of the normal cardiac dullness is common in cases of cancer, particularly in cancers of the alimentary canal and in their late stages. 2. This loss of cardiac dullness does not seem to be found in the earliest stages of a cancerous case. but may precede cachexia, marked wasting and loss of skin elasticity. 3. It is rarely observed in non-cancerous cases. 4. It is rarely absent in the later stages of cases of cancer of the alimentary canal. 5. It does not seem to occur in cases of sarcoma. 6. In doubtful cases its presence is highly suggestive of cancer; its absence is slightly suggestive of the absence of cancer. if the symptoms under consideration have lasted for several months.

A number of cases are reported.

19. **Dilatation of the Heart.**—The theory of development of heart dilatation held by Colbeck is that of impairment of its muscle power. He thinks the same theory might explain the mode of production of dilatation of other hollow muscular viscera, stomach, intestines, etc.

31. **Pigmented Syphilids on the Neck.**—Hulleu concludes from a study of 23 subjects out of a much larger experience that roseola occurs on the neck much more frequently than is generally supposed, but it is usually so fleeting that it escapes observation unless special watch is kept for it. The spot occupied by the roseola is the site of the syphilid later. The pigmented ring around it is probably the result of the disturbances in the circulation immediately surrounding the cicatricial relics of the roseola.

32. **Surgery of Hypertrophic Acne of Nose.**—Dubreuilh now operates on a nose showing signs of hypertrophic acne, without waiting for the organ to assume great size. He relates the particulars of 6 pronounced cases, the illustrations showing the entire relief of the deformity. He makes an incision on the median line and then dissects out the tumors on each side, the finger in the nostril as a guide. There is very little hemorrhage. He prefers to cut off slices after the first large mass has been removed, applying thermocautery at once to each raw surface, and thus carving out a good shaped nose, leaving always the inner wall .5 cm. in thickness at least, a little thicker at the nostrils and a little thinner at the tip of the nose. A groove should also be made with the thermocautery to define the ala nasi, where cicatricial retraction is liable to be excessive. As asepsis is out of the question, he dresses the raw surfaces with boricated dressings; the eschar drops off in six or seven days, at which time there is liable to be a little secondary hemorrhage, always easily controlled. By the end of the second week most of the wound has healed, that is, wherever sebaceous glands existed; those parts alone where the surface was purely fibrous take longer to heal. This is the time to apply the Thiersch flaps. He takes them from the arm and covers the surface well with them. The flaps must not be too thin. The results of this decortication and transplantation have been definite in all his cases. No recurrence has ever been reported, and in one of the cases described the acne on the cheeks subsided spontaneously after the healing of the nose. Even superficial decortication seems to arrest the progress of the affection, which suggests that the subepidermic layer is the seat of the trouble, and also that any deformity of this kind may be arrested in its early stages.

33. **Treatment of Leprosy.**—Brault advocates mercurial treatment of lepers for the reason that marked improvement has followed its use in many cases; it is also convenient, as the personnel of the dermatologic clinics are trained in mercurial treatment, and also because it places the lepers on the same plane as the other frequenters of the clinic and leaves them a ray of hope, the physician thus dissimulating his conviction of the powerlessness of medical aid in this inevitably fatal disease. Let us relieve and console, Brault continues, since we can not cure. Hygiene and local treatment, with minor surgical interventions as needed, will relieve and prolong life in these cases. In his experience numberless remedies and local applications were tried, none more than transiently beneficial.

35. **Pyemic Cutaneous Affections.**—Lebet draws the clinical and histological picture of the pyo-septicemic dermatoses caused by microbes brought to the skin by the blood. He calls them pyemic or metastatic dermatoses and points out the points of resemblance between those caused by streptococci and staphylococci and the syphilitic and typhoid roseola, the macula of lepra, etc. These pyemic skin affections may be purpuric, pustulous, varioliform or nodular in character. There is no reason for classing them as angioneuroses; they are not erythemata, but inflammations.

43. **Diagnostic Sign of Epithelioma in Hairy Regions.**—Audry calls attention to the persistence of apparently normal hairs in a chronic ulcerated patch, as a sign of epithelioma. Solidly implanted hairs in or between the masses of the growth occur only in this kind of a chronic ulceration.

44. **New Form of Dermatosis Induced by Pilocarpin.**—A man of 52, previously healthy, consulted a distinguished ophthalmologist last December on account of an ocular affection diagnosed as episcleritis with exaggerated tension, an attack of

subacute glaucoma. He was treated by instillations of a .5 per cent. solution of pilocarpin and hypodermic injections of the same, at first .5 cg. and then 1 cg., with 3 gm. of sodium salicylate daily. After fifteen days of this treatment vision had improved and the dose of pilocarpin was reduced to .5 cg., but twelve days later exacerbation of the eye troubles having been noticed, the dose was increased again to 1 cg. On suspension of this treatment after it had been continued for thirty-five days, a peculiar dermatosis developed with symptoms indicating intoxication, the disturbances affecting the nervous system, brain, circulation and miction, with death the sixty-third day after commencing treatment. The papulo-exudative dermatosis was localized in the sweat glands, affecting mostly the face and members. The exudate was at first limpid, but soon became purulent. The papules in the plantar region persisted without opening. The clinical characteristics of this dermatosis differ from every other known to date. The severe disturbances in the brain and heart innervation are especially striking features, as also the absence of fever, and the lack of any antidote for pilocarpin and of means to insure its elimination. Hallopeau formulates the law that every morbific agent exerts an action specific to itself on certain elements of the organism into which it is introduced, while, on the other hand, each of these elements opposes a specific resistance to it.

46. Tuberculous Inmates of Paris Hospitals.—The isolation of tuberculous subjects is the question of the day at Paris, as has been mentioned in our news columns of late. The *Presse Médicale* has been collecting the exact number at present sheltered in the hospitals and finds that in the 106 different medical and surgical "services" there were 8,836 patients under treatment on March 17, 1904. Of this total number 1,789 were tuberculous, including 1,172 men, 536 women and 81 children. The "closed" cases numbered 540, of whom 292 were men, 206 women and 52 children. The "open" dangerous cases numbered 1,249, of whom 880 were men, 330 women and 39 children. This is a proportion of about 22.5 per cent. of the total number of the hospitalized. The capacity of the Paris hospitals is estimated at 7,194, and their crowded condition is shown by the large number over this figure now sheltered in them. The city of Paris has appropriated $9,000,000 for the reconstruction of its hospital service, and is anxious to eliminate the chronic cases to make room for the acute cases and wounded for whom the city hospitals are primarily destined. Sweeping changes are contemplated.

49. Coexistence of Scarlet Fever and Typhoid.—Farnarier analyzes a total of 75 cases of the coexistence of these two diseases that have been published since 1833. The list includes 39 absolutely beyond criticism, and on these his monograph is based. The typhoid infection is the preceding one in the vast majority of cases, but occasionally the onset of the two diseases is simultaneous and the scarlet fever masks the typhoid, until as convalescence from the former occurs, the signs of the latter are revealed. The prognosis of the combination does not seem to be more unfavorable than of typhoid fever alone. In the 39 cases the mortality was only 10 per cent. In the fatal cases death was induced by the hemorrhagic form of the scarlet fever in 2 instances, by uremia in another, and by perforation during a relapse of the typhoid in the fourth. He does not regard this low mortality as more than a mere coincidence—not establishing that the two diseases attenuate each other. In each of these fatal cases the typhoid had preceded the scarlet fever. Among the complications noted have been ear troubles in 2; albuminuria in one, and consecutive typhoid phlebitis in another, also albuminuria from the onset of the scarlet fever in one case, with an attack of acute nephritis as the typhoid fever declined. Marrotte's patient exhibited edema of face, hands and feet with oliguria, but no albuminuria. In 2 cases convalescence was disturbed by suppuration of cervical glands. Whenever a scarlet fever shows atypical features, especially during its decline, the possibility of an unrecognized typhoid should be borne in mind, and the prognosis be guarded until this question is settled. Inversely, when a scarlatiniform eruption occurs during typhoid fever it should not be ascribed as a matter of course to a toxic or infectious erythema, but the possibility of scarlet fever should not be forgotten. The consequences of overlooking such a possibility might entail very serious consequences both for the patient and his environment. Nineteen articles are reviewed, including one by Hektoen.

50. Segregation of Urine by Massage of the Kidneys.—Giordano and Nicolich have been applying massage of the kidney as a means of testing its functions. The former has the subject recline for a few hours and then squeezes one kidney with massage of the region and of the back and side of the abdomen. The urine is then withdrawn from the bladder and the other kidney is manipulated in the same way. If the urine obtained from each kidney differs in its composition, there is evidently some difference in the condition of the organs. Nicolich rinses and evacuates the bladder and then introduces a catheter. He then massages one kidney; if the organ is normal clear urine drips from the catheter, the drops coming more frequently the more energetic the massage. He then massages the other kidney in the same way. When it is pathologic the urine, clear at first, soon becomes turbid. He was able to locate the diseased kidney in 2 cases in which he applied this functional test, and the diagnosis was confirmed by the nephrectomy. When the patient voids turbid urine while clear urine is obtained under massage of both kidneys then the lesion can not be in the kidneys, but must be sought elsewhere, as he had occasion to establish in one instance.

51. Elective Action of N Rays.—Charpentier found that most of the alkaloids and poisons emit N rays, and also that the action of these substances on the phosphorescent screen was enhanced by the vicinity of another source for the N rays. The idea then occurred to him to construct a phosphorescent screen containing some of these substances in addition to the phosphorescent sulphid. These screens are acted on by the physiologic N rays, but in an elective manner. The organ which acts most energetically on a given screen is always that organ which has the strongest affinity for the alkaloid used in making the screen. For example, the digitalin screen is rendered most luminous when exposed to the N rays from the heart; the pilocarpin screen when exposed to the glands, atropin to the heart—whose action atropin accelerates—while the atropin screen becomes less luminous when exposed to the N rays from the glands. The strychnin screen is most luminous when exposed to the spinal cord, the apomorphin screen with the medulla, the nicotin screen with the protuberantia, the santonin screen with the visual centers, etc., etc. See editorial pages.

of 100 c.c. during the tempestuous onset of an acute nephritis. Baccelli repeats the venesection if necessary.—Ed.]

66. **Asepsis of Hands During Operations.**—Rydygier believes in repeated rinsing of the hands in saline solution during operations, and thinks that if both operator and assistants acquire this habit of frequently repeated mechanical cleansing of the hands gloves will not be needed.

67. **Intravenous Infusion. Technic and Resuscitation of Babe.**—Schücking gives a picture of an apparatus which has done him good service for twenty-seven years in intravenous infusion. A tube with faucet projects tapering to a point inside a glass receptacle with an outlet below. As the fluid enters through the tube above all air bubbles escape and rise to the top of the receptacle while the fluid passes on and out below. He adds parenthetically that he has succeeded in reviving still another newborn babe in almost hopeless asphyxia by infusing into the umbilical vein 30 gm. of a 1 per cent. solution of sodium saccharate to which 6 drops of a 1/10 alcoholic solution of camphor had been added. He was unsuccessful in another case, probably because he waited too long before resorting to this simple measure. See his previous article in The Journal, xxxix, page 454.

68. **Elimination of Pneumothorax in Intrathoracal Operations by the Pneumatic Chamber.**—Under this heading The Journal, page 930, described the air chamber devised by Sauerbruch, "scientific assistant" at Mikulicz' clinic, to exclude the pressure of the atmosphere and thus enable surgical intervention inside the thorax without dread of the collapse of the lungs. When the atmospheric pressure is eliminated the lung action continues practically unmodified whether the thorax is opened or not. He stated that his communication was only a preliminary note, but it was soon followed by an article from Brauer and Petersen, who announced an "essential simplification of the Sauerbruch method." Sauerbruch here claims priority for this "simplification" and shows that the idea had occurred to him and had been applied in the clinic before the Heidelberg professors had thought of it. It is a reversal of the air chamber technic. Instead of placing the patient or animal in the air chamber with his head outside and eliminating the atmospheric pressure inside the chamber, the head is placed in the air chamber, the body outside, and the atmospheric pressure inside the air chamber is artificially raised to an over-pressure of 10 mm. mercury. This insures the maintenance of the physiologic difference between the pressure within and without the lungs, and the lung action continues unmodified when the thorax is opened. The animals in his experiences continued to breathe naturally notwithstanding that both lungs were freely exposed to the air. The objection to this technic was found to be that the person administering the anesthetic inside the air chamber was subjected to such inconvenience that this mode of avoiding pneumothorax was temporarily abandoned until a larger air chamber could be procured. The new one now building is made to use with either a minus or plus atmospheric pressure. The Heidelberg clinicians propose to use instead of the air pump an oxygen tank to induce the over-pressure. These communications are given a separate supplement in the *Centralblatt* with leaded type. Sauerbruch adds in conclusion that he is convinced that by the elimination of atmospheric pressure all kinds of operations on the brain, eye, heart, spine and diaphragm may be facilitated. In his work on the lungs he aims to supply the difference of atmospheric pressure as if the air chamber were merely an enlargement of the natural pleura. The Brauer and Petersen article was published in the *Zeitschrift f. phys. Chemie*, xli, No. 4. [Mikulicz contributes an article on this subject to the *Deutsche med. Wochft.* of April 7, recapitulating the above points. He urges the general adoption of the word thoracotomy as an equivalent for laparotomy, as the air chamber allows ample access to the thorax, which thus becomes as accessible as the abdomen. The operator must, however, be careful to make the closure of the wound opening into the thorax absolutely air tight, as otherwise pneumothorax is liable to develop later. On this account he advises to make the opening in an interspace without resecting the ribs. The incision must be exactly in the center of the interspace to allow perfect suturing afterward. The ribs can then usually be pushed apart sufficiently to allow ample access. If not, one can be broken with the hands, inside its periosteum, which obviates the necessity for suturing it later. He uses a retractor to hold the ribs out of the way similar to an ordinary lid holder. The third to the seventh interspaces are best adapted for this intervention. The protruding lung is held back in the same way as the intestines during a laparotomy. The intercostal musculature is then carefully sutured, if necessary throwing the catgut around the rib for a better hold. The muscles above are then sutured in tiers with catgut and the skin with silk. Resection of the ribs may be unavoidable in some cases. His article is not concluded.—Ed.]

71 *Removal [illegible] Way of Vagina. R. Gradenwitz ([illegible] eines Uretersteines auf vaginalem Wege.

69. **Position of Arms During Narcosis.**—Rothe is convinced that postoperative paralysis of the arm is a more frequent occurrence than is generally recognized, as also slighter parectic conditions, etc. The brachial plexus is compressed between the clavicle and the first rib when the arms are raised, and he seeks to avoid this by fastening the arms parallel and close to the trunk. He uses a couple of arm bands for each arm, one for the forearm and the other for the upper portion. The corresponding bands are fastened together under the table. It is impossible to keep watch of the pulse with the arms thus bound down, but this, he thinks, is immaterial, presenting arguments in favor of this view and citing the English anesthetists who have long since discarded the control of the pulse as superfluous. He quotes Czempin's work on chloroform narcosis as the standard authority on this subject.

70. **Avoidance of Postoperative Cystitis.**—Baisch made the discovery that the death of a certain patient fourteen months after ablation of a uterine cancer—the general health being good during the interval—was due to a progressive postoperative cystitis. He believes that it is more than probable that many deaths which have been attributed to recurrence of the cancer or to an intercurrent affection, were in reality due to an unsuspected postoperative cystitis or its sequels. There has not been a single instance of postoperative cystitis in the 31 cases operated on by the Wertheim technic since he instituted systematic rinsing out of the bladder every time the catheter is used. Only one of the 31 was able to urinate spontaneously from the first, and 5 died in the course of the week with no manifestations of cystitis. Of the remaining 25 one had suffered from severe nephritis before the intervention and it proved impossible to avert the cystitis in her case. In 2 the last drops of urine were a trifle cloudy and the colon bacillus was found, but vanished in a few days with no further signs of trouble. The others—some of whom required catheterization for eighteen days before spontaneous urination was restored—all escaped any bladder trouble. Even after spontaneous urination is restored it is at first imperfect and the bladder is not completely emptied, thus favoring infection. Hence it follows that these irrigations must be faithfully kept up until the bladder function is completely restored to normal and the last drops of urine are spontaneously evacuated. Wertheim himself now injects a solution of protargol or boric acid as a prophylactic measure. By this means all the germs introduced by the catheter are killed at once before they have time or opportunity to do any damage.

71. **Removal of Stone in Ureter by Way of Vagina.**—General narcosis was not considered necessary. The bulging portion of the ureter was reached through an incision in the anterior wall of the vagina and pushed down and out through another incision just above. The lower portion of the parametrium had been previously incised between two ligatures. The ureter was incised and after a calculus the size of a cherry-stone had been removed the ureter was sutured with the finest thread, over the sound at first, the other tissues with catgut. The

operation lasted an hour, but the patient did not moan once. Convalescence was smooth, without fever, and in three weeks the patient was dismissed as cured of the present trouble. The cystoscope showed both ureters functioning normally. The two scars in the vagina could scarcely be felt, the urine was limpid, there was no trace of a fistula and there had been no change in these conditions when the patient was last seen four months later. She was a woman of 43 with organic heart disease, a v-para.

84. Medical Treatment of Tubercular Peritonitis.—Miserocchi reports 14 cases of tubercular peritonitis cured by medical means alone. His experience has been still larger than this, but he mentions only those cases in which the interval since has been long enough to speak of a permanent cure. Measles or pertussis had preceded the tuberculosis in more than 78 per cent. of the cases. This confirms Rander's figures. He found measles or pertussis, or both, in the antecedents of 83 per cent. of 352 tuberculous children. Miserocchi emphasizes this fact as of preponderant importance for the prophylaxis of tuberculosis. In 8 of his 14 cases there was ascites; in 4 a mixed, fibrous-ascitic-caseous form, and in 2 the fibrocaseous form. Treatment was by the use of iodin internally and externally. The children were put to bed and given a milk diet at first, with disinfection of the digestive tract, plenty of fresh air and gradually increasing nourishment to forced feeding. The children were cured as a matter of course even when merely out-patients. both in cases in which the peritonitis was the only manifestation of the disease and also in those in which the pleura or lungs were probably affected. Iodo-tannic syrup was given internally with an iodo-iodid salve rubbed into the abdomen. The ascites was absorbed and the palpated nodules retrogressed. The communication issues from Cattaneo's clinic at Parma.

93. Grocco's Paravertebral Triangle.—When one side of the thorax is filled with a pleuritic effusion the contents are pushed over on the opposite side. There is an area of dullness over the rear of the thorax in these conditions coinciding with the center of the spine at the top, spreading out a little toward the bottom on the side of the effusion, and forming almost a square on the other side, although the general outline of the whole is rather triangular. The conditions in health and with artificially induced effusions of varying amounts are given in 7 diagrams. The pleural sac presses evenly against the spine, which explains the dullness over it. The effusion sometimes collects more at the back and sometimes extends more evenly all around the wall of the thorax. When the latter occurs there is liable to be a retrosternal area of dullness, which Banti has described as also a sign of pleuritic effusion.

99. Silver Fluorid as an Antiseptic.—A large number of Italian clinicians have been using silver fluorid with great success in the treatment of erysipelas, smallpox and puerperal infection. Some proclaim that it is the most powerful antiseptic at our disposal in comparison with its harmlessness for the tissues. Its action is purely local. Jaja has recently reported a severe case of confluent smallpox treated with a 1/10,000 solution of this drug with complete recovery in twenty-two days. He applies it as a spray under pressure, which is a peculiarly convenient form in smallpox, anthrax, etc., and allows the drug to penetrate into the deepest crevices. The vesicles were all aborted and none passed beyond the serous stage. The disease otherwise continued its regular course, unmodified by the applications. The spray was applied four times a day for fifteen days. The abortion of the vesicles in this case has convinced Jaja that the suppuration of the pustules is not an integral part of smallpox, but is due to secondary infection, an avoidable complication from the presence of pus cocci which are readily destroyed by the fluorid. In erysipelas the fluorid cured both the local and the general symptoms. De Marchis reports 16 cases of puerperal infection treated by daily intra-uterine irrigation with a 1/4,000 solution of the fluorid, using as much as three quarts of the solution, until it came away clear. Three to six irrigations generally succeeded in banishing the fever, but in one case eight were required and in another eleven. The sole inconvenience is that the solution spots the linen, but this is trifling in comparison with its many advantages. Mirto of Pavia also commends it as the most valuable of all disinfectants for the uterus and vagina.

101. Gelatin in Aneurisms of the Aorta.—Forlanini relates experiences with the therapeutic use of gelatin which establish that it has a marked influence on the arterial pressure, reducing it considerably when it is pathologically high. In a case of aneurism consecutive to smallpox he obtained prompt benefit from administration of gelatin either by the mouth or subcutaneously. The arterial pressure was materially reduced. This effect was never apparent when the arterial pressure was only slightly above normal.

102. Latent Meningitis in Pneumonia.—Curlo describes 2 cases of pneumonia in which the delirium and other symptoms observed were explained by unsuspected lesions of meningitis found at the necropsy. Out of a total of 1,350 pneumonia patients, in 20 these lesions were found in the meninges postmortem. This is a proportion of 1.9 per cent., while others have published percentages of .08 to 2 per cent. The prognosis of these cases should be guarded. The sole manifestation is usually the delirium with possibly convulsive attacks indicating trouble in the lower portion of the rolandic region. Two cases are described in detail.

103. Serum Treatment of Mixed Infection.—Castronuovo reviews nearly a dozen series of tests of antistreptococcus and antidiphtheria serum administered simultaneously to rabbits. The effects were not striking, but when anti-pneumococcus serum was given with the antidiphtheria serum, in cases of mixed infection from these germs, the results were highly successful.

104. **Retrograde Drainage of Brain Wounds.**—Cavazzani's patient was a young man who had been shot through the head, the bullet entering the right cheek and emerging in the left temple, severing the left optic nerve. The entire track left by the bullet was drained with a strip of iodoform gauze passed entirely through it and renewed every two or three days, for fifteen days. The gauze was then gradually withdrawn, a little at a time, allowing the wound to heal behind it. The fundus of the eye showed no lesions, but there was acute delirium during the first few days and at night for a time afterward. As the wound healed memory returned, particularly for past events, while for recent ones it was still defective. These disturbances, however, soon subsided and the psychic balance seemed completely restored, testifying to the fact that the functional lesion of the frontal lobe from the bullet had been merely a kind of paralysis from the trauma or shock, and not due to destruction of tissue. A year later the only visible traces of the accident were a slight interference with the movements of the jaw, and a slight depression in the temple; the muscular apparatus of the left eye was apparently intact, but mild epilepsy developed eight months after the accident, about one seizure a month, each preceded by a sensory acoustic aura which the patient described as a diabolic confusion of sounds and rumblings, followed by loss of consciousness and a day or so of prostration. There was no initial cry, no convulsion and no tongue symptom. At other times the hearing was normal. The memory was perfect except for the week or so preceding and following the accident. He had also lost the memory for many tunes which he had formerly been able to whistle. The mild character of the symptoms observed in this case was evidently due to the remarkable escape of the more important structures in this region as the bullet passed, but also in great measure to the prompt and effectual retrograde drainage, as Cavazzani calls it, passing completely through the head from one end of the bullet track to the other, but in the opposite direction to that followed by the bullet. By drawing the gauze through the passage it was cleared of clots and other débris while the iodoform insured antisepsis. The strip of gauze was wide enough to keep it in soft contact with the walls without compressing them. The effusion of serum into the gauze must have had a tendency to wash out into it all scraps of injured tissue which were thus easily removed as the gauze was drawn along. The case shows that the injured anterior end of the first left temporal convolution belongs to the zone of association, and that the impressions are arranged by allied groups on the cortex of this zone and are not diffuse and mixed as is probably the case in the anterior or frontal zone. In conclusion he relates the clinical history of a case of abscess in the right frontal lobe, consecutive to frontal sinusitis, with complete recovery after operative intervention. The symptoms had been slight mental disturbances, conjugated rotation of the head and eyes and jacksonian epilepsy in the domain of the facial nerve and left brachial plexus and in the adjacent regions, especially affecting some center of phonation. The mental disturbances were evidently a sign of paralysis from destruction, while the other symptoms indicated irritation or hyperfunction. Both cases are analyzed in detail, and the localization data compared.

105. **Neurasthenia in Relation to Nephroptosis.**—Ruggi admits the existence of an internal secretion in the kidneys. This secretion, in harmonious action with the other secretions, etc., of the organism, establishes what we call health, and any disproportion between these internal secretions causes sickness. When one of these secretions is lacking, as, for instance, after ovariectomy, the consequent disturbances may possibly be combated by organ therapy, not of the missing organ, but to reduce or stimulate the secretion of some other organ or organs which in these conditions are functioning out of proportion to the total output of internal secretions. When the kidneys are producing their internal secretion in deficient amount or in excess, as in case of a kidney irritated by displacement, the patient is liable to suffer in various ways which may be grouped as neurasthenia. The morbid condition may require treatment to increase the amount of the internal secretion of the displaced organ or to stimulate other organs to keep pace with its increased secretion. The partial ischemia, the ischemic neuralgias noted in case of nephroptosis, the oliguria or anuria observed in patients after nephropexy or during renal colics from calculi, may all be regarded as the effect of the deportation of renal material by way of the circulation—they are not merely the reflex phenomena they are usually considered. The sensory nerves in case of ptosis of the kidney are liable to be unduly stimulated, and this in turn entails psychic or nervous disturbances in the predisposed. He cites as an example of this condition the constant vague pain in the lumbar region noted in tardy neurasthenia after removal of the uterus and annexes. He suggests the practicability of treating neurasthenia consecutive to castration, by organ therapy addressed to the internal secretion of the kidney, which, under these circumstances, becomes either absolutely or relatively excessive.
